Medical Properties and Uses. Potassium permanganate, first brought to the notice of the profession in 1857, by Mr. Condy, as a powerful disinfectant, has been proved to be very efficient not only in lessening fetid odors from organic sources, but also in destroying the sources of the odor. It acts by oxidizing, but, as it can yield up only the oxygen within it, its powers are limited. Further, it is a comparatively expensive substance, so that it is very rarely employed when any considerable mass of material is to be affected. It also has the further disadvantage of staining the skin, clothes, etc.; but the stain may be removed with oxalic acid. It is frequently used in the treatment of *fetid* and *gangrenous ulcers*, *hospital gangrene*, *abscesses*, *carbuncles*, and *wounds* of all kinds, of fetid discharges from the mucous membrane, as in *ozæna*, *otorrhœa*, *gonorrhœa*, and *leucorrhœa*, and of *diphtheritic affections;* and it has proved serviceable even in *cancerous ulcers*. As a local stimulant it has also been used in *chronic* and *indolent ulcers*. In all these cases it is applied to the diseased surface in solution of various strengths, according to the effect desired. In concentrated solution it is capable of acting as a caustic, and therefore requires caution. With the view to its caustic action, it may be sprinkled on the diseased surface by means of a pepper-box, or applied in saturated solution. As a disinfectant or stimulant lotion it may be of various strengths, from one to twenty grains to the fluidounce of water. In preparing any solution of permanganate for use, it is of the utmost importance to avoid organic matters. Internally, the medicine has been used in *diphtheria*, *scarlatina*, and various *zymoses*, and in *dyscrasia*, but is probably of no service. It is plain that any moderate amounts of the permanganate must be decomposed by the organic matters of the mouth, œsophagus, and stomach before absorption. Nevertheless, the value of the permanganate in *atonic amenorrhœa*, first asserted by Prof. Sydney Ringer, has been strongly corroborated by Dr. Fordyce Barker and other clinicians. It should be given in doses of from one to two grains (0·065–0·13 Gm.), after meals, unless it produce too much gastric uneasiness. Pills made with an excipient of cacao butter or resin cerate, or compressed tablets of the pure salt, may be employed.

Potassium permanganate acts as an oxidizant much more rapidly upon some organic substances than upon others, by virtue of which fact it is a valuable antidote, notably in the treatment of morphine-poisoning and of snake-poisoning. In the latter condition a concentrated solution of it should be injected freely and immediately into the part which has been bitten. (For cases, see *Medical Record*, 1894.) In morphine-poisoning it acts only upon the alkaloid in the stomach, but should be given from time to time during the continuance of the symptoms in order to destroy any morphine which may have been eliminated from the blood into the stomach.

POTASSII SULPHAS. U. S., Br. Potassium Sulphate.

K_2SO_4; 173·88. (PŌ-TĂS'SĬ-Ī SŬL'PHĂS.) K_2SO_4; 174.

"Potassium Sulphate, K_2SO_4, may be obtained by purifying the crude salt, or by the interaction of sulphuric acid and potassium chloride or certain other potassium salts." *Br.*

Sulphate of Potash; Vitriolated Tartar; Kalium Sulfuricum, *P. G.;* Sulfas Potassicus, s. Kalicus, Tartarum Vitriolatum, Arcanum Duplicatum, Sal de Duobus; Sulfate de Potasse, Potasse vitriolée, *Fr.;* Schwefelsaures Kali, *G.;* Solfato di Potassa, *It.*

Several chemical processes give rise to potassium sulphate as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of nitre and sulphuric acid; in the decomposition of magnesium sulphate by potassium carbonate, in one of the processes for preparing magnesium carbonate; in the manufacture of sulphuric acid; in the manufacture of potassium bichromate; and in the decomposition of potassium tartrate by calcium sulphate. When nitric acid is obtained by calcining a mixture of nitre and ferrous sulphate, the residue consists of ferric oxide and potassium sulphate, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The impure potassium sulphate with sulphur, forming the residue of the combustion of sulphur and nitre in making sulphuric acid, is employed in the manufacture of alum. The *kainite* of the Stassfurt salt-beds is a native double potassium and magnesium sulphate, combined with magnesium chloride, and the *schœnite*, a double potassium and magnesium sulphate, with 6 molecules of water. To obtain potassium sulphate, the former mineral is exposed to the air; it deliquesces, and as soon as the soluble magnesium chloride has been run off, the remaining salt is partially decomposed by boiling water, so that on cooling the difficultly soluble sulphate separates out. About 12,000 tons of the potassium magnesium sulphate so obtained are annually put upon the market for use in fertilizers. The production of *kainite* at Stassfurt, in Germany, amounted in 1896 to 856,290 tons, valued at $2,989,736, and in 1897 to 995,821 tons, valued at $3,496,204.

According to the directions of the former Br. Pharmacopœia, the acid sulphate which remains after the distillation of nitric acid is brought to the neutral state by saturation, in boiling solution, with slaked lime. The solution is then filtered, to separate the calcium sulphate, and potassium carbonate is added at the boiling temperature, to remove lime and calcium sulphate. It is again filtered, then either neutralized or rendered slightly acid with diluted sulphuric acid, and finally, having been evaporated to a pellicle, is set aside for twenty-four hours to crystallize. The manufacturer of tartaric acid who avails himself of calcium sulphate to decompose potassium tartrate forms potassium sulphate as a collateral product. For the manner in which the latter salt may be economically crystallized for use, see *A. J. P.*, xxiii. 343.

Properties. As officially described, it is in "hard, colorless, transparent, six-sided, rhombic prisms terminated by pyramids, or a white powder, odorless, and having a somewhat bitter, saline taste. Permanent in the air. Soluble in about 9·5 parts of water at 15° C. (59° F.), and in 4 parts of boiling water; insoluble in alcohol. When heated, the crystals decrepitate. At a bright red heat they fuse, and at a white heat the salt suffers partial decomposition. The aqueous solution is neutral to litmus paper. The aqueous solution of the salt yields a copious yellow precipitate with sodium cobaltic nitrite test-solution, and a white, crystalline precipitate with excess of tartaric acid test-solution. When held in a non-luminous flame on a clean platinum wire, the salt should at once impart to the flame a violet color (absence of *sodium*). The aqueous solution (1 in 20) should remain unaffected by the addition of an equal volume of hydrogen sulphide test-solution either before or after acidulation with hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.); or by the addition of a small amount of ammonium sulphide test-solution (absence of *zinc*, *iron*, *aluminum*, etc.). Other portions of the aqueous solution should not be rendered turbid by the addition of ammonium oxalate test-solution (absence of *calcium*); or of sodium phosphate test-solution and ammonia water (*magnesium*); or of silver nitrate test-solution (*chloride*). The addition of potassium ferrocyanide test-solution should produce neither a blue (absence of *iron*) nor a red color (*copper*)." *U. S.* "In color-

less hard rhombic prisms terminated by six-sided pyramids; decrepitates strongly when heated; soluble in 10 parts of cold and 4 parts of boiling *water;* insoluble in *alcohol* (90 per cent.). The salt affords the reactions characteristic of potassium and of sulphates. Each gramme dissolved in *water* and acidulated with *hydrochloric acid,* gives, with *solution of barium chloride,* a white precipitate, which, when washed and dried, should weigh 1·339 grammes. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, or nitrates, and only the slightest reactions with the tests for chlorides. The aqueous solution has no action on *litmus* (absence of acid potassium sulphate)." *Br.* It consists of two atoms of potassium combined with the dyad group, SO_4, characteristic of sulphuric acid.

The *plate-sulphate of potassa*, so well described by Prof. Penny, of Glasgow, is, when pure, the double potassium and sodium sulphate, having the formula $3K_2SO_4 + Na_2SO_4$. It is so called from the circumstance of being crystallized in hard thick cakes, or slabs, consisting of successive crops of crystals. It is a technical product from kelp, and may be formed by allowing successive quantities of concentrated kelp-lye to run into coolers, there to crystallize in successive layers, the mother-liquor being drawn off by a siphon after the deposit of each layer. (*Phil. Mag.*, Dec. 1855.) For the mode of preparing and using *Sal Polychrestum*, *Potassii Sulphas cum Sulphure*, or *Sulphate of Potassa with Sulphur*, see U. S. D., 15th ed., p. 1187.

Medical Properties and Uses. Potassium sulphate is a mild purgative, operating usually without heat, pain, or other symptom of irritation. In small doses, of from a scruple to half a drachm (1·3–1·95 Gm.), it operates as an aperient; in larger doses, of four or five drachms (15·5–19·4 Gm.), it acts slowly as a purge. On the continent of Europe it is frequently given as an aperient after delivery, and for the purpose of drying up the milk. Potassium sulphate is undoubtedly a powerful irritant, and capable of producing fatal poisoning: an ounce and a half (46·6 Gm.) of it are said to have caused death. It is, like the nitrate and the chlorate, more dangerous when not given in sufficiently dilute solution. (See *Am. Jour. Med. Sci.*, N. S., vii. 88.)

POTASSII TARTRAS. Br. Potassium Tartrate.

$K_2C_4H_4O_6.H_2O$; 469·36. (PŌ-TĂS'SĪ-Ī TĂR'TRĂS.) $K_2C_4H_4O_6.H_2O$; 470.

"Normal Potassium Tartrate, $(CHOH)_2(COOK)_2,H_2O$, is obtained by neutralizing Acid Potassium Tartrate with potassium carbonate." *Br.*

Tartrate of Potash; Soluble Tartar; Kali Tartaricum, *P. G.;* Tartras-potassicus, s. Kalicus; Tartarus Tartarisatus, Tartarus Solubilis; Tartrate de Potasse, Tartre soluble, Sel végétal, *Fr.;* Neutrales Weinsaures Kali, *G.*

This salt was dropped at the 1890 revision of the U. S. Pharmacopœia; it is retained in the 1898 revision of the British authority.

In the U. S. 1870 process* the excess of acid in the bitartrate is saturated by the potassa of the carbonate, the carbonic acid is liberated with effervescence, and the neutral potassium tartrate is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring, and the addition continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the acid tartrate, since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline; and hence, if inadvertently too much bitartrate has been used, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered, in order to separate calcium tartrate, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to insure a slow refrigeration; and after remaining at rest for several days the crystals begin to form. In order that the crystallization should proceed favorably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in the process, as that metal is apt to discolor the salt.

Potassium tartrate is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of calcium carbonate.

* "Take of Carbonate of Potassium *sixteen troyounces;* Bitartrate of Potassium [cream of tartar], in fine powder, *thirty-six troyounces*, or *a sufficient quantity;* Boiling Water *eight pints.* Dissolve the Carbonate of Potassium in the Water; then gradually add Bitartrate of Potassium to the solution until it is completely saturated, and boil. Filter the liquid, evaporate it until a pellicle forms, and set it aside to crystallize. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S.* 1870.

This generates an insoluble calcium tartrate, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties. Potassium tartrate was officially described in the U. S. P. 1880 as in "small, transparent or white, monoclinic crystals, or a white powder, somewhat deliquescent, odorless, having a saline, slightly bitter taste, and a neutral reaction. Soluble in 0·7 part of water at 15° C. (59° F.), and in 0·5 part of boiling water; almost insoluble in alcohol. When heated, the salt melts, then chars, and evolves inflammable vapors having the odor of burnt sugar. On moderate ignition, it leaves a blackened residue of an alkaline reaction, strongly effervescing with acids. A concentrated, aqueous solution of the salt yields a white, crystalline precipitate on the addition of acetic acid. With test-solution of nitrate of silver it yields a white precipitate which becomes black on boiling." For medical use it should be crystallized; but as it ordinarily occurs in commerce it is a white granular powder, obtained by evaporating the solution to dryness while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is not known to be purposely adulterated; but, if obtained by evaporation to dryness, it is liable to contain an excess of potassium carbonate or bitartrate, when it will have either an alkaline or an acid reaction. It is decomposed by all the strong acids, and by many acidulous salts, which cause the precipitation of minute crystals of potassium bitartrate, by abstracting one atom of alkali from the salt. Barium chloride or lead acetate occasions a white precipitate of barium or lead tartrate, distinguishable from the sulphates of those bases by being wholly soluble in dilute nitric acid. "A 10 per cent. aqueous solution should yield no precipitate with test-solution of ammonium oxalate (abs. of calcium). On adding nitric acid to a one per cent. solution of the salt, until the precipitate first formed is redissolved, the resulting solution should yield no precipitate with test-solution of barium chloride (sulphate), and, at most, only a cloudiness with test-solution of silver nitrate (limit of chloride). If 2·938 Gm. of Potassium Tartrate are ignited till gases cease to be evolved, the alkaline residue should require, for complete neutralization, not less than 25 C.c. of the volumetric solution of oxalic acid (corresponding to 100 per cent. of pure Potassium Tartrate)." *U. S.* 1880. "In small colorless four- or six-sided prisms. It is soluble in its own weight of *water*. It affords the reactions characteristic of potassium and of tartrates. Each gramme of the dry salt, heated to redness till gases cease to be evolved, should leave an alkaline residue, which, when treated with *water*, filtered, and well washed, yields a clear solution requiring for exact neutralization 8·4 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, or iron, and only the slightest reactions with the tests for calcium, magnesium, sodium, chlorides, or sulphates. The aqueous solution has no action on *litmus* (absence of acid potassium tartrate)." *Br.* Potassium tartrate is composed of two atoms of potassium combined with the dyad group $C_4H_4O_6$ characteristic of tartaric acid. Two molecules of this salt are crystallized with one molecule of water. It is a neutral salt. According to Berzelius, the crystals contain no water of crystallization.

Medical Properties. Potassium tartrate is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to *febrile diseases*, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce (3·9–31·1 Gm.).

PRUNUM. U. S., Br. Prune.

(PRŪ'NŬM.)

"The dried fruit of Prunus domestica, Linné (nat. ord. Rosaceæ)." *U. S.* "The dried ripe fruits of Prunus domestica, Linn., var. Juliana, DC." *Br.*

Prunes; Pruneaux, *Fr.;* Pflaumen, Zwetschen, *G.;* Pruni, *It.;* Ciruelas secas, *Sp.*

Gen. Ch. Calyx inferior, bell-shaped, deciduous, with five obtuse, concave segments. *Petals* five, roundish, concave, spreading, larger than the segments of the calyx, into the rim of which they are inserted. *Filaments* awl-shaped, nearly as long as the corolla, from the rim of the calyx within the petals. *Anthers* short, of two round lobes. *Ovary* superior, roundish. *Style* of the length of the stamens. *Stigma* orbicular, peltate. *Drupe* roundish or elliptical. *Nut* hard, somewhat compressed, of one cell, and two more or less distinct sutures with an intermediate furrow. *Leaves* rolled up when young. *Lindley.*

Prunus domestica. Willd. *Sp. Plant.* ii. 995; Woodv. *Med. Bot.* p. 520, t. 187. The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We give merely the specific character. "*Peduncles* subsolitary; *leaves* lanceolate-ovate, convolute;

branches not spiny." The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruits only that are official. They are officially described as "oblong or subglobular, about 3 Cm. long, shrivelled, blackish blue, glaucous; the sarcocarp brownish yellow, sweet and acidulous; putamen hard, smooth, or irregularly ridged; the seed almond-like in shape, but smaller, and of a bitter-almond taste." *U. S.* The prunes brought to our market come chiefly from the south of France, the best from Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *Prune de Saint-Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep violet color. It is prepared by drying in the sun, after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine*, and *Reine Claude* or *greengage*. An inferior sort is brought from Germany.

Prunes have a feeble odor, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. The following is given as the average of nine analyses of dried prunes. Water 29·30 per cent., nitrogenous material 2·35 per cent., fat 0·53 per cent., free acid 2·72 per cent., sugar 44·35 per cent., other nitrogen-free material 17·89 per cent., woody fibre (not including the stone) 1·48 per cent., ash 1·38 per cent. (König, *Nahrungsmittel*, ii. 397, 1880.) In Hungary a kind of brandy (*Zwetschenbranntwein*), containing about 40 per cent. of alcohol, is obtained from them, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar equal to that of the cane.

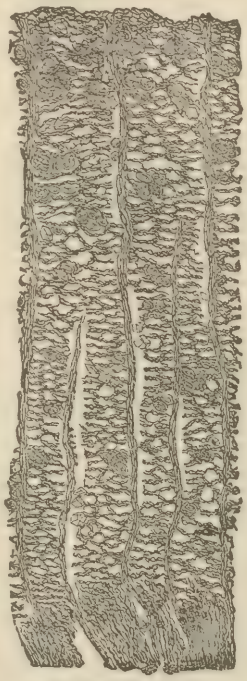
Medical Properties and Uses. Prunes are laxative and nutritious, and, stewed with water, form an excellent diet in *costiveness*. Imparting their laxative property to boiling water, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is used in the preparation of laxative confections. Too largely taken, they are apt to occasion flatulence, griping, and indigestion.

PRUNUS VIRGINIANA. U. S. (Br.) Wild Cherry.

(PRŪ'NŬS VĬR-ĢĬN-Ī-A'NĄ.)

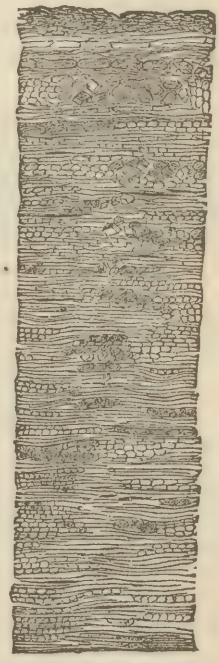
"The bark of Prunus serotina, Ehrhart (nat. ord. Rosaceæ), collected in autumn." *U. S.*
"The bark of Prunus serotina, collected in autumn." *Br.*

Pruni Virginianæ Cortex, *Br.*, Virginian Prune Bark; Rum Cherry, Wild Black Cherry; Ecorce de Cerisier de Virginie, *Fr.*; Wildkirschenrinde, *G.*



CERASUS. See *Laurocerasus.*

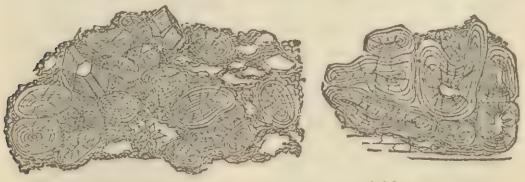
The genus Prunus now includes the plums, almonds, peaches, apricots, and cherries, and comprises about one hundred and twenty species. They are generally distributed in the temperate regions of the northern hemispheres. In the United States there are about twenty-five indigenous species.



Cerasus (not *Prunus*) *serotina.* Loiseleur. *Nouv. Duhamel* (1812), v. 3. De Candolle. *Prodrom.* ii. 540.—*Prunus serotina.* Ehrhart; Watson's *Bibliographical Index.*—*Cerasus virginiana.* Michaux, *Fl. Bor.-Am.*, i. 285. The name *P. virginiana* was applied by Miller (*Dict.*, ed. 8, No. 3), and not Linnæus, to *P. serotina* Ehr. *P. virginiana* L., commonly called *wild cherry* or *choke cherry*, is distinguished from *P. serotina* Ehr., known more properly as *wild black cherry*, by the following characteristics: *P. virginiana* L. has deciduous calyx lobes; oblong-obovate pointed endocarp (or stone); leaves broadly oval to oblong-obovate, and usually abruptly acuminate; inner bark with a rather disagreeable odor. *P. serotina* Ehr. has persistent calyx lobes; the endocarp (or stone) oblong-obovate, usually gradually acuminate; leaves oblong or lanceolate-oblong, usually gradually acuminate; the inner bark and leaves possess an aromatic odor. The British name for the bark is misleading; Virginian Peach Bark or Virginian Almond Bark would have been no more of a misnomer. The official species is, according to Michaux, one of the largest productions of the American forest. Individuals were seen by that botanist on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semicircularly in thick narrow plates. The leaves are alternate, oval-oblong, or

lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green; the petioles are furnished with one or more reddish conspicuous glands. The flowers are small, white, and occur in long erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple color. For a paper on the structure of species of Prunus, by Prof. E. S. Bastin, see *Proc. A. P. A.*, 1895, 211.

This tree is distributed from Nova Scotia south to Florida, and westward to Dakota, Nebraska, Kansas, Indian Territory, and Eastern Texas. It extends along the mountain ranges of Western Texas, Mexico, and Pacific regions of Central America, Colombia, and Peru. In the United States it was once common throughout the Appalachian region. In the nighborhood of Philadelphia it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint which deepens with age. The leaves have been found by Prof. Procter to yield volatile oil and hydrocyanic acid on distillation, and in such proportion that a water distilled from them might with propriety be substituted for the cherry-laurel water. (*Proc. A. P. A.*, 1858, 325.) The fruit has a sweetish, astringent, bitter taste, and is much used in some parts of the country to impart flavor to spirituous liquors. The bark is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. The revisers of the Pharmacopœia believe with J. S. Perot that the bark is stronger when collected in autumn than in the spring: from a portion gathered in April Perot obtained 0·0478 per cent. of hydrocyanic acid, and from another in October 0·1436 per cent., or about three times as much. (*A. J. P.*, xxiv. 111.) The bark should be preferred recently dried, as it deteriorates by keeping. Prof. A. B. Stevens (*Proc. A. P. A.*, 1895, 226; 1896, 215), after testing many specimens, reached the conclusion that bark procured from different parts of the same tree varied in the yield of hydrocyanic acid, the value being in this order: 1, root; 2, twigs; 3, trunk; the bark from young trees yielding more glucoside than that from old trees. Jos. L. Lemberger (*A. J. P.*, 1872, 303) has found that the bark yields the darkest infusion in April, October, and November, and the lightest in January and August; and believes that he has demonstrated that the coloration is due to tannic acid. According, therefore, to this investigation, tannic acid is most abundant in the bark in October and November. On the other hand, Grace E. Cooley (*A. J. P.*, August, 1897) concludes that there is more tannic acid in the bark during the active growth of the spring than in the autumn. She further states that in the spring and autumn the bark contains its maximum percentage of starch; so that if the bark, whether powdered or whole, contains much starch in its parenchymatous cells, it has been collected after the time of leaf-fall in the autumn or before the unfolding of the leaves in the spring.



Prunus virginiana, transverse section.

Prunus virginiana, longitudinal section.

Properties. Wild-cherry bark is officially described as follows. "In curved pieces or irregular fragments, 2 Mm. or more thick, outer surface greenish-brown, or yellowish-brown, smooth and somewhat glossy, marked with transverse scars; if the bark is collected from old wood and deprived of the corky layer, the outer surface is nut-brown and uneven; inner surface somewhat striate or fissured. Upon maceration in water it develops a distinct bitter-almond odor; its taste is astringent, aromatic and bitter. The bark of the very large and of the very

small branches is to be rejected." *U. S.* It is brittle and pulverizable, presenting a reddish gray fracture, and affording a fawn-colored powder. In the fresh state, or when treated with water, it emits an odor resembling that of peach-leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavor of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavor and its medical virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat. On microscopical examination it is seen to be chiefly composed of brown parenchymatous tissue containing numerous crystals, sometimes aggregated into tufts (see cut), and enclosing numerous groups of very thick-walled sclerenchymatous cells of irregular outline. The medullary rays are usually distinct. From an analysis by Dr. Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red coloring matter, salts of lime and potassa, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. Prof. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water with amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, the agency of another principle, probably analogous to if not identical with *emulsin* or the *synaptase* of Robiquet, is also essential; and, as this principle becomes inoperative at the boiling temperature, we can understand how decoction may interfere with the virtues of the bark. (*A. J. P.*, x. 197.) Phlorizin has not been found, so that the tonic property which is undoubtedly possessed by the bark must reside either in the portion of amygdalin which may remain undecomposed, in the pure volatile oil resulting from its reaction with water, or in some yet undiscovered principle. (*Ibid.*, xxiv. 111.) That the last of these inferences is the correct one would seem to be proved by an experiment by Prof. Procter, who found the bitterness of an extract of the bark to remain after it had been wholly deprived of amygdalin. The sedative properties of the bark depend upon the hydrocyanic acid which it yields. Stevens and Judy (*A. J. P.*, 1895, 482 and 534) find that the thick bark contains more amygdalin and consequently yields more HCN than the thin bark. The thick bark contains amygdalin, etc., 4·12 per cent., and HCN from 0·32 to 0·35 per cent.; the thin bark, amygdalin, etc., 3·16 per cent., and HCN from 0·24 to 0·27 per cent.

Prunus virginiana, showing raphides.

R. Rother (*A. J. P.*, 1887, p. 286), in searching for the fluorescent principle of wild-cherry bark, obtained a reddish crystalline substance, soluble in water, chloroform, ether, and alcohol, the solution of which fluoresced strongly on addition of ammonia. Rother says that it does not agree in crystalline form with mandelic acid, but may be a derivative of it. Prof. F. B. Power and Henry Weimer, on the other hand, state that the bark does not contain crystallizable amygdalin, that the ferment principle is not emulsin, and that it cannot be isolated by an analogous process. The bitter principle, which appears to be the fluorescent substance, has the character of a glucoside, and crystallizes in colorless needles. (*Western Druggist*, 1887, p. 331.)

Medical Properties and Uses. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, this bark is theoretically adapted to the treatment of diseases in which *debility of the stomach* or of the *system* is united with *general or local irritation;* and when very largely taken it diminishes the action of the heart. Thus, Dr. Eberle found copious draughts of the cold infusion, taken several times a day, and continued for nearly two weeks, to reduce his pulse from seventy-five to fifty strokes in the minute. But in the doses usually prescribed, the remedy is too feeble to exert much influence. Nevertheless, it has been much employed in this country, in the *hectic fever* of *scrofula* and *consumption*. The dose of the infusion, which is properly directed in the Pharmacopœia to be prepared with cold water, is two or three fluidounces (60 or 90 C.c.); of the fluid extract, a fluidrachm (3·7 C.c.); and of the syrup,* half a fluidounce (15 C.c.).

* *Tinctura Pruni Virginianæ B. P. C.* Take of wild-cherry bark (from *Prunus serotina*, Elliott, collected in autumn), in No. 20 powder, 4 ounces; distilled water, 7½ fluidounces. Macerate for twenty-four hours, in a closed vessel, and add: Rectified spirit, 12½ fluidounces. Macerate for seven days; then express, filter, and add sufficient proof spirit to make 1 pint. (*A. P. A.*, 1888, p. 285.)

PULSATILLA. U. S. Pulsatilla.

(PŬL-SĄ-TĬL'LĄ.)

Herba Pulsatillæ, *P. G.;* Pulsatille, Coquelourde, *Fr.;* Küchenschelle, *G.*

"The herb of Anemone Pulsatilla and of Anemone pratensis, Linné (nat. ord. Ranunculaceæ), collected soon after flowering. It should be carefully preserved, and not be kept longer than one year." *U. S.*

This is a large genus of small herbal plants growing in almost all the temperate countries of the world, and probably possessed very generally of the acrid rubefacient properties of the Ranunculaceæ. The *A. ludoviciana*, an American species, growing in Minnesota and other parts beyond the Mississippi, has been employed with supposed advantage by Dr. W. H. Miller, of St. Paul, in chronic diseases of the eyes, in cutaneous eruptions, and in syphilitic affections. Mr. A. W. Miller also found anemonin in it. (*A. J. P.*, 1862, p. 300; see, also, *A. J. P.*, xlv. 299.) *A. nemorosa*, which is common in Europe and the United States, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis.

A. pulsatilla. Linnæus.—*Pulsatilla vulgaris.* Mill. This plant has its flower-stalk from five to eight inches high, with large solitary flowers, having six dull violet-purple sepals, which are very downy on the exterior, and an involucre which is at first near the flower and afterwards becomes more remote. The radical leaves are on long footstalks, and two or three times divided into long linear segments. It is a very common plant in England and Northern Europe.

*A. pratensis,** which affects Southern Europe, is especially distinguished by its having the involucre so close to the flower as to assume the appearance of a calyx.

A. patens, Linné, var. *nuttalliana*, Gray, was formerly recognized as a source of pulsatilla. Dr. Gray affirms that this plant is more like *A. pulsatilla* than like *A. patens*, and that it is a distinct species, to which the name of *A. nuttalliana*, Gray, should be given. It grows a span high, with an erect flower having five to seven purplish spreading sepals.

Properties. The characters of the herb are sufficiently given in the description of the plant. Dr. Beckurts obtained *anemone camphor* by treating in each case the aqueous distillate of *A. nemorosa*, *A. pratensis*, and *A. pulsatilla* with chloroform. It is unstable, splitting easily into anemonin and anemonic acid, the latter, when treated with alkalies, yielding *anemoninic acid*, $C_{10}H_{12}O_6$. (*P. J. Tr.*, 1885, 365.) The formula of anemonin is $C_{10}H_8O_4$. It is only slightly soluble in cold alcohol, but readily soluble in hot alcohol, and very slightly soluble in boiling ether or water. It is decomposed at temperatures above 152° C. (305·6° F.), and dissolves in alkalies with yellow color, changing at the same time into *anemonic acid*, $C_{10}H_{10}O_5$. Hanriot (*Journ. Chem. Soc.*, 1887, 843) has further studied anemonin. He finds that it melts at 156° C. and decomposes at 270° C., with partial sublimation. With zinc-dust or hydriodic acid in sealed tubes, a small quantity of a hydrocarbon is formed which appears to be cymene or cumene. If anemonin be dissolved in chloroform and treated with excess of bromine, it will yield the compound $C_{10}H_8Br_4O_4$; this crystallizes from benzene in octohedra which do not melt without decomposition. When treated with nascent hydrogen in an acid solution, anemonin yields *hydroanemonin*, $C_{10}H_{12}O_4$, which crystallizes from boiling petroleum in large colorless laminæ which contain 1 mol. of H_2O, melt at 78° C., and distil without decomposition at from 210°–212° C. under a pressure of 10 Mm. Hydroanemonin is much more stable than anemonin.

Medical Properties and Uses. Our knowledge of the physiological and therapeutic action of pulsatilla is very incomplete. The fresh drug appears to be a violent local irritant; given by the mouth in sufficient dose it acts as a gastro-intestinal irritant, producing severe vomiting and purging, attended with much pain and followed by hebetude, wide-spread tremors, urino-genital irritation, hæmaturia, dyspnœa, and paralysis. The dried drug is said to be much less active than is the fresh herb, although it has been used to some extent as a sternutatory, and must therefore at least share the irritant properties of the green plant.

According to the researches of Noel and Lambert (*Arch. de Pharmacodyn.*, 1897), anemonin is essentially different in its physiological effects from the fresh pulsatilla, the latter being an energetic muscle-poison, affecting not only the muscles of voluntary life but attacking the muscle-fibres of the heart and arteries, and therefore notably affecting the circulation. On the other hand, anemonin is affirmed to act solely on the central nervous system, not affecting

* Baron Störck thought that he found *A. pratensis* useful in *amaurosis* and other *complaints of the eye*, in *secondary syphilis*, and in *cutaneous diseases*.

the motor nerves or the muscles. It causes, when injected into the lower animals, increasing paralysis, sometimes convulsions, both of which symptoms are due to an action upon the spinal cord. Bronevski (*Med. Press*, Aug. 11, 1886) declares that anemonin not only acts upon the nerve-centres but also upon the heart itself. The strength of commercial anemonin varies very greatly, no doubt according to the purity of the product. Broudgeest gives the fatal dose for the rabbit as two hundred milligrammes per kilogramme, whilst in Noel and Lambert's experiments 0·16 gramme per kilogramme was required to kill the guinea-pig.

The value and range of therapeutic application of pulsatilla remain uncertain. Bovet, many years ago, claimed that it was a reliable analgesic and uterine stimulant in *dysmenorrhœa* and *ovarian irritation*. He asserted that it is better to use the fresh drug, anemonin being very inactive. The dose of anemonin he stated to be from five-sixths to one and one-half grains a day, in divided amounts. It has also been claimed that pulsatilla has a peculiar influence upon the male genital organs, and that it is useful in *epididymitis* or *orchitis*, and even in *urethritis*. The drug is still used to some extent in dysmenorrhœa, but its possession of active powers is doubtful. Given in infinitesimal amounts, with due ceremony as to dilution, tumblers, and spoons, to credulous, hysterical women, it may be sometimes of service; but whether it has any other application is by no means certain. In one or two trials very carefully made in nervous dysmenorrhœa it has failed in our hands absolutely. In similar manner Dr. Robert J. Carter, after careful trial, entirely condemns the drug in the treatment of irritation or inflammation of the male genitalia. Pulsatilla was also at one time believed to have specific influence upon almost all of the mucous membranes, but to be especially valuable in affections of the respiratory passages, such as *bronchitis*, *asthma*, *whooping-cough*, etc.

The preparation employed by Störck was an extract of the herbaceous part of the plant, which was given in the dose of one or two grains daily, gradually increased to twenty grains or more. Noel and Lambert especially commend a fluid extract made from the fresh herb, of which they state that from seventy-five to one hundred and twenty-five minims may be exhibited in the course of twenty-four hours. The dose of the dried powder is commonly given as from two to three grains (0·13–0·2 Gm.), but probably much larger amounts can be safely taken.

PULVERES. Powders.

(PŬL'VĘ-RĒȘ.)

Poudres, *Fr.*; Pulver, *G.*

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure in closely-stoppered bottles. In many instances it is also important to exclude the light, which exercises a deleterious influence over numerous medicines when minutely divided. This may be done by coating the bottles with black varnish. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.*

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept,—the former because they render the preparation damp and liable to spoil,

* With regard to keeping powders in well-stoppered bottles, it is asserted by M. Hérouard, a French pharmaceutist, that this plan, instead of preserving *some* powders, tends to their more speedy and certain change. Whatever pains may be taken in drying drugs previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air: and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel and determines a movement of fermentation; and even cryptogamic growths appear in some instances. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a blue or gray color, so as to exclude the light, while the air has exit or entrance through the porous walls. Whatever may be our theoretical opinions on the point, M. Hérouard asserts the fact, as the result of observation, that powders keep best in this way, and his statement coincides with our own experience. The powders may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. (*Journ. de Pharm.*, Août, 1862, p. 98.) From these statements the inference may be drawn that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulverization, before being enclosed; and many, such as ergot, rhubarb, etc., should be kept in paper boxes or cartons.

the latter because they are apt to become rancid and impart an unpleasant odor and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in waxed paper or other impervious covering; and the same remark is applicable to volatile powders, as ammonium carbonate and camphor. The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar. For many powders the *cachet de pain* affords the best method of administration.*

In the act of powdering, the whole substance in the mortar should not be beaten till completely pulverized, as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated, so that there is a loss both of time and of material. The proper plan is to sift off the fine powder after a short continuance of the process, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.

PULVIS AMYGDALÆ COMPOSITUS. Br. Compound Powder of Almonds.

(PŬL'VIS Ą-MĬG'DĄ-LÆ CŌM-PŎŞ'Ī-TŬS.)

Confectio Amygdalæ, *Lond.;* Conserva Amygdalarum, *Ed.;* Confection of Almond; Conserve d'Amandes, *Fr.;* Mandelconserve, *G.*

"Sweet Almonds, 8 *ounces* (Imperial) or 200 grammes; Refined Sugar, in powder, 4 *ounces* (Imp.) or 100 grammes; Gum Acacia, in powder, 1 *ounce* (Imp.) or 25 grammes. Steep the Almonds in water until their skins can easily be removed; when thus blanched, dry them as far as possible with a soft cloth, and then thoroughly by exposure in a warm place for twenty-four hours; rub them lightly in a mortar to a smooth consistence; mix the Gum Acacia and the Sugar; add this mixture, gradually, to the bruised Almonds; rub the whole to a coarse powder." *Br.*

This is the old *Almond Confection* under a new name. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready-made. But, from its liability to be injured by keeping, it was omitted from the U. S. Pharmacopœia, which directs the emulsion of almond to be made immediately from the ingredients.

PULVIS ANTIMONIALIS. U. S., Br. Antimonial Powder. [James's Powder.]

(PŬL'VIS ĂN-TĮ-MŌ-NĮ-Ā'LĮS.)

Pulvis Antimonii Compositus, Pulvis Jacobi; Poudre antimoniale de James, *Fr.;* James's Antimonpulver, *G.*

"Antimony Oxide, *thirty-three grammes* [or 509 grains]; Precipitated Calcium Phosphate, *sixty-seven grammes* [or 2 ounces av., 159 grains]; To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them intimately." *U. S.*

"Antimonious Oxide, 1 *ounce* (Imperial) or 25 grammes; Calcium Phosphate, 2 *ounces* (Imp.) or 50 grammes. Mix." *Br.*

This preparation has been introduced into the U. S. Pharmacopœia as a substitute for the different forms of antimonial powder formerly official with the British Colleges, and because of its revived employment at the present time. The official preparations are identical. In order that the subject may be properly understood, it will be necessary to introduce a notice of the powder as formerly directed to be prepared by the London and Dublin Colleges; the process of the Edinburgh College was so similar to the London that it does not require special consideration.

Antimonial Powder of the London College. The following was the London process. "Take of Tersulphate of Antimony, powdered, *a pound;* Horn shavings *two pounds.* Mix, and throw them into a red-hot crucible, and stir constantly until vapor ceases to arise. Rub the residue to powder, and put it into a crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the remaining powder until it is as fine as possible." *Lond.*

* *Cachets.* These very useful articles are wafers made of unleavened bread in such a manner that they offer a concavity, so that when two are placed face to face there is a space in which a powder may be contained. They are of different sizes and capacities, the largest readily holding as much as ten grains of quinine. In filling them, one wafer is placed upon a board, and the requisite amount of medicine is put in it; then a second wafer, whose interior margin has been wetted, is laid upon the first and pressed down upon it. When taken, they should be dipped in water, placed immediately upon a teaspoon containing a little water, and swallowed with a gulp of fluid. For most powders of disagreeable taste, cachets afford the best method of administration.

This preparation consists mainly of calcium bone-phosphate, or calcined bone, mixed with antimonous acid, and is intended to furnish a substitute for the celebrated nostrum of Dr. James, an English physician who died in 1776, and after whom the original preparation was called *James's powder*. Dr. Pearson, of London, found the genuine powder, on analysis, to consist of calcium phosphate and oxidized antimony, and, guided by his results, devised the formula adopted by the London College. By burning the materials directed by the College, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized; while the horn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination the charcoal is dissipated, leaving only the calcium phosphate of the horn mixed with the antimony oxide.

The antimonial powder made by this formula is a tasteless, inodorous, gritty powder, of a dull white color. As often prepared, it is insoluble in water; but usually a small portion, consisting of antimonite and acid calcium phosphate, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonous acid and calcium phosphate; for when its soluble constituents are absent the teroxide is absent also.

The only essential difference between the official and the Dublin powder is that the ingredients of the former are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. The official powder is, of course, much more easily prepared, and less liable to uncertainty from any error in the process.*

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was often prescribed in febrile diseases, with a view to its diaphoretic effect. According to Dr. A. T. Thomson, it is advantageously given in *acute rheumatism*, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several *cutaneous affections*. The estimation in which this preparation is held is very various; but it is generally admitted that, as formerly prepared, it was very uncertain in the percentage of antimony teroxide, and consequently in its activity: it was this uncertainty that led to its omission from the U. S. P. of 1830.

The antimonial powder at present official is exempt from the objection of irregularity of composition. Nevertheless, as it depends for its greater or less energy on the presence or absence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable. The dose, as a diaphoretic, is from three to eight grains (0·20–0·52 Gm.) every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic. Dr. Jonathan Osborne has found the teroxide, given separately in three-grain (0·20 Gm.) doses, evening and night, to cause in some cases nausea and vomiting, in others mild purgation. (*P. J. Tr.*, 1855, p. 331.)

PULVIS AROMATICUS. U. S. (Br.) Aromatic Powder.

(PŬL'VIS ĂR-Ō-MĂT'Ĭ-CŬS.)

Pulvis Cinnamomi Compositus, *Br.*; Compound Powder of Cinnamon; Poudre aromatique, *Fr.*; Aromatisches Pulver, *G.*

"Ceylon Cinnamon, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Ginger, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Cardamom, deprived of the capsules and crushed, *fifteen grammes* [or 231 grains]; Nutmeg, in No. 20 powder, *fifteen grammes* [or 231 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Cardamom and Nutmeg with a portion of the Ceylon Cinnamon, until they are reduced to a fine powder; then add the remainder of the Cinnamon and the Ginger, and rub them together until they are thoroughly mixed." *U. S.*

"Cinnamon Bark, in powder, 1 *ounce* (Imperial) or 25 grammes; Cardamom Seeds, in powder, 1 *ounce* (Imp.) or 25 grammes; Ginger, in powder, 1 *ounce* (Imp.) or 25 grammes. Mix." *Br.*

The Aromatic Powder of the U. S. P. 1890 does not differ essentially from that formerly official. The British and American powders now closely resemble each other. The present British formula differs from that of 1864 in the substitution of ginger for nutmeg, cloves, and saffron, and especially in the absence of sugar, which in the latter constituted two-thirds of the whole, having probably been added in order that, by the addition of a little water to the

* Mr. Michael Donovan believes that none of the official formulas fairly represent James's powder, and gives an elaborate history of this celebrated proprietary medicine, and a method for its preparation, in *P. J. Tr.*, 1869.

powder, an aromatic confection might be readily prepared, without the necessity of keeping it. It is obvious that this end may be as effectually attained by the addition of a little syrup to the present powder.* The cardamom seeds should always be separated from their capsules before being weighed; and the powder, when prepared, should be kept in well-stoppered bottles. The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains (0·65–1·95 Gm.), in cases of *enfeebled digestion with flatulence;* but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such mixtures are commonly called *spice plasters.* The following is a good formula. Take of ginger, cloves, cinnamon, and black pepper, each, in powder, an ounce; tincture of ginger half a fluidounce; honey a sufficient quantity. Mix the powders, and then add the tincture and honey, so as to form a stiff cataplasm; or the mixed powder may be distributed in a thin flannel bag, quilted in position, and the whole wet with bathing whiskey when applied and covered with oiled silk.

PULVIS CATECHU COMPOSITUS. Br. Compound Powder of Catechu.

(PŬL'VIS CĂT'Ĕ-CHŪ CŌM-PŎS'Ĭ-TŬS.)

"Catechu, in powder, 4 *ounces* (Imperial) or 100 grammes; Kino, in powder, 2 *ounces* (Imp.) or 50 grammes; Krameria Root, in powder, 2 *ounces* (Imp.) or 50 grammes; Cinnamon Bark, in powder, 1 *ounce* (Imp.) or 25 grammes; Nutmeg, in powder, 1 *ounce* (Imp.) or 25 grammes. Mix." *Br.*

The dose of this agreeable preparation is from fifteen to thirty grains (1–1·95 Gm.).

PULVIS CRETÆ AROMATICUS. Br. Aromatic Powder of Chalk.

(PŬL'VIS CRĒ'TÆ ĂR-Ō-MĂT'Ĭ-CŬS.)

"Cinnamon Bark, in powder, 4 *ounces* (Imperial) or 80 grammes; Nutmeg, in powder, 3 *ounces* (Imp.) or 60 grammes; Cloves, in powder, 1½ *ounces* (Imp.) or 30 grammes; Cardamom Seeds, in powder, 1 *ounce* (Imp.) or 20 grammes; Refined Sugar, in powder, 25 *ounces* (Imp.) or 500 grammes; Prepared Chalk, 11 *ounces* (Imp.) or 220 grammes. Mix." *Br.*

This is the former "Aromatic Powder" of the Br. Pharmacopœia, with the addition of chalk and elision of saffron. It is a warm stimulant and astringent, as well as antacid, and is well calculated for *diarrhœa* connected with acidity and without inflammation. In such a combination, however, the due proportion and even the choice of the ingredients vary so much with the symptoms that they might well be left to extemporaneous prescription. Dose, from thirty to sixty grains (1·95–3·9 Gm.), in mucilage or sweetened water, frequently repeated.

PULVIS CRETÆ AROMATICUS CUM OPIO. Br. Aromatic Powder of Chalk with Opium.

(PŬL'VIS CRĒ'TÆ ĂR-Ō-MĂT'Ĭ-CŬS CŬM Ō'PĬ-Ō.)

"Aromatic Powder of Chalk, 9¾ *ounces* (Imperial) or 39 grammes; Opium, in powder, ¼ *ounce* (Imp.) or 1 gramme. Mix. This Powder contains 2½ per cent. of Opium." *Br.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in *diarrhœa;* and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the powder contain a grain of opium. In the *diarrhœa* of adults from ten to twenty grains (0·65–1·3 Gm.) may be given for a dose, and repeated several times a day, or after each evacuation.

PULVIS CRETÆ COMPOSITUS. U. S. Compound Chalk Powder.

(PŬL'VIS CRĒ'TÆ CŌM-PŎS'Ĭ-TŬS.)

"Prepared Chalk, *thirty grammes* [or 1 ounce av., 25 grains]; Acacia, in fine powder, *twenty grammes* [or 309 grains]; Sugar, in fine powder, *fifty grammes* [or 1 ounce av., 334 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them intimately." *U. S.*

This is a new official powder. It has been introduced for the purpose of having on hand, in a convenient form, the dry powders necessary to make chalk mixture. (See *Mistura Cretæ.*)

* *Aromatic Sugar.* Mr. Wm. L. Turner proposed a mode of obtaining the effects of the aromatic powder in certain cases where the use of the powder itself would be inconvenient. He prepared an aromatic sugar by submitting eight ounces of the freshly prepared powder to percolation with stronger alcohol to exhaustion, pouring the percolate over eight ounces of sugar, and evaporating at a low heat. The sugar thus prepared may be added to mixtures, solutions, etc., requiring aromatic addition. (*A. J. P.*, March, 1869, p. 118.)

This powder will be found, however, a very convenient basis for administering chalk in powder; and it will be easy to direct the addition of morphine, kino, pepsin, bismuth subnitrate, or any other suitable agent.

PULVIS EFFERVESCENS COMPOSITUS. U. S. (Br.) Compound Effervescing Powder. [Seidlitz Powder.]

(PŬL'VIS ĔF-FĔR-VĔS'CĔNS CŌM-PŌS'Ĭ-TŬS.)

Pulvis Sodæ Tartaratæ Effervescens, *Br.;* Effervescent Tartarated Soda Powder; Pulveres Effervescentes Aperientes, *U. S.* 1870; Seidlitz Powders; Pulvis Aërophorus Laxans, s. P. Aërophorus Seidlitzensis, *P. G.;* Poudre gazifère purgative, Poudre de Seidlitz, *Fr.;* Abführendes Brausepulver, Seidlitzpulver, *G.*

"Sodium Bicarbonate, in fine powder, *thirty-one grammes* [or 1 ounce av., 41 grains]; Potassium and Sodium Tartrate, in fine powder, *ninety-three grammes* [or 3 ounces av., 123 grains]; Tartaric Acid, in fine powder, *twenty-seven grammes* [or 417 grains]. Mix the Sodium Bicarbonate intimately with the Potassium and Sodium Tartrate, divide the mixture into *twelve equal parts*, and wrap each part in a separate paper of some pronounced color, as *blue*. Then divide the Tartaric Acid also into *twelve equal parts*, and wrap each part in a separate paper of a color distinctly different from that used for wrapping the mixture, as *white*. Keep the powders in well-closed vessels." *U. S.**

"Sodium Potassium Tartrate, in dry powder, 120 *grains* or 7·77 grammes; Sodium Bicarbonate, in dry powder, 40 *grains* or 2·59 grammes. Mix. Wrap in blue paper. Tartaric Acid, in dry powder, 38 *grains* or 2·46 grammes. Wrap in white paper. *Dose, for a draught.*—The alkaline powder (in blue paper) dissolved in nearly half a pint of cold or warm water, and the acid powder (in white paper) then added." *Br.*

The British Pharmacopœia, under the name of *Pulvis Sodæ Tartaratæ Effervescens*, introduced in the 1885 revision these well-known powders, which are universally known as Seidlitz Powders. Though named from the saline springs of Seidlitz, in Bohemia, Seidlitz Powders do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains about thirty-five grains (2·25 Gm.) of tartaric acid, the other about forty grains (2·58 Gm.) of sodium bicarbonate mixed with about two drachms (7·75 Gm.) of Rochelle salt. The acid powder is usually put into a white paper, the alkaline into a blue paper, which latter should not be colored by aniline; a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to be dissolved by the moisture and absorbed into the substance of the paper, thus altering the due proportion of the ingredients. We have known the whole of the contents of the white paper thus to disappear in the course of two or three years. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity; and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the sodium bicarbonate, by which sodium tartrate is produced, adding somewhat to the laxative property of the draught, and carbonic acid escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution. These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbonic acid eliminated. They are especially adapted to *febrile cases* with a somewhat irritable stomach. One pair of them will generally operate slightly; but, if required, two may be given at once, or the dose may be repeated every three or four hours till the desired effect is produced. The flavor may sometimes be advantageously improved by adding syrup of ginger, orange peel, or lemon to one of the solutions before admixture; and most persons prefer to dissolve the salts in very cold water, the saline taste being thereby greatly diminished. A lowering of the temperature always takes place, due to the solution of the salts.

* *Pulveres Effervescentes. Effervescing Powders. Soda Powders. Pulvis Aërophorus Anglicus*, P. G.: *Poudre gazeuse, P. aërophore, P. de Seltz*, Fr.; *Brausepulver*, G. "Take of Bicarbonate of Sodium, in fine powder, *three hundred and sixty grains;* Tartaric Acid, in fine powder, *three hundred grains*. Divide each of the powders into twelve equal parts, and keep the parts, severally, of the Bicarbonate and of the Acid in separate papers of different colors." *U. S.* 1870. *Soda Powders* consist, severally, of twenty-five grains (1·565 Gm.) of the acid in one paper, and thirty (1·95 Gm.) of the bicarbonate in the other. They are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively, into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms (7·5–11·25 C.c.) of syrup of ginger or orange peel to the water, before dissolving the powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a sodium tartrate, while the carbonic acid escapes with effervescence. The effervescing powders are refrigerant and slightly laxative, and afford an agreeable and refreshing drink, suitable to febrile complaints, and generally very acceptable to the stomach.

PULVIS ELATERINI COMPOSITUS. Br. Compound Powder of Elaterin.

(PŬL'VIS Ē-LĂT-Ē-RĪ'NĪ CŌM-PŎS'Ī-TŬS.)

"Elaterin, 5 *grains* or 1 gramme; Milk Sugar, 195 *grains* or 39 grammes. Triturate in a mortar until a fine powder is produced." *Br.*

This is a new official in the British Pharmacopœia, identical with the trituration of elaterin of the United States Pharmacopœia, except that it is of but one-fourth its strength. The dose is given in the British Pharmacopœia as from one to five grains (0·06–0·25 Gm.).

PULVIS GLYCYRRHIZÆ COMPOSITUS. U. S., Br. Compound Powder of Glycyrrhiza.

(PŬL'VIS GLĬÇ-ĬR-RHĪ'ZÆ CŌM-PŎS'Ī-TŬS.)

Pulvis Liquiritiæ (Glycyrrhizæ) Compositus, s. P. Pectoralis Kurellæ, *P. G.;* Poudre de Réglisse composée, *Fr.;* Brustpulver, *G.*

"Senna, in No. 80 powder, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Glycyrrhiza, in No. 80 powder, *two hundred and thirty-six grammes* [or 8 ounces av., 142 grains]; Washed Sulphur, *eighty grammes* [or 2 ounces av., 360 grains]; Oil of Fennel, *four grammes* [or 62 grains]; Sugar, in fine powder, *five hundred grammes* [or 17 ounces av., 279 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Oil of Fennel thoroughly with about one-half of the Sugar, then add the remainder of the Sugar and the other ingredients, and mix thoroughly. Finally pass the powder through a No. 60 sieve, and keep it in well-closed vessels." *U. S.*

"Senna, in fine powder, 2 *ounces* (Imperial) or 50 grammes; Liquorice Root, in fine powder, 2 *ounces* (Imp.) or 50 grammes; Fennel Fruit, in fine powder, 1 *ounce* (Imp.) or 25 grammes; Sublimed Sulphur, 1 *ounce* (Imp.) or 25 grammes; Refined Sugar, in powder, 6 *ounces* (Imp.) or 150 grammes. Mix." *Br.*

This official preparation, which was introduced into the U. S. P. 1880, was identical with that of the German Pharmacopœia; and in the 1885 revision of the British Pharmacopœia the preparation was made nearly to correspond, being slightly deficient in senna. The U. S. P. 1890 has replaced the powdered fennel with Oil of Fennel, increasing the proportion of powdered liquorice correspondingly,—which is an improvement, as powdered fennel is variable in quality: great care should be used, however, to employ only fresh oil of fennel. The object of the oil of fennel is patent, but the advantage to be gained by the use of washed sulphur in the proportion of only 8 per cent. must be purely imaginary. In our opinion, an improvement would be the substitution of two parts each of powdered cinnamon and cloves for four parts of the sugar, to correct the griping effect which is frequently produced. It is used as an agreeable laxative in the dose of from thirty to sixty grains (1·95–3·9 Gm.).

PULVIS IPECACUANHÆ ET OPII. U. S. (Br.) Powder of Ipecac and Opium. [Dover's Powder.]

(PŬL'VIS ĬP-Ē-CĂC-Ū-ĂN'HÆ ĔT Ō'PĪ-Ī.)

Pulvis Ipecacuanhæ Compositus, *Br., U. S.* 1870; Pulvis Ipecacuanhæ Opiatus, s. Pulvis Doweri, *P. G.;* Poudre de Dower, *Fr.;* Dower'sches Pulver, *G.*

"Ipecac, in No. 60 powder, *ten grammes* [or 154 grains]; Powdered Opium, *ten grammes* [or 154 grains]; Sugar of Milk, in No. 30 powder, *eighty grammes* [or 2 ounces av., 360 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub them together into a very fine powder." *U. S.*

"Ipecacuanha Root, in powder, ½ *ounce* (Imperial) or 10 grammes; Opium, in powder, ½ *ounce* (Imp.) or 10 grammes; Potassium Sulphate, in powder, 4 *ounces* (Imp.) or 80 grammes. Mix." *Br.*

The substitution of powdered sugar of milk for potassium sulphate in crystals as formerly used cannot be said to have improved this well-known powder, except in making it more agreeable to the taste. The U. S. 1890 process should have directed the powder to be sifted, in order to secure a thorough blending of the ingredients: the sifting should on no account be omitted by the operator. The potassium sulphate or the sugar of milk serves to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound depend, the potassium sulphate being preferable on account of the greater hardness of its particles. They also serve to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composi-

tion, though called Dover's Powder, does not precisely correspond with that originally recommended by Dr. Dover, which was prepared as follows. Four ounces of potassium nitrate and the same quantity of potassium sulphate were mixed in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, were mixed with the other ingredients. This process was adopted in a former French Codex, and has been retained with little change in the present. For a method of valuing Dover's Powder, by Prof. A. B. Prescott, see *A. J. P.*, Dec. 1878.

This powder is an admirable anodyne diaphoretic, applicable to all cases, not attended with much fever, cerebral disease, or sick stomach, in which there is an indication for diaphoresis, especially in painful affections, or in those connected with unhealthy discharges. It is admirably adapted to the *phlegmasiæ*, particularly *rheumatism* and *pneumonia*, *dysentery*, *diarrhœa*, etc., when not contra-indicated by existing symptoms. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel. Ten grains of the powder contain one grain of opium. The dose is from five to fifteen grains (0·33–1 Gm.), given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be promoted by warm drinks, such as lemonade or balm tea.

PULVIS JALAPÆ COMPOSITUS. U. S., Br. Compound Powder of Jalap. [Pulvis Purgans.]

(PŬL'VIS JA-LĀ'PÆ CŌM-PŌŞ'I-TŬS.)

"Jalap, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Potassium Bitartrate, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub them together until they are thoroughly mixed." *U. S.*

"Jalap, in powder, 5 *ounces* (Imperial) or 100 grammes; Acid Potassium Tartrate, in powder, 9 *ounces* (Imp.) or 180 grammes; Ginger, in powder, 1 *ounce* (Imp.) or 20 grammes. Mix." *Br.*

The rubbing of the bitartrate with the jalap is thought to favor its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in *dropsy*, and in *scrofulous diseases of the joints and glands*. The dose of the powder is from thirty grains to a drachm (1·95–3·9 Gm.).

PULVIS KINO COMPOSITUS. Br. Compound Powder of Kino.

(PŬL'VIS KĪ'NŌ CŌM-PŌŞ'I-TŬS.)

Pulvis Kino cum Opio, *Br.* 1864; Powder of Kino and Opium.

"Kino, in powder, 3¾ *ounces* (Imperial) or 75 grammes; Opium, in powder, ¼ *ounce* (Imp.) or 5 grammes; Cinnamon Bark, in powder, 1 *ounce* (Imp.) or 20 grammes. Mix. This Powder contains 5 per cent. of Opium." *Br.*

This is an anodyne astringent powder, useful in some forms of *diarrhœa*, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances. Twenty grains contain one grain of opium. The dose is from five to twenty grains (0·33–1·3 Gm.).

PULVIS MORPHINÆ COMPOSITUS. U. S. Compound Powder of Morphine. [Tully's Powder.]

(PŬL'VIS MŌR-PHĪ'NÆ CŌM-PŌŞ'I-TŬS.)

"Morphine Sulphate, *one gramme* [or 15·5 grains]; Camphor, *nineteen grammes* [or 293 grains]; Glycyrrhiza, in No. 60 powder, *twenty grammes* [or 309 grains]; Precipitated Calcium Carbonate, *twenty grammes* [or 309 grains]; Alcohol, *a sufficient quantity*. To make *sixty grammes* [or 2 ounces av., 51 grains]. Rub the Camphor with a little Alcohol, and afterwards with the Glycyrrhiza and Precipitated Calcium Carbonate, until a uniform powder is produced. Then rub the Morphine Sulphate with this powder, gradually added, until the whole is thoroughly mixed. Finally, pass the powder through a No. 40 sieve, and transfer it to well-stoppered bottles." *U. S.*

This official compound powder originated with Dr. Wm. Tully, of New Haven, Conn., who devised it as a substitute for Dover's Powder. It is very necessary to comply strictly with the

directions of Dr. Tully in its preparation, *i.e.*, to mix the ingredients thoroughly and then sift the powder, and this last direction has been included in the official formula of 1890. The diaphoretic action depends largely upon the intimate admixture of the ingredients. There is the one-sixtieth of a grain of morphine sulphate in one grain of the powder. The dose is ten grains (0·65 Gm.), containing one-sixth of a grain (0·01 Gm.) of morphine sulphate.

PULVIS OPII COMPOSITUS. Br. Compound Powder of Opium.

(PŬL'VIS Ō'PI-Ī CŌM-PŌS'I-TŬS.)

"Opium, in powder, 1½ *ounces* (Imperial) or 30 grammes; Black Pepper, in powder, 2 *ounces* (Imp.) or 40 grammes; Ginger, in powder, 5 *ounces* (Imp.) or 100 grammes; Caraway Fruit, in powder, 6 *ounces* (Imp.) or 120 grammes; Tragacanth, in powder, ½ *ounce* (Imp.) or 10 grammes. Mix. This Powder contains 10 per cent. of Opium." *Br.*

This seems to have been introduced in order to have at hand all the dry ingredients of the Confection of Opium. (See *Confectio Opii.*) Ten grains (0·65 Gm.) of the powder contain one grain (0·065 Gm.) of opium.

PULVIS RHEI COMPOSITUS. U. S., Br. Compound Powder of Rhubarb.

(PŬL'VIS RHĒ'Ī CŌM-PŌS'I-TŬS.)

Gregory's Powder; Pulvis Magnesiæ cum Rheo, s. P. Infantum, s. P. Antacidus, *P. G.;* Poudre de Rhubarbe composée, *Fr.;* Kinderpulver, *G.*

"Rhubarb, in No. 60 powder, *twenty-five grammes* [or 386 grains]; Magnesia, *sixty-five grammes* [or 2 ounces av., 128 grains]; Ginger, in No. 60 powder, *ten grammes* [or 154 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub them together until they are thoroughly mixed." *U. S.*

"Rhubarb Root, in powder, 2 *ounces* (Imperial) or 50 grammes; Light Magnesia, 6 *ounces* (Imp.) or 150 grammes; Ginger, in powder, 1 *ounce* (Imp.) or 25 grammes. Mix. If a less bulky powder be desired, Heavy Magnesia may be employed." *Br.*

This is a good laxative antacid, well adapted to *bowel complaints*, especially in children. The dose for an adult is from half a drachm to a drachm (1·95–3·9 Gm.); for a child two or three years old, from five to ten grains (0·33–0·65 Gm.).

PULVIS SCAMMONII COMPOSITUS. Br. Compound Powder of Scammony.

(PŬL'VIS SCAM-MŌ'NI-Ī CŌM-PŌS'I-TŬS.)

"Scammony Resin, in powder, 4 *ounces* (Imperial) or 100 grammes; Jalap, in powder, 3 *ounces* (Imp.) or 75 grammes; Ginger, in powder, 1 *ounce* (Imp.) or 25 grammes. Mix." *Br.*

This does not appear to us a very eligible preparation. The dose is from ten to twenty grains (0·65–1·3 Gm.).

PULVIS TRAGACANTHÆ COMPOSITUS. Br. Compound Powder of Tragacanth.

(PŬL'VIS TRĂG-Ą-CĂN'THÆ CŌM-PŌS'I-TŬS.)

"Tragacanth, in powder, 1 *ounce* (Imperial) or 25 grammes; Gum Acacia, in powder, 1 *ounce* (Imp.) or 25 grammes; Starch, in powder, 1 *ounce* (Imp.) or 25 grammes; Refined Sugar, in powder, 3 *ounces* (Imp.) or 75 grammes. Mix." *Br.*

This is applicable to the general purposes of the demulcents, but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders. The dose is from thirty grains to a drachm (1·95–3·9 Gm.).

PYRETHRUM. U. S. (Br.) Pyrethrum. [Pellitory.]

(PĪ-RĒ'THRŬM.)

"The root of Anacyclus Pyrethrum (Linné), De Candolle (nat. ord. Compositæ)." *U. S.*
"The dried root of Anacyclus Pyrethrum, De Cand." *Br.*

Pyrethri Radix, *Br.;* Radix Pyrethri Romani; Pellitory of Spain; Pyrèthre (salivaire), *Fr.;* Bertramwurzel, Römische Bertramwurzel, *G.;* Pietro, *It.;* Pelitre, *Sp.*

Anacyclus pyrethrum. De Cand. *Prodrom.* vi. 15.—*Anthemis pyrethrum.* Willd. *Sp. Plant.* iii. 2184; *B. & T.* 151. The root of this plant is perennial, and sends up numerous stems, usually trailing at the base, erect in their upper portion, eight or ten inches high, and termi-

nated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale-green color. The florets of the disk are yellow; the rays white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast of Europe. The root is the part used under the name of pellitory, or *pellitory of Spain*. According to Hayne, the pellitory of commerce is derived from the *Anacyclus officinarum*, a plant cultivated in Thuringia for medical purposes. This remark, however, can apply only to Germany.

Properties. The dried root of *A. pyrethrum** is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown color externally, whitish within, hard and brittle, and sometimes furnished with a few radicles. It is destitute of odor, though, when fresh, of a disagreeable smell. Its taste is peculiar, slight at first, but afterwards acidulous, saline, and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time and excites a copious flow of saliva. It is officially described as "from 5 to 10 Cm. long, and 1 to 2 Cm. thick, somewhat fusiform, nearly simple, annulate above, wrinkled below, externally dark grayish-brown; internally brownish-white; fracture short; bark rather thick, containing two circles of resin-cells, and surrounding the slender wood-bundles and medullary rays, the latter having about four circles of shining resin-cells; inodorous, pungent, and very acrid." *U. S.* The fractured surface shows that the wood is traversed by large medullary rays in which, as well as in the cortex, are numerous dark resin-ducts. Its analysis by Koene gives, in 100 parts, 0·59 of a brown, very acrid substance, of a resinous appearance, and insoluble in caustic potassa; 1·06 of a dark brown, very acrid, fixed oil, soluble in potassa; 0·35 of a yellow acrid oil, also soluble in potassa; traces of tannin; 9·40 parts of gum; inulin; 7·60 parts of potassium sulphate and carbonate, potassium chloride, calcium phosphate and carbonate, alumina, silica, etc., and 19·80 of lignin, besides loss. (See *A. J. P.*, viii. 175.) Buchheim (*Arch. für Exper. Pathol.*, 5, 458) claims to have discovered as the active principle an alkaloid, *pyrethrine*, which, treated with alcoholic potash, splits up like piperin and yields *pyrethric acid*. Schneegans (*Proc. A. P. A.*, 1897, 736) has obtained this pyrethrine in long branched needles united in tufts, melting at 46° C. (114·8° F.), with an extremely burning taste. It is soluble in absolute alcohol, acetone, ether, strong acetic acid, chloroform, and carbon disulphide. It is also dissolved by strong sulphuric acid, yielding a yellow solution, which soon changes to red.

Medical Properties and Uses. Pellitory is a powerful irritant, used almost exclusively as a sialagogue in certain forms of *headache*, *rheumatic* and *neuralgic affections* of the face, *toothache*, etc., or as a local stimulant, in *palsy of the tongue or throat*, and in *relaxation of the uvula*. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. The dose as a masticatory is from thirty grains to a drachm (1·95–3·9 Gm.). Its action upon the general system has not been studied to any extent, but 50 minims of a tincture of it very nearly killed a child three and a half years old. The symptoms were those of gastro-enteritis, followed by convulsions. (*London Practitioner*, Aug. 1876.) An alcoholic extract is sometimes employed by dentists as a local anæsthetic application to *carious teeth*.

PYROGALLOL. U. S. Pyrogallol. [Pyrogallic Acid.]

$C_6H_3(OH)_3$; 125·7. (PĪ-RŌ-GĂL'LŎL.)

"A triatomic phenol obtained chiefly by the dry distillation of gallic acid. Pyrogallic Acid should be kept in dark amber-colored bottles." *U. S.*

Of the three triatomic phenols indicated by theory, this is the best known, phloroglucin and oxyhydroquinone being the other two. It may be prepared synthetically, but is usually obtained as one of the results of the igneous decomposition of gallic acid, and may be obtained by submitting extract of galls to the same treatment as that used for preparing benzoic acid from benzoin, the reaction being $C_7H_6O_5 = C_6H_6O_3 + CO_2$. The vapors of pyrogallic acid rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is properly to regulate the heat, as at a high temperature this acid passes rapidly into metagallic acid, and thus the product is diminished. According to Löwig, it is best prepared by heating gallic acid, previously dried at 100° C. (212° F.), in a glass retort, by means of a zinc chloride bath, to 210° C. (410° F.), when the pure acid sublimes. It is stated by MM.

* *False Pellitory Root.* A root which has been identified by Mr. E. M. Holmes as the product of *Corrigiola telephiifolia* has been offered in the London market as pellitory. It is readily distinguished from the true root by its being softer and more flexible, by its having a distinctly sweetish taste, and especially by the transverse section of the root, which is of a yellowish-white color, with from three to five pale opaque concentric rings, each alternating with a narrower translucent horny ring.

de Luynes and Espandieu that in the ordinary method of obtaining pyrogallic acid much of the acid is lost. According to Pelouze, the proportion of pyrogallic acid produced ought to be very nearly 75 per cent., but the processes in use yield only 25 per cent., the pyrogallic acid itself undergoing rapid decomposition at an elevated temperature. MM. de Luynes and Espandieu have succeeded in preventing this loss by decomposing gallic acid in water under pressure, instead of by dry sublimation. Gallic acid is introduced into a bronze boiler with twice or three times its weight of water; the temperature is raised to a point ranging from 200° C. (392° F.) to 210° C. (410° F.), and maintained at that point for half an hour, when the liquid is allowed to cool. The boiler now contains a slightly colored solution of pyrogallic acid. This is heated with a little pure animal charcoal, filtered, evaporated sufficiently, and set aside to crystallize. The crystalline mass obtained is somewhat colored. To obtain it entirely white, nothing more is necessary than to distil it in a vacuum. The product is quite 75 per cent. The carbonic acid escapes through the joinings of the apparatus, while the watery vapor is retained. (*A. J. P.*, 1866, p. 22.) Another equally satisfactory procedure is that of Thorpe, for details of which see *A. J. P.*, 1881, p. 53, 236.

Pyrogallic acid is officially described as in "light, white, shining laminæ, or fine needles, odorless, and having a bitter taste; acquiring a gray or darker tint on exposure to air and light. Soluble, at 15° C. (59° F.), in 1·7 parts of water, and in 1 part of alcohol; very soluble in boiling water, and in boiling alcohol; also soluble in 1·2 parts of ether. When heated to 131° C. (267·8° F.), Pyrogallol melts, and may be sublimed unchanged. When ignited, it is consumed, leaving no residue. The aqueous solution, which is at first neutral and colorless, gradually acquires, by exposure to the air, a brown color and an acid reaction due to absorption of oxygen. The same change of color takes place very rapidly if the solution contains a caustic alkali. The aqueous solution (1 in 10) of Pyrogallol reduces solutions of the salts of silver, gold, and mercury, even in the cold. When freshly prepared, 1 C.c. of the aqueous solution (1 in 20) is colored brownish-red by a few drops of ferric chloride test-solution, and this color is changed to deep bluish-black on the addition of 1 or 2 drops of ammonia water. A bluish-black color is also produced in the aqueous solution of Pyrogallol by freshly prepared ferrous sulphate test-solution." *U. S.* According to Rosing, of Christiania, it is always partially converted, when sublimed, into metagallic acid, to which probably it owes its acid reaction as generally found in commerce; for when quite pure it has no influence on litmus paper. It is a triatomic phenol, $C_6H_3(OH)_3$, and is therefore, properly speaking, not an acid at all: hence the change in the official title to "Pyrogallol." One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides; and its use in photography is based on this effect exercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in alkaline solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. By the action of phthalic anhydride upon pyrogallol is formed *gallein*, a dye-color much used in calico-printing. By the action of glacial acetic acid upon pyrogallol in the presence of zinc chloride is formed *gallacetophenone*, $CH_3 - CO - C_6H_2(OH)_3$, which has been used in medicine as a substitute for pyrogallol.

Medical Properties and Uses. Led by the resemblance of pyrogallol to phosphorus in its affinity for oxygen, M. J. Personne (*Comptes-Rendus*, Oct. 1869), in a series of experiments, discovered that it produced in dogs symptoms and post-mortem lesions similar to those caused by phosphorus; but its physiological action was especially studied by Prof. Danilevsky (*Lond. Med. Rec.*, Aug. 1887), who found that it produces vomiting, with apathy, fibrillary twitchings, dyspnœa, great fall of temperature, chocolate color of the blood and destruction of red blood-corpuscles, hæmoglobinuria, coma, convulsions, and death by paralysis. A half ounce taken internally by a young man caused after some hours violent burning pains in the stomach, with black vomit, followed by icterus, diarrhœa, methæmoglobinuria, delirium, coma, and death after four days. The liver and spleen were notably swollen. (*Journ. des Praticiens*, May, 1896.)

The experiments made upon frogs prove that the drug has a direct action upon the nerve-centres: indeed, it would seem to influence powerfully the nutrition and function of all the higher tissues. Although Professor Danilevsky found that in doses of from five to ten grains twice a day it causes in man no untoward effects, pyrogallol is not used internally; but it has been largely employed in the treatment of *lupus*, *psoriasis*, and allied affections of the skin. In concentrated form it is a powerful caustic, and when used externally may by its absorption cause general poisoning. There are at least two deaths on record as the result of its external

application. The symptoms were chills followed by malaise and headaches, vomiting, diarrhœa, collapse, with pallid or cyanosed lips and a peculiar greenish hue of the skin, rapid pulse and respiration, a dark-brown or black albuminous urine, diminished reflexes, insomnia, restlessness, and death in coma.

When it is applied in solution or ointment, pyrogallol stains the skin, but not permanently; linen and other clothing are, however, permanently darkened. The remedy is used in the form of ointment or solution, in strength varying from five to fifteen per cent., care being always exercised not to apply it over too large a surface at one time, for fear of absorption. When first applied to a raw surface, or even to the skin, it may produce pronounced pain and severe irritation. Before the use of pyrogallol vaseline is sometimes applied thoroughly and wiped off, to remove scales and other morbid products. Especially to avoid the staining of the clothing, Elliot has proposed a solution of pyrogallol in flexible collodion. This preparation, drying to a film upon the skin, acts therapeutically, but does not stain. The strength of the solution may be from twenty to forty grains to the ounce.

PYROXYLINUM. U. S. (Br.) Pyroxylin. [Soluble Gun Cotton. Colloxylin.]

(PŸ-RŎX-Ŷ-LĪ'NŬM.)

Pyroxylin, *Br.;* Pyroxylon, *U. S.* 1870; Gun Cotton; Fulmicoton soluble, *Fr.;* Collodiumwolle, *G.*

"Purified Cotton, *one hundred grammes* [or 3 ounces av., 231 grains]; Nitric Acid, *fourteen hundred cubic centimeters* [or 47 fluidounces, 163 minims]; Sulphuric Acid, *twenty-two hundred cubic centimeters* [or 74 fluidounces, 187 minims]; Alcohol, Ether, Water, each, *a sufficient quantity.* Mix the Acids gradually in a glass or porcelain vessel, and, when the temperature of the mixture has fallen to 32° C. (90° F.), add the Purified Cotton. By means of a glass rod imbue it thoroughly with the Acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of Water, and subsequently with Alcohol, and pressed, is found to be soluble in a mixture of *one volume* of Alcohol and *three volumes* of Ether. Then remove the Cotton from the Acids, transfer it to a larger vessel, and wash it, first, with cold Water, until the washings cease to have an acid taste, and then with boiling Water, until they cease to redden blue litmus paper. Finally, drain the Pyroxylin on filtering paper, and dry it in small, detached pellets, by means of a water-bath or steam-bath, at a temperature not exceeding 60° C. (140° F.). Keep the Pyroxylin, loosely packed, in well-closed vessels containing not more than about 25 Gm., in a cool and dry place, remote from lights or fire." *U. S.*

"Cotton, 1 *ounce* (Imperial) or 10 grammes; Sulphuric Acid, 5 *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Nitric Acid, 5 *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Acids in a porcelain mortar, immerse the Cotton in the mixture, and after it is thoroughly wetted by the Acids stir it for three minutes with a glass rod; wash the product with Distilled Water until free from acid; drain on filtering paper, and dry the Pyroxylin on a water-bath." *Br.*

Gun cotton was discovered by Schönbein, of Basel, in Switzerland. The name is applied to several closely related yet distinct products. They are not, as was at first supposed, nitro-derivatives in which the group NO_2 merely replaces hydrogen atom for atom, but compounds in which the nitric acid residue NO_3 is present, replacing OH groups of the cellulose formula. Thus, taking the doubled formula $C_{12}H_{20}O_{10}$ for cellulose, there is produced by the action of nitric acid under different circumstances $C_{12}H_{14}O_4(NO_3)_6$, and following this, successively, $C_{12}H_{15}O_5(NO_3)_5$, $C_{12}H_{16}O_6(NO_3)_4$, $C_{12}H_{17}O_7(NO_3)_3$, and $C_{12}H_{18}O_8(NO_3)_2$. The first of these, the hexanitrate, is insoluble in alcohol and ether, and constitutes the true explosive gun cotton. The soluble gun cotton used in the preparation of *collodium* is a varying mixture of the four lower nitrates, but is chiefly made up of the tri- and tetra-nitrates. (Tollens, *Handbuch der Kohlenhydrate,* 1888.) The hexanitrate, when very thoroughly washed free from acid, is insoluble in water, alcohol, ether, and all mixtures of alcohol with ether. It constitutes the true explosive gun cotton, which when compressed in cakes and fired by a fulminate explodes with great violence. Other compounds intermediate between some of these have been described by different chemists, but Abel, the chemist of the Woolwich Arsenal in England, has shown that they were imperfectly purified preparations.

Properties. Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. When intended for solution it is best made by the joint action of sulphuric and nitric acids, or, as proposed by Dr. Ellet, of the South Carolina College, of potassium nitrate and sulphuric acid. Experience has thoroughly shown that the use of the acids as practised in the present official formula gives better results than the employment of potassium nitrate and sulphuric

acid, which was directed in the U. S. P. 1860.* Care should be exercised not to let the mixture attain a temperature much above 32° C. (90° F.). It is insoluble in water, and nearly so in alcohol, but dissolves freely in acetic ether and amyl acetate. (*A. J. P.*, 1887, 275.) "Readily soluble in a mixture of equal volumes of *ether* and *alcohol* (90 per cent.). It leaves no residue after ignition (absence of mineral impurity)." *Br.* M. Guichard proposes the use of chemically pure filtering paper as yielding a superior product to cotton. He takes 1400 parts of sulphuric acid, sp. gr. 1·82; 700 parts of nitric acid, sp. gr. 1·37; 70 parts of the paper; puts the mixed acid in a vessel surrounded by cold water to keep down the temperature, drops the paper in leaf by leaf, allows it to stand three hours, and then washes freely with water. (*Journ. de Pharm.*, 4e sér., xii. 290.) According to Dr. J. H. Gladstone, of England, gun cotton is subject to spontaneous decomposition if kept for some time. The same fact was observed by Mr. James Beatson, of New York, and Prof. Procter, of Philadelphia. The specimen observed by Prof. Procter to undergo decomposition had not been well washed. The change is shown by the bottle in which the gun cotton is kept becoming full of nitrous acid vapor; and the substance is so far altered that it is no longer explosive or soluble in ether. M. Bouet states that the decomposition from exposure to light takes place sooner in gun cotton which has been prepared with potassium nitrate and sulphuric acid than where the mixed acids have been used. He says that, with both, the sides and bottom of the bottle are nearly covered with crystals of oxalic acid. (See *A. J. P.*, March, 1862, p. 187.) According to M. Béchamp, of Strasburg, the product is soluble in ether if the cotton be immersed in a mixture of nitric and sulphuric acid while still hot from their reaction, but not soluble if the cotton be added to the mixture when cold. By treating gun cotton with ferrous chloride, M. Béchamp caused the disengagement of nitrous oxide gas, and gave the filaments a coating of ferric oxide, which was readily dissolved by hydrochloric acid. After this treatment the gun cotton was restored to its original state of cotton. (*Chem. Gaz.*, Jan. 1, 1854, p. 11.) When kindled, gun cotton flashes off like gunpowder, burning without residue. Yet, according to M. Bleekrode, when wet with ether, or similar fluid, and touched with a light, the liquid will burn out of it without firing it. (*Journ. de Pharm.*, 4e sér., xviii.) Its inflaming point is at 187·7° C. (370° F.). Dr. Marx makes it lower. It has been tried as a substitute for gunpowder in fire-arms, etc., but it has not been found useful except for some special purposes. Pyroxylin, or soluble gun cotton, is now extensively used as the basis of transparent varnishes for lacquering metal and wood. The solvent employed is usually a mixture of methyl alcohol or acetone with petroleum benzin, the miscibility of which is effected by the addition of small quantities of compound ethers like amyl acetate.

QUASSIA. U. S. (Br.) Quassia.

(QUÂS'SI-Ą.)

"The wood of Picræna excelsa (Swartz), Lindley (nat. ord. Simarubeæ)." *U. S.* "The wood of the trunk and branches of Picræna excelsa, Lindl." *Br.*

Quassiæ Lignum, *Br.:* Quassia Wood; Bitter Wood; Bitter Ash; Quassie, Bois amer, Bois de Quassie, *Fr.;* Quassienholz, *G.;* Legno della Quassia, *It.;* Leño de Quassia, *Sp.*

The genus Picræna, yielding quassia, is now referred by Engler and Prantl to Picrasma. The genus is represented by eight species, which are found in the warmer regions of the Old and New World. They all possess a bitter wood and bark. The one most esteemed is *Picrasma excelsa* (Sw.) Planch., the wood of which furnishes the Jamaica quassia, which is official. The medicine was formerly obtained from *Quassia amara;* but more than twenty years since Lamarck stated that, in consequence of the scarcity of this tree, *Quassia excelsa* had been resorted to as a substitute, and the Pharmacopœias now acknowledge only the latter plant. The genuine quassia plant, however, of Surinam is the *Q. amara;* and we shall, therefore, give a brief description of both species.

* J. G. Flint states that he has often been unsuccessful with the official formula, and recommends the following as perfectly reliable. Place 6 parts by weight of nitric acid in a stone jar, and pour on it 12 parts by weight of sulphuric acid. When the temperature has fallen to about 35° C., place the jar in a larger vessel, and surround it with broken ice. After the temperature has fallen to 15° C., take 1 part of absorbent cotton, loosen it well, and place a small portion at a time carefully on the surface of the acid and with a clean glass rod press it below the surface. Keep the thermometer in the acid, and watch the temperature closely. If at any time it rises above 16·5° or 17° C., stop the addition of cotton until the temperature has fallen to 15° C. After five hours, remove the jar from the ice, and drain off as much of the acids as possible, pressing the cotton with the glass rod. Protect the hands with rubber gloves, and take up the cotton in small portions, washing each quickly in cold water, moving the cotton about to avoid any rise in the temperature. Finally wring out well, and spread on clean boards to dry. Hot water for the washing must never be used. As to the keeping, the author directs to keep it in an open jar under distilled water. Tightly-closed containers will make trouble. The acids may be used several times over. (*Western Druggist*, 1892.)

Picræna excelsa. Lindley, *Flor. Med.* 208; *B. & T.* 57.—*Quassia excelsa.* Willd. *Sp. Plant.* ii. 569.—*Simaruba excelsa.* De Cand. *Prodrom.* i. 733; Hayne, *Darstell. und Beschreib.*, etc., ix. 16. As its name imports, this is a lofty tree, sometimes attaining the height of not less than one hundred feet, with a straight, smooth, tapering trunk, which is often three feet in diameter near its base, and is covered with a smooth, gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green color, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. The longitudinal section of the wood exhibits elongated cells containing single crystals of calcium oxalate. The transverse section exhibits medullary rays, mostly two or three cells in width. This species inhabits Jamaica and the Caribbean Islands, where it is called *bitter ash.*

Quassia amara. L. *Sp. Pl.* (1762) 553; Willd. *Sp. Plant.* ii. 567; Woodv. *Med. Bot.* 574, t. 204. The bitter quassia is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green color on their upper surface, and paler on the under. The common footstalk is articulated and winged. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. *Quassia amara* is a native of Surinam, and is found in Brazil, Guiana, Colombia, Panama, and the West Indies, as also in some tropical countries of the Old World. Its root, bark, and wood were formerly official. They are excessively bitter, as in fact are all parts of the plant. It is uncertain whether any of the product of this tree now reaches our markets.*

Quassia comes in cylindrical billets of various sizes, from an inch to near a foot in diameter, and several feet in length. These are frequently invested with a light-colored smoothish bark, brittle, and but slightly adherent, and possessing in at least an equal degree the virtues of the wood. Their shape and structure clearly evince that they are derived from the branches or trunk and not from the root of the tree. In commerce they are usually in splinters, chips, or raspings. The wood is "dense, tough, of medium hardness, porous, with a minute pith and narrow, medullary rays, inodorous, and intensely bitter."† *U. S.* It is at first whitish, but becomes yellow by exposure, and sometimes has blackish spots or markings, due to the presence of the mycelium of a fungus. It is inodorous, and has a purely bitter taste, surpassed by that of few other substances in intensity and permanence. It imparts its active properties, with its bitterness and yellow color, to water and alcohol. Its virtues depend upon a peculiar bitter crystallizable principle, denominated *quassin*, which was first discovered by Wiggers, who assigned it the formula $C_{10}H_{12}O_3$. Quassin is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts of which at 54° C. dissolve only 0·45, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neutral, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, the salts of iron, sugar of lead, or even lead subacetate. Adrian and Morcaux (*A. J. P.*, 1884, p. 98) claim to have purified the quassin to a degree beyond that reached by Wiggers and Christiansen, but give no analyses of it.

Oliveri and Denaro (*A. J. P.*, 1885, p. 29) obtained quassin in a thoroughly pure, crystallized state, and made a complete study of it. They give it the formula $C_{32}H_{44}O_{10}$. It melts at 210°–211° C., and is very soluble in alcohol, chloroform, and acetic acid, but only sparingly so in ether. Its aqueous solution becomes yellow on exposure to the air, is dextro-rotatory, excessively bitter, and reduces Fehling's solution. When quassin is heated to 90° C. for some

* According to A. H. Hills, it is possible to distinguish the wood of true quassia from that of Surinam quassia (*Quassia amara*) by the fact that in the former the medullary rays are mostly three cells in width, and the cells are irregular in size but offer regular radial walls in tangential sections, whilst in Surinam quassia the medullary rays are only one cell in width, the cells are nearly uniform in size, and their radial walls wavy in tangential sections.

† *Syrupus Quassiæ.* This syrup is used in the preparation of a harmless fly-poison. Macerate, during twenty-four hours, 1000 parts of quassia wood with 5000 parts of water, then boil for half an hour; set aside for twenty-four hours, and press; mix the liquid with 150 parts of molasses, and evaporate to 200 parts. A weaker decoction of quassia does not kill the flies. From this the *Fly Water* or *Fly Plate* is prepared as follows: Mix when needed, and dispense without filtering, 200 parts of syrup of quassia, 50 parts of alcohol, and 750 parts of water. It is used by moistening with the mixture a cloth or filtering paper on a plate.

hours with dilute sulphuric acid (4 per cent.) it yields *quasside*, $C_{32}H_{42}O_9$, a white, amorphous, bitter substance, formed from quassin by removal of H_2O; no glucose could be detected in the mother-liquors. Bromine forms a derivative which seems to have the formula $C_{32}H_{41}Br_3O_9$. If quassin is heated with concentrated hydrochloric acid in sealed tubes for four hours to 100° C., methyl chloride is formed and a colorless substance deposited, which the authors call *quassic acid*, $C_{28}H_{38}O_6(COOH)_2$. This is far less soluble in alcohol than quassin, and crystallizes in silky needles, which melt at 245° C., and reduce Fehling's solution and ammoniacal silver nitrate in the cold. The authors consider quassin as the methyl ether of this quassic acid, thus: $C_{28}H_{38}O_6(COOCH_3)_2 = C_{32}H_{44}O_{10}$. The real nature of quassin is at present somewhat doubtful, it being probable that distinct substances have been confounded by chemists. Dymock and Warden believe that they have obtained quassin from the wood of *Brucea* or *Picrasma quassioides* of India. According to the researches of Herr Massute (*A. J. P.*, 1890, p. 338), *Quassia amara* contains four principles, which are different from those of *Picræna excelsa*. By shaking an alcoholic extract of quassia wood with chloroform he obtained a mixture of crystals, from which, eventually, four bitter principles, differing in melting point and solubility, were separated. One of these melting at 210°–211° C., and another melting at 239°–242° C., were in too small quantity to be further examined, but the former agreed in melting point and crystalline form with the quassin of Wiggers ($C_{32}H_{40}O_{10}$). Of the other two, one melted at 215°–217° C., and is represented by the formula $C_{35}H_{46}O_{10}$, while the other melted at 221°–226° C., and is represented by $C_{37}H_{50}O_{10}$. From the wood of *Picræna excelsa* two crystalline compounds were separated by Massute, both having lower melting points than either of the quassia compounds. One was in needles, melted at 204° C., and had the composition $C_{35}H_{46}O_{10}$, whilst the other was in prisms, melted at 209°–212° C., and had the composition $C_{36}H_{48}O_{10}$. Both of these are homologues of a third crystalline principle, $C_{29}H_{34}O_{10}$, melting point 212°–216° C., which occurs with them. When the *picrasmin*, $C_{35}H_{46}O_{10}$, above referred to, melting at 204° C., is heated with hydrochloric acid, it is changed like quassin into an acid, which in this case has the formula $C_{33}H_{42}O_{10} + 5H_2O$, and is called *picrasmic acid*. It appears, therefore, that each wood presents a different series of homologous compounds.

Medical Properties and Uses. Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation or increase of animal heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country by a secret remedy, which he was induced to disclose to Mr. Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756, and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is not now in use, having been superseded by the product of *Quassia excelsa*, from the West Indies. Quassia is among the most powerful of the simple bitters, useful in *failure of appetite* due to gastric debility, and in overdoses capable of sufficiently irritating the stomach to produce vomiting. Its active principle, *quassin*, has been studied by Dr. Comparden, who asserts that in moderate doses it acts as a stimulant to the salivary, hepatic, and renal secretions, and in overdoses causes burning pain in the œsophagus, headache, nausea, vertigo, vomiting, diarrhœa, and muscular cramps. It is also stated that if given in doses of six-tenths of a grain (0·04 Gm.) before meals it increases markedly the alvine discharges, and that it is especially useful in *constipation* from debility of the muscular and intestinal coats. The average dose of the pure or crystallized principle is set down as three-tenths of a grain (0·02 Gm.).

Quassia is given in infusion, tincture, or extract, in doses respectively of one-half to one fluidounce (15–30 C.c.), one-half to one fluidrachm (1·9–3·75 C.c.), and one-half to one grain (0·03–0·065 Gm.). Some *dyspeptic* patients who have become habituated to its bitterness, chew the wood occasionally with benefit.

QUERCUS ALBA. U. S. White Oak.

(QUĔR'CUS ĂL'BA.)

"The bark of Quercus alba, Linné (nat. ord. Cupuliferæ)." *U. S.*

Ecorce de Chêne, *Fr.;* Eichenrinde, *G.;* Corteccia della Quercia, *It.;* Corteza de Roble, *Sp.*

This genus comprises numerous species, of which about fifty grow within the limits of the United States. Many of these are applied to important practical purposes. In the Northern hemisphere the oak is among the most valuable and the most widely diffused of all forest

trees. Notwithstanding the great number of species, few, comparatively, have found a place in the official catalogues. *Quercus robur*, or European oak, has a very wide distribution. It is the common British oak, constitutes a large part of the European forests, and has spread itself over almost the whole northern section of Asia and along the northern coast of Africa. There are two distinct varieties of it, one, *pedunculata*, with sessile or shortly stalked leaves and the acorns on long peduncles; the other, *sessiflora*, with the leaf-stalks more or less elongated and the acorns either sessile or provided with a very short peduncle. At the late revision of the Br. Ph. the dried bark of the smaller branches and young stems of this tree, QUERCUS CORTEX, Br. 1885, was dismissed from the official list. Our own Pharmacopœia recognizes only *Q. alba*, or white oak. *Q. tinctoria*, or *black oak*, which was formerly official, and various other species, afford actively astringent barks. Such are *Q. falcata*, or *Spanish oak*, *Q. prinus*, or *white chestnut oak*, and *Q. montana*, or *rock chestnut oak*.

1. *Quercus alba.* L. *Sp. Pl.* (1753) 996; Willd. *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylva*, i. 17; *B. & T.* 250. Of all the American species, the *white oak* approaches nearest, in the character of its foliage and the properties of its wood and bark, to *Q. pedunculata* of Great Britain. When allowed to expand freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favorable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch long.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, except the *live oak* (*Q. virens*), which is preferred in ship-building. The bark is sometimes used for tanning, but the barks of the *red* and *Spanish oaks* are preferred. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark.

White-oak bark, deprived of its epidermis, is of a light-brown color, of a coarse, fibrous texture, and not easily pulverized. It is officially described as "in nearly flat pieces, deprived of the corky layer, about 5 Mm. thick; pale brown; inner surface with short, sharp, longitudinal ridges; tough; of a coarse, fibrous fracture, a faint, tan-like odor, and a strongly astringent taste. As met with in commerce it is usually an irregularly coarse, fibrous powder, which does not tinge the saliva yellow." *U. S.* The English oak bark was formerly officially described as occurring "in quills covered with a smooth shining silvery or ash-gray variegated with brown corky layer; internally cinnamon-brown or brownish-red and longitudinally striated; fracture tough and fibrous; taste very astringent; no marked odor." Water and alcohol extract the active properties of oak bark. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medical virtues, as well as its use in the preparation of leather, chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark; and the English oak is said to yield four times as much in spring as in winter. Sir H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive.

The tannic acid of the oak barks is known as *quercitannic acid*, and has, according to Löwe (*Zeitsch. Anal. Chem.*, 20, p. 208), two forms, one soluble in water, of the formula $C_{28}H_{28}O_{14}$, and the other difficultly soluble, $C_{28}H_{24}O_{12}$. Both are changed by the loss of water into *oak red*, $C_{28}H_{22}O_{11}$. Neither is a glucoside.

Gerber discovered in European oak bark a peculiar bitter principle upon which he conferred the name of *quercin*. It is obtained by boiling the bark with water acidulated with one hundredth of sulphuric acid, adding first milk of lime until the sulphuric acid is removed, and then a solution of potassium carbonate so long as a white precipitate is produced, filtering the liquor, evaporating to the consistence of a thin extract, adding alcohol, and finally evaporating the spirituous solution down to a small volume, and allowing it to rest for some days. Yellow crystals form, which may be obtained colorless by repeated crystallizations. This quercin Husemann considers to have been only impure quercite (or oak sugar).

2. *Quercus tinctoria*, or *black oak*, is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark-brown color. The leaves are ovate-oblong, pubescent, slightly sinuated, with oblong, obtuse, mucronate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black-oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a coloring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow color, which is deepened by alkalies and rendered brighter by acids. Under the name of *quercitron*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow color. The coloring principle is called *quercitrin*, and the formula $C_{36}H_{38}O_{30}$ given to it by Liebermann and Hamburger. Herzig (*Journ. Chem. Soc.*, 1893, 413), however, has found that its composition is more correctly expressed by the formula $C_{21}H_{22}O_{12} + 2H_2O$, and in this he is confirmed by Rudolph (*Pharm. Post*, 1893, 529). The reaction for its decomposition is $C_{21}H_{22}O_{12} + H_2O = C_{15}H_{10}O_7 + C_6H_{10}O_6$, the products being *quercetin* and *isodulcite* in equal molecules.

Quercitrin forms yellowish crystals, which, pulverized, yield a citron-yellow powder. It is neutral in reaction, is odorless, and in the dry condition tasteless, but in hot aqueous or alcoholic solution has a bitter taste. It fuses at 160° to 200° C. to a resinous mass. It is almost insoluble in cold water, sparingly soluble in hot water, and easily soluble in alcohol and alkaline solution.* Besides this principle, the bark contains much *quercitannic acid;* but it is less used in tanning than the other barks, in consequence of the color which it imparts to the leather, and it was dropped from the U. S. P. 1890 on account of its decoction staining so decidedly.

Medical Properties and Uses. Oak bark is astringent and somewhat tonic; but it is not employed as an internal remedy. On account of its cheapness it is much used externally. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable and the stomach is not disposed to receive medicines kindly. It has been employed in this way in *marasmus*, *scrofula*, *intermittent fevers*, *chronic diarrhœa*, and *cholera infantum*. As an injection in *leucorrhœa*, a wash in *prolapsus ani* and *hemorrhoidal affections*, and a gargle in *prolapsed uvula*, the decoction is often useful, and the infusion obtained from tanners' vats has been employed beneficially as a wash for *flabby, ill-conditioned ulcers.*

QUILLAJA. U. S. (Br.) Quillaja. [Quillaia, Pharm. 1880. Soap Bark.]

(QUĬL-LĀ-JĄ—kwil-lā′yą.)

"The inner bark of Quillaja Saponaria, Molina (nat. ord. Rosaceæ)." *U. S.* "The inner part of the bark of Quillaja saponaria, Molina." *Br.*

Quillaiæ Cortex, *Br.*, Quillaia Bark; Panama Bark; Ecorce de Quillaya, *Fr.;* Seifenrinde, *G.;* Quillay, *Chilian.*

The name of this genus is said to be derived from the popular name of the tree *Quillay*, which in turn comes from the Chilian word *quillean*, to wash.

Quillaja saponaria, Molina. This is a tree of moderate size, with alternate oval or oblong leaves, with entire or slightly denticulate margins. Male and female flowers grow on the same branch, are axillary, pedunculate, and without corolla. The calyx of the female flower persists in fruit, and has its limb deeply divided into five oval acute segments. The bark is thick, the wood very hard.† The tree is a native of Peru and Chili, but is now cultivated in Northern Hindostan, where it is said to resist well the frosts of winter, and to be flourishing.

Properties. Soap bark is officially described as in "flat, large pieces, about 5 Mm. [$\frac{1}{5}$ inch]

* Quercitrin has been found also in various other plants, as in the leaves of *Ruta graveolens*, and the flower-buds of *Capparis spinosa*, *Sophora japonica*, and *Æsculus hippocastanum*, or horse-chestnut. (*Chem. Gaz.*, May 2, 1859, p. 161.) As this principle is capable of assuming various colors under various chemical influences, the idea has been advanced that it might be the coloring principle of flowers. (*A. J. P.*, 1860, 222.)

Acorns, besides the bitter and astringent principles of the bark, contain a peculiar saccharine matter (*quercite*), which is insusceptible of the vinous fermentation. (*Journ. de Pharm.*, 3e sér., xx. 335.) They are sometimes used as a tonic or astringent; and a decoction made from roasted acorns has been long employed in Germany as a remedy in scrofula. Before roasting they should be deprived of their shells; and the cotyledons, according to Dausse, should lose, during the process, 140 parts of their weight out of 500. (*Pharm. Centralbl.*, Oct. 9, 1850, p. 687.) From half an ounce to an ounce may be prepared and taken like coffee at breakfast. (*Richter.*)

† This tree was first described by the famous Abbé Giovanni Ignazio Molina in the *Saggio sulla Storia naturale del Chili*, published at Bologna, in 1782; second edition, 1810. (Translated into German, I. D. Brandis, Leipsic, 1786; into French, M. Gruvel, Paris, 1789; into English, London, 1809; also Middletown, Conn., 1880.) It is first noticed by systematic writers in the second (Gmelin's) edition of the *Syst. Nat.*, tome ii. p. 767.

thick; outer surface brownish-white, often with small patches of brown cork attached, otherwise smooth; inner surface whitish, smooth; fracture splintery, checkered with pale brownish bast-fibres imbedded in white tissue; inodorous; taste persistently acrid; the dust very sternutatory." *U. S.* The fracture exhibits, when slightly magnified, glistening prismatic crystals. A transverse section is marked with fine radial and tangential lines. When bruised and macerated in water, it imparts to that liquid the property of frothing like soap, when agitated. This has been found by MM. Fleury, Jr., and Boutron-Chalard to be owing to the existence of *saponin* in the bark, the same principle as that which gives a similar property to *Saponaria officinalis*. (See PART II.) The bark contains neither tannic acid nor any bitter principle. The formula of saponin, given by Rochleder, was $C_{32}H_{54}O_{18}$, and Schiaparelli agreed with him. Stütz, however (*Ann. Ch. und Pharm.*, 218, 231), gives it as $C_{19}H_{30}O_{10}$, and this is now accepted for the saponin of quillaja bark. Saponin is slowly decomposed by dilute acids into *sapogenin*, $C_{14}H_{22}O_2$, and a glucose. R. Kobert (*Chem. Central.*, 1893, i. 32) gives a list of one hundred and forty plants which contain bodies of the saponin class. He arranges them under several formulas which seem to form an homologous series. Thus, $C_{17}H_{26}O_{10}$ he terms Saponin I. (*senegin* or *quillaia sapotoxin*); $C_{18}H_{28}O_{10}$ is Saponin II. (Schmiedeberg's *digitonin* or *saporubrin*); $C_{19}H_{30}O_{10}$ is Saponin III. (*quillain* or *quillaiac acid*); $C_{20}H_{32}O_{10}$ is *cyclamin*, Paschki's *digitoxin*, or *sarsaparill-saponin*; $C_{22}H_{36}O_{10}$ is *sarsa-saponin*; $C_{26}H_{44}O_{10}$ is *parillin*.

Saponin, as found in commerce, is a powerful poison. Kobert states, however, that *pure* saponin, $C_{19}H_{30}O_{10}$, is destitute of physiological action, and that commercial saponin depends for its activity mainly upon *quillaiac acid* and *sapotoxin*, the other substances present being saponin and *lactosin*, $C_{36}H_{62}O_{31}$.

Medical Properties. Both the active principles, quillaiac acid and sapotoxin, of quillaia bark are violent local irritants. In a case of poisoning by quillaiac acid (*Therap. Gaz.*, xi.) the symptoms were violent vomiting, with epigastric pain, increased diuresis and cystic irritation, accompanied by cold sweats, feeble pulse, threatened syncope, and other evidences of collapse.

Sapotoxin, when in sufficient concentration and amount, is a fatal poison to all forms of protoplasm. Given to the lower animals in very large toxic dose it produces violent convulsions with death from failure of the respiration. When in smaller quantities it causes violent dysenteric diarrhœa, with ecchymotic hyperæmia, œdema, and necrotic destruction of the intestinal mucous membrane. The smallest lethal doses are said to produce great weakness, death occurring after some days through collapse and general paralysis without intestinal symptoms. In such cases, when the drug is administered hypodermically, a severe hemorrhagic inflammation occurs at the place of injection. Fatty preparations of sapotoxin applied to the sound skin produce redness and burning with, after repeated applications, painful pustulation. Both sapotoxin and quillaiac acid have the power of breaking down the red blood-corpuscles, but it is not apparent that such destruction plays an important *rôle* in poisoning by these substances except at the point of injection after hypodermic use.

On account of the active principles of soap bark being the same as those of senega, and to some extent of sarsaparilla, Prof. Kobert has proposed the use of quillaja as a cheap substitute for these much-used drugs. As a stimulating expectorant he uses a decoction (five parts to two hundred) in doses of a tablespoonful for the adult. As a substitute for syrup of senega Prof. Power suggests the *syrup of quillaja*, prepared by adding four parts of the fluid extract (made by the process for fluid extract of arnica root, see p. 540) to sufficient syrup to make twenty-five parts. (*P. J. Tr.*, Oct., 1886.)

Quillaja is much used in the arts for washing silk, cloth, and other fabrics, for which soap would not be suitable. It is an emulsifying agent, but unless ordered by the physician should never be used by the pharmacist in the preparation of emulsions, on account of its active medical properties.

QUINIDINÆ SULPHAS. U. S. Quinidine Sulphate.

(QUĬN-Ĭ-DĪ'NÆ SŬL'PHĂS.)

$(C_{20}H_{24}N_2O_2)_2H_2SO_4.2H_2O$; 780·42. $(C_{20}H_{24}N_2O_2)_2H_2SO_4.2H_2O$; 782.

"The neutral sulphate of an alkaloid obtained from the bark of several species of Cinchona (nat. ord. Rubiaceæ). Quinidine Sulphate should be kept in well-stoppered bottles, in a dark place." *U. S.*

The alkaloid which forms the base of this salt is quinidine, which is isomeric with quinine, having the composition $C_{20}H_{24}N_2O_2$. Quinidine was discovered in 1833 by MM. O. Henry and Delondre, but they afterwards concluded that it was quinine hydrate, as it had the same com-

position as quinine. Winckler, in 1844, announced anew the existence of the same alkaloid, which he considered distinct, and named it "*chinidine*;" this substance was not pure, and Pasteur, in 1853, proved that it really consisted of two alkaloids, one of which he called *cinchonidine*, and the other *quinidine*. This view is now generally accepted, although Hesse insists on calling quinidine "*conchinine*;" but the latter name is used to only a limited extent in Germany, and scarcely at all elsewhere.

Quinidine crystallizes from alcohol with $2\frac{1}{2}H_2O$ in large lustrous monoclinic prisms or needles, efflorescent in the air; from ether permanent rhombohedra with $2H_2O$ are obtained; from boiling water permanent plates with $1\frac{1}{2}H_2O$. (*Hesse.*) It effloresces on exposure to the air. It is sublimable by heat without change, and is condensed in a crystalline form. It resembles quinine not only in composition, but also in its chemical relations with chlorine and ammonia, being rendered green by the successive action of those agents. According to Dr. Herapath, it resembles it also in causing a fluorescent appearance when dissolved in water, which is not the case with either cinchonine or cinchonidine, or is so, at least, in a much less degree. It differs, however, in its greater facility of crystallization, in its much less solubility in ether, and in its influence on polarized light, quinidine producing deviation to the right, and quinine to the left. De Vrij states, as the result of his observation, that quinidine forms a salt of very difficult solubility with hydriodic acid, and that, consequently, when a solution of potassium iodide is added to a solution of quinidine sulphate a white precipitate takes place. By this test quinidine may be distinguished from the other cinchona alkaloids, and detected when mixed with them in solution, no other yielding a precipitate with potassium iodide. (See *A. J. P.*, xxix. 233.) Dr. Herapath proposes another test to distinguish this alkaloid from quinine. If to a solution of quinine sulphate in acetic acid, tincture of iodine be added, and the mixture heated and then allowed to cool, a beautiful emerald-green compound is formed; whilst quinidine sulphate treated in the same way yields a brown precipitate. When the mixture of this alkaloid with cinchonidine is exposed to hot air, the crystals of quinidine effloresce, and may be distinguished from the others by their opaque whiteness. Vreven (*Chem. and Drug.*, March 5, 1898, 400) states that the crystals yielded by Marmé's reagent (potassio-cadmium iodide) with quinidine are different from those obtained from any of the other cinchona alkaloids. They are seen under the microscope to consist of bushes of fine needle-like crystals quite different from those of quinine, cinchonine, and cinchonidine.

Commercial quinidine, consisting generally of quinidine with a much larger proportion of cinchonidine, and sometimes, there is reason to believe, exclusively, or nearly so, of the latter alkaloid, was carefully examined by H. G. Leers. It readily crystallizes from its alcoholic solution, by spontaneous evaporation in hard, shining, colorless crystals, which are easily pulverized and yield a snow-white powder. They melt without decomposition or loss of water at 175° C. (347° F.), and on cooling concrete into a grayish-white crystalline mass. At a higher heat they take fire, and burn with an odor resembling that of the volatile oil of bitter almond. Their taste is bitter, but less intensely so than that of quinine. Quinidine is soluble, according to Hesse, in 2000 parts of water at 15° C.; in 750 parts of boiling water; in 26 parts of 80-per-cent. alcohol at 20° C.; in 22 parts of ether of sp. gr. 0·729 at 20° C., or in 35 parts of the same at 10° C. (*Hesse*, 1868); according to Dragendorff, in 76·4 parts of ether at 10° C.; but the solubilities of commercial quinidine vary more or less according to the relative quantities of quinidine proper and cinchonidine contained in it. With the acids it forms salts, most of which are beautifully crystallizable, and much more soluble than those of quinine. There are, as of quinine and cinchonine, two sets of the salts of quinidine, which may be considered either as neutral and acid or as basic and neutral. It differs from quinine by its much slighter solubility in ether. From the aqueous solution of its salts the alkalies and their carbonates and bicarbonates throw down pulverulent precipitates not soluble in an excess of the precipitant. With sodium phosphate, silver nitrate, and mercuric chloride it forms white, with gold terchloride light yellow, and with platinic chloride orange-yellow precipitates. It may be obtained by first precipitating it from the solution of one of its salts by an alkali, and then repeatedly dissolving in alcohol and crystallizing, until it is entirely freed from a greenish-yellow resinous substance which is apt to attend it. From quinine it may be separated by repeated washing with ether, until the ethereal solution no longer affords evidence of the presence of quinine by the test of chlorine water and ammonia.

Properties. Quinidine sulphate is, according to one view, neutral, consisting of one mol. each of quinidine, sulphuric acid, and water; according to another, basic, containing two mols. of base, one of acid, and one of water, and therefore a disulphate. It is obtained from the

quinidine barks by the same process as that by which quinine sulphate is procured from the quinine-yielding barks. When the two alkaloids are contained in the same bark, the quinidine sulphate (commercial) remains in the mother-waters in consequence of its greater solubility. By the addition to its solution of a quantity of sulphuric acid equal to that which it contains, it is converted into the bisulphate (sulphate on the basic view), crystallizable in fine acicular crystals like asbestos, and possessing the formula $C_{20}H_{24}N_2O_2H_2SO_4 + 4H_2O$. Quinidine sulphate is officially described as in "white, silky needles, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 8 parts of alcohol; in 7 parts of boiling water, and very soluble in boiling alcohol; also in 14 parts of chloroform, and in acidulated water; almost insoluble in ether. When heated to 120° C. (248° F.), the salt loses its water of crystallization (4·6 per cent.). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution of the salt, when acidulated with sulphuric acid, has a decided, blue fluorescence. On treating 10 C.c. of an aqueous solution (about 1 in 1600) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate. A cold, saturated aqueous solution of the salt yields a white precipitate with potassium iodide test-solution (difference from *quinine sulphate*). An aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid. Quinidine Sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If a small quantity of ammonia water be added to 3 C.c. of an aqueous solution of the salt saturated at 15° C. (59° F.), a white precipitate (quinidine) will be produced, which requires more than 30 C.c. of ammonia or more than 30 times its weight of ether to dissolve it (absence of more than small proportions of *other cinchona alkaloids*)." *U. S.*

Medical Properties. The action of quinidine sulphate upon the system appears to be identical with that of quinine, except in being less powerful. It has been asserted to produce less cerebral and stomachic disturbance, but this statement is probably incorrect for equivalent doses. The exact relation of it in strength to quinine is not thoroughly determined, but the proportion seems to be very nearly that of 3 to 2. Antiperiodic dose, from twenty to sixty grains (1·3–3·9 Gm.).

QUININA. U. S. Quinine.

$C_{20}H_{24}N_2O_2.3H_2O$; 377.22. (QUĪ-NĪ'NĄ.) $C_{20}H_{12}NO_2.3HO$; 189.

"An alkaloid obtained from the bark of various species of Cinchona (nat. ord. Rubiaceæ). Quinine should be kept in well-stoppered bottles, in a dark place." *U. S.*

This alkaloid is prepared by adding to the solution of the sulphate a quantity of ammonia water or solution of soda just sufficient to precipitate the alkaloid.

Properties. Quinine is whitish, rather flocculent, and not crystalline; but it may with care be crystallized from its alcoholic solution in silky needles; and Liebig obtained it from a somewhat ammoniacal aqueous solution in the same form. It is inodorous and very bitter. The crystals obtained from alcoholic solution have the composition $C_{20}H_{24}N_2O_2 + 3H_2O$, and fuse at 57° C. (134·6° F.). They may be deprived of water by warming or exposure over oil of vitriol, and they then fuse at 171·2°–172° C. (340°–341·6° F.). By carefully regulated heat, it may be sublimed unchanged, assuming a crystalline form. (Waddington, *P. J. Tr.*, March, 1868, p. 413.) According to Hesse, anhydrous crystalline quinine is soluble in 1960 parts of water at 15° C. (59° F.), and the trihydrate in 1670 parts. It is soluble in about 900 parts of boiling water, in about 6 parts of cold and in 2 parts of boiling alcohol, very soluble in ether, chloroform, benzene, benzin, carbon disulphide, fixed and volatile oils, and in about 200 parts of glycerin. The alcoholic solution is intensely bitter. Quinine is unalterable in the air. It forms salts with the acids which readily crystallize. The tannate, tartrate, and oxalate are said to be insoluble or nearly so, but are dissolved by an excess of acid. The acetate is so slightly soluble that it is precipitated from a solution of the sulphate by magnesium acetates and the other acetates. (*A. J. P.*, xxx. 386.) When recently precipitated quinine, diffused in water, is exposed to the action of a stream of carbonic acid gas, the quinine is dissolved; and, if the solution be exposed, acicular crystals of quinine carbonate will be deposited, which effloresce in the air, are soluble in alcohol, but insoluble in ether, have an alkaline reaction, and effer-

vesce with acids. After the deposition of the crystals has ceased, the solution yields quinine on evaporation. (Langlois, *Comptes-Rendus*, Nov. 7, 1853, 727.) Freshly precipitated quinine is scarcely soluble to an appreciable extent in an excess of potassa, but is more readily dissolved by ammonia. (Wadgymar, *A. J. P.*, Sept. 1866, 451.) Prof. Flückiger (1878) noticed that solutions of quinine exposed to sunlight rapidly turned brownish yellow, and subsequently deposited a flocculent precipitate, which he proved to be neither quinine nor quinicine, but an entirely different substance. It lost the alkaloidal character, yet possessed the same chemical composition as quinine. He named it *quiniretin*. (*P. J. Tr.*, May, 1878.)

Quinine and its salts may be distinguished from all other alkaloids and their salts, except only quinidine and quinicine, by the beautiful emerald-green color (*thalleioquin*) which results when their solution is treated first with solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. The statement which has been frequently made that the chlorine water must be fresh, was disproved by C. F. Zeller. (See *A. J. P.*, 1880, p. 385.) The least quantity of quinine may be detected by powdering the substance supposed to contain it, then shaking it with ether, and adding successively the tests just mentioned. Its salts are precipitated by mercuric and platinic chlorides, and of a buff color by auric chloride. Quinine in solution turns the plane of polarization to the left, to varying degrees, however, according to the concentration, the solvent used, etc. Acids increase the amount of deviation. In relation to the property possessed by quinine of imparting fluorescence to its aqueous solution, which is possessed also, though in less degree, by other cinchona alkaloids, and other properties common to both quinine and its sulphate, there will be occasion to speak under quinine sulphate. A singular discovery was made by Dr. Bence Jones, of London, of a substance normally present in the animal system having analogous properties, and named by him "*animal quinoidine*."

Quinine is officially described as "a white, flaky, amorphous or crystalline powder, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 1670 parts of water, and in 6 parts of alcohol; in 760 parts of boiling water, and in 2 parts of boiling alcohol; in 23 parts of ether, 5 parts of chloroform, and 200 parts of glycerin; also soluble in carbon disulphide, benzin, benzol, ammonia water, and diluted acids. When heated to about 57° C. (134.6° F.), it melts; at 100° C. (212° F.), it loses about 9 per cent. (or about 2 molecules) of its water of crystallization, the remainder being expelled at 125° C. (257° F.). The anhydrous alkaloid, when pure, melts at 173° C. (343·4° F.). Upon ignition, it is consumed, leaving no residue. Quinine has an alkaline reaction upon litmus paper. A solution of Quinine in diluted sulphuric acid has a vivid, blue fluorescence. On treating 10 C.c. of an aqueous, acidulated solution (about 1 in 1500) of quinine with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate. Quinine should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If 2 Gm. of quinine be mixed, in a small mortar, with 1 Gm. of ammonium sulphate and 10 C.c. of distilled water, the mixture thoroughly dried on a water-bath, the residue (which should be strictly neutral to test-paper) agitated with 20 C.c. of water, then allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, and filtered through a pellet of glass-wool, 5 C.c. of the filtrate, transferred to a test-tube, and gently mixed, without shaking, with 7 C.c. of ammonia water (specific gravity 0·960), should produce a clear liquid. If the temperature during the maceration has been 16° C. (60·8° F.), 7·5 C.c. of ammonia water may be added; if 17° C. (62·8° F.), 8 C.c. (In each case, a clear liquid indicates the absence of more than small proportions of *other cinchona alkaloids*.)" *U. S.*

Quinicine (quinicia). When quinine and cinchonine, or quinidine and cinchonidine, or their salts, are exposed to heat, they are changed into other but isomeric alkaloids,—quinine and quinidine into *quinicine*, isomeric with themselves, and cinchonine and cinchonidine into *cinchonicine*, isomeric with its own antecedents. These new alkaloids are, therefore, products rather than educts, and generally result, in greater or less proportion, from the processes employed in extracting the other alkaloids from bark; though it is not impossible that they may pre-exist in bark to a certain extent, being formed by a natural process, from the same original alkaloids, either in the living tree, or in the barks while drying, after separation from the tree. *Quinicine* is almost insoluble in water, but very soluble in alcohol, and differs from quinine in being dextro-rotatory and uncrystallizable. *Cinchonicine* is also insoluble in water and

soluble in alcohol. It agrees with cinchonine, from which it is derived, in producing deviation of the plane of polarization to the right; but differs from cinchonidine in this respect, and differs from both of these alkaloids in being amorphous or uncrystallizable.

The study of the decomposition products of quinine and associated alkaloids so actively carried on for several years past has thrown considerable light upon its composition. It appears to be a derivative of a partially hydrogenized diquinoline, corresponding to the formula $C_9H_6(OCH_3)N - C_9H_{11}(OH)N.CH_3$. By oxidation with chromic acid it yields *quininic acid*, $C_9H_5(OCH_3)N.COOH$, which is the phenol ester of cinchoninic acid, $C_9H_6N.COOH$; by oxidation with nitric acid it yields *cinchomeronic acid*, $C_5H_3N(COOH)_2$; by the action of fused caustic potash it yields *methoxyquinoline*, $C_9H_6N(OCH_3)$. For a summary of our knowledge upon the constitution of quinine and cinchonine, see *Guareschi's Einführung in das Studium der Alkaloide*, translated by Dr. H. Hermann Kunz-Krause, Berlin, 1896, 524 *et seq.*

The most important artificial salt of quinine is the *sulphate*, the process for procuring which, as well as its properties, will be hereafter described. The *bisulphate*, *hydrobromate*, *hydrochlorate*, and *valerianate* have been introduced into the U. S. Pharmacopœia, and the *iron and quinine citrate* both into this and the British, which give processes for its preparation. The *phosphate*, *acetate*, *citrate*, *lactate*, *camphorate*, *ferrocyanate*, *tannate*, *arsenite*, *antimonate*, *urate*, *hypophosphite*, *chlorate*, *hydrochlorate with urea*, *citro-thymate*, *sulphovinate*, *salicylate*, *sulphosalicylate*, and *meconate*, have also been employed or recommended; but none of them has yet gained admittance into the Pharmacopœias, and none probably is superior to the official sulphate.* The first four may be prepared by saturating a solution of the acids respectively with quinine, and evaporating the solutions. The *camphorate* is recommended as a substitute for the valerianate. (*A. J. P.*, July, 1865, p. 254.) The *ferrocyanate* is directed to be made by boiling together four parts of quinine sulphate and one of potassium ferrocyanide, both in concentrated solutions, pouring off the liquor from a greenish-yellow substance of an oily consistence which is precipitated, washing the latter with distilled water, then dissolving it in strong alcohol at 37·7° C. (100° F.), filtering immediately, and afterwards evaporating the solution. M. Pelouze believes this preparation to be pure quinine, mixed with a little Prussian blue. (*Archives Gén.*, 3e sér., xv. 236.) The *tannate* may be prepared by precipitating one part of quinine sulphate, dissolved in thirty parts of water acidulated with a few drops of sulphuric acid, with a solution of three parts of tannic acid dissolved in thirty parts of cold water, and then washing and drying the precipitate. For other methods of preparing the tannate, see *West. Drug.*, 1893, 362; *Pharm. Centralh.*, 1894, 155; *Proc. A. P. A.*, 1894, 675. It has the advantage of possessing little taste, but doubts have been repeatedly expressed about its efficiency. At best, it is a feeble preparation, not containing more than 32 per cent. of quinine. Either of these salts may be

* *Percentage of Quinine in its Different Salts.* According to Tanret, the salts of quinine in common use contain the following proportions of the alkaloid: acetate, 87·34 per cent.; hydrate (quinine precipitated and dried), 85·70; basic hydrochlorate, 81·60; lactate, 78·26; basic hydrobromate, 76·60; valerianate, 76·05; basic sulphate (the ordinary sulphate), 74·30; sulphovinate, 72·00; neutral hydrobromate, 60·00; neutral sulphate (or acid sulphate), 57·24; tannate, 20·60. The following table was compiled by Dr. Boymond, of Paris:

Salts.	Percentage of			1 part soluble in water at 15° C.	1 part of water dissolves		1 part anhydrous quinine contained in
	Alkaloid.	Acid.	Water of crystallization.		Salt	Anhydrous quinine	
Hydrate	85·72	. . . .	14·28	16·70	0·00059	0·00050	1·16

Tannate	22·60	67·36	10·04	800	0·0012	0·00028	4·42

given in the same dose as the sulphate. *Quinine arsenite* has been recommended by Dr. Ringdon, especially in chronic cutaneous affections. Adler prepares it by dissolving arsenous acid in water, with enough alkali to make the solution neutral, adding about five times its weight of silver nitrate, washing the precipitated silver arsenite, drying, and mixing with three times its weight of quinine hydrochlorate, digesting the mixture for a day with 70-per-cent. alcohol, filtering, and allowing the filtrate to evaporate spontaneously. The salt is crystalline, soluble in alcohol, chloroform, and ether, but sparingly so in water. The dose is one-third of a grain (0·02 Gm.), given at first twice a day, and afterwards three or four times a day. *Quinine antimonate* has been recommended by Dr. La Camera, of Naples, as a febrifuge, being especially applicable to cases of doubtful periodicity. It unites, he thinks, the evacuant properties of the antimonials with the antiperiodic property of quinine. The dose is two or three grains (0·13 or 0·20 Gm.), four times a day. (*Journ. de Pharm.*, 3e sér., xxv. 471.) *Quinine urate* is thought by Dr. Pérayre, of Bordeaux, to be peculiarly efficacious in obstinate intermittents. It is prepared by boiling 10 parts of crude quinine in water, adding gradually 20 parts of crystallized uric acid, and, after sufficient ebullition, filtering and evaporating. A yellow salt is obtained, sometimes amorphous, more frequently crystalline, soluble in hot and less so in cold water, and, according to the author, capable of curing intermittent fever in smaller doses than the sulphate, with less cerebral disturbance, less bitterness, and easier tolerance by the stomach. (*Journ. de Pharm.*, 3e sér., xxxvii. 139.) *Quinine hypophosphite* may be prepared by dissolving 3 parts of calcium hypophosphite in 60 parts of distilled water, and adding the filtered solution to a solution of 13 parts of quinine sulphate in 200 parts of alcohol, allowing the mixture to stand two hours, and filtering, distilling off the alcohol and evaporating the solution and setting aside to crystallize. The salt is soluble in 25 parts of cold water, in 1·5 parts of boiling water, and in 10 parts of alcohol. *Quinine glycerophosphate* exists in two conditions, basic and neutral. The basic salt, which is stable, may be made by dissolving 75·6 Gm. of quinine in 500 C.c. of ether and mixing with a solution of 17·2 Gm. of glycerophosphoric acid in 60 Gm. of alcohol (95 per cent.), collecting the white precipitate, washing with ether, and drying. (E. Fallieres, *P. J. Tr.*, 1898, 410.)

Quinine and urea hydrochlorate,—"*chininum bimuriaticum carbamidatum*,"—discovered by Kutais (1878), is best prepared by Rice's process. 79 parts of quinine hydrochlorate are dissolved in 70 parts of hydrochloric acid (sp. gr. 1·050), the solution filtered, 12 parts of urea added, and the whole warmed until the liquid is clear. It is then set aside, that crystals may form. These are soluble in an equal weight of water, and also in strong alcohol. This salt has been recommended especially for hypodermic uses. *Quinine citrothymate* is prepared by Pavesi by heating in a flask on a water-bath 4 parts of quinine and 6 parts of oil of thyme, with enough alcohol to dissolve both. After standing 12 hours, 2 parts of powdered citric acid are added, and the whole heated, filtered, evaporated to a syrup, and allowed to crystallize.*

* *Extemporaneous Preparation of Various Quinine Salts.—Quinine Carbolate.* Quinine, pure, 10 parts; carbolic acid, 5 parts.

Quinine Citrate. Quinine, pure, 15 parts; citric acid, 8 parts. The product corresponds to 20 parts of true quinine citrate.

Quinine Hydrobromate. Quinine sulphate, 100 parts; potassium bromide, 28 parts. The product corresponds to 100 parts of quinine hydrobromate. Quinine hydrobromate contains almost as much quinine as the bisulphate, and is soluble in 54 parts of water. It has been extensively used hypodermically in the form of a ten-per-cent. solution in a mixture of 25 parts of alcohol and 75 parts of water. Its simple aqueous solution seems to be preferable.

Quinine Hydriodate. Quinine sulphate, 95 parts; potassium iodide, 40 parts. The product corresponds to 100 parts of quinine hydriodate.

Iodized Quinine Hydriodate. Quinine hydrochlorate, 70 parts; potassium iodide, 50 parts; iodine, 20 parts. To be triturated together with a little alcohol. Corresponds to 100 parts of the above quinine salt.

Quinine Hypophosphite. Quinine hydrochlorate, 100 parts; calcium hypophosphite, 24 parts. Corresponds to 100 parts of the above quinine salt.

Quinine Lactate. Quinine, pure, 70 parts; lactic acid, 35 parts. To be triturated together, if necessary, with a few drops of alcohol. Corresponds to 100 parts of the above quinine salt.

Quinine Phosphate. Quinine sulphate, 94 parts; sodium phosphate, 80 parts. Corresponds to 100 parts of the above quinine salt. (*Journ. de Pharm. et de Chim.*, May, 1879; *N. R.*, Nov. 1879.

Quinine sulphovinate, according to Carles, is prepared by dissolving 16·9 parts of sodium sulphovinate in 200 parts of hot alcohol, and 42·8 parts of quinine sulphate in 600 parts of hot alcohol. The hot solutions are mixed, cooled, and the precipitated sodium sulphate filtered out. The filtrate is distilled, and the residue evaporated and dried at a low temperature. It is soluble in 3 parts of water. Dr. Jaillarl has extensively employed hypodermic injections of one part of quinine sulphovinate in nine parts of distilled water, with great satisfaction, in the severe *malarial fevers of Algiers*.

Quinine salicylate may be prepared by Jobst's process, by double decomposition between solutions of quinine hydrochlorate and ammonium salicylate, or by saturating an alcoholic solution of quinine with an alcoholic solution of salicylic acid. The crystals are soluble in 225 parts of water and in 20 parts of alcohol.

Quinine phenate, or *carbolate*, is obtained by Jobst, having the composition $C_{20}H_{24}N_2O_2,C_6H_6O$. It is soluble in

QUININÆ BISULPHAS. U. S. Quinine Bisulphate.

(QUĪ-NĪ'NÆ BĪ-SŬL'PHĂS.)

$C_{20}H_{24}N_2O_2H_2SO_4.7H_2O$; 546·88. $C_{20}H_{24}N_2O_2H_2SO_4.7H_2O$; 548.

"Quinine Bisulphate should be kept in well-stoppered bottles, in a dark place." *U. S.*

This is a new official salt. It is made by suspending quinine sulphate in water, and adding a molecule of sulphuric acid, filtering and crystallizing. It has been introduced because of the great advantages in solubility that it possesses over the ordinary sulphate. It requires but 10 parts of water to dissolve it, whilst the sulphate requires 740. For use in the form of pills it is greatly superior on this account, whilst it may be administered in solution without the excess of acid which must be used when the ordinary sulphate is prescribed in order to dissolve it. Its use is rapidly extending, and when these very important practical points of superiority are fully appreciated by the profession it will be used almost exclusively. It is officially described as in "colorless, transparent or whitish, orthorhombic crystals or small needles, odorless, and having a very bitter taste. Effloresing on exposure to the air. Soluble, at 15° C. (59° F.), in 10 parts of water, and in 32 parts of alcohol; very soluble in boiling water and in boiling alcohol. When heated at 100° C. (212° F.), the salt loses all its water of crystallization (nearly 23 per cent.); at 135° C. (275° F.), it is converted into quinicine sulphate, which dissolves in diluted sulphuric acid with a yellow color without any blue fluorescence. On ignition, the salt is slowly consumed, leaving no residue. The aqueous solution of the salt has a strongly acid reaction, and a blue fluorescence. On treating 10 C.c. of an aqueous solution (about 1 in 1000) of the salt with 2 drops of bromine test-solution, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution of the salt throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid. Quinine Bisulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*). If 1 Gm. of the salt be dried at a temperature of 100° C. (212° F.), until it ceases to lose weight, the remainder, cooled in a desiccator, should weigh not less than 0·77 Gm. (corresponding to 7 molecules, or 23 (22·98) per cent. of water of crystallization). If 2 Gm. of the salt, dried at 100° C. (212° F.), be agitated with 16 C.c. of water, the mixture made exactly neutral with ammonia water, then brought to the volume of 20 C.c. by the addition of water, and macerated for half an hour at 15° C. (59° F.), upon proceeding further as directed for the corresponding test under Quinine (see *Quinina*) the results there given should be obtained." *U. S.*

On account of its great solubility this salt is to be preferred to the neutral salts whenever rapid absorption is desired, and especially for hypodermic medication. Its dose is about 15 per cent. greater than that of the sulphate, on account of its greater proportion of acid.

QUININÆ HYDROBROMAS. U. S. Quinine Hydrobromate.

(QUĪ-NĪ'NÆ HĪ-DRŌ-BRŌ'MĂS.)

$C_{20}H_{24}N_2O_2HBr.H_2O$; 422·06.

"Quinine Hydrobromate should be kept in well-stoppered bottles, in a dark place." *U. S.*

This official salt may be made by suspending 10 parts of quinine sulphate in 80 parts of water, boiling, and adding 3·4 parts of barium bromide dissolved in 20 parts of water, fil-

400 parts of water, and in 80 parts of alcohol. (*P. J. Tr.*, June 12, 1875.) *Quinine sulphosalicylate*, on account of its slow solubility in water, will probably not be very useful medically. (See *N. R.*, 1878, p. 103.) *Quinine meconate* is prepared by mixing alcoholic solution of meconic acid and quinine.

Quinine chlorate is best prepared, according to Mr. C. R. C. Tichborne, from barium chlorate. He mixes in a porcelain dish 310 grains of barium chlorate dissolved in a little boiling water with 2 ounces avoirdupois of quinine sulphate, and 12 ounces of hot water, at 90° C. (194° F.), a slight excess of the sulphate being used to insure the precipitation of all the barium. Owing to this excess, a slight pellicle of quinine sulphate floats on the surface. Apply heat, and gradually add a very little precipitated barium carbonate till the coating of sulphate is replaced by a slightly oily pellicle of alkaloid. The quinine chlorate is now obtained by evaporation and crystallization. For a mode of preparing the barium chlorate, see *A. J. P.*, 1868, p. 101.

The chlorate crystallizes from its solution in fungoid tufts, consisting of filiform, snow-white crystals, radiating from a centre. It melts with heat, and in the air at length takes fire, burning vividly, and if dry sometimes with explosion, leaving a carbonaceous residue. It is very soluble in boiling water, but sparingly in cold, and is deposited from its hot solution on cooling. Gently warmed with hydrochloric acid, it emits chlorine copiously; and ammonia now added in excess occasions an emerald-green color,—thus showing that it is a compound of chloric acid and quinine. (*P. J. Tr.*, 2d ser., viii. 135.)

tering, evaporating, and crystallizing. It may also be made by Leger's process, as follows. Quinine sulphate, commercial, crystallized, 40 parts; potassium bromide, dried and powdered, 11 parts; alcohol (80 per cent.), 400 parts; distilled water, 400 parts. Dissolve the sulphate in two hundred parts of alcohol by the aid of heat, add the potassium bromide, dissolved in thirty parts of distilled water, and continue the heat five or six minutes, in order to allow the potassium sulphate, which is formed, to acquire greater compactness, so that it will more readily settle. Filter off from the precipitate, and wash four times with fifty parts of boiling alcohol. Let the alcoholic solution cool, when a further small quantity of potassium sulphate will be deposited. The solution is then again filtered through white filtering paper, and evaporated on a water-bath to one hundred parts. Next, four hundred parts of distilled water are poured on, and heat is applied until the hydrobromate is completely dissolved. After allowing the solution to stand in the cold for about twenty-four hours, the capsule will be found filled with a compact crystalline mass. The crystals are transferred to a filter, allowed to drain, and dried by exposure to air. Heating would cause them to fuse. The product thus obtained amounts to about thirty parts of perfectly white quinine hydrobromate. By evaporating the mother-water to one-third of its volume, about six parts more may be obtained. It is absolutely necessary, as has been already pointed out by Boille, to redissolve the hydrobromate in water as above stated, if the salt is to be obtained in white and bulky crystals. The above quantity of four hundred parts should not be diminished, for, if this were done, the salt (which fuses at 90° F.) would separate at first in the form of an oily liquid, and afterwards would form a crystalline crust. (*Répert. de Pharm.*, 1880, p. 390; *N. R.*, Jan. 1881.)

Properties. It is in "white, light, silky needles, odorless, and having a very bitter taste. The salt is liable to lose water on exposure to warm or dry air. Soluble, at 15° C. (59° F.), in 54 parts of water,* and in 0·6 part of alcohol; very soluble in boiling water and in boiling alcohol; also soluble in 6 parts of ether, and in 12 parts of chloroform. When heated at 100° C. (212° F.), the salt loses its water of crystallization (4·25 per cent.). At 152° C. (305·6° F.), it begins to fuse, and becomes a syrupy liquid at 200° C. (392° F.). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution, when acidulated with sulphuric acid, has a vivid, blue fluorescence. On treating 10 C.c. of an aqueous solution (about 1 in 1300) with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. On precipitating a saturated aqueous solution of the salt with sodium hydrate test-solution, filtering, supersaturating the filtrate with acetic acid, adding chloroform and a little chlorine water, and shaking, the chloroform will separate with a yellow color. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should not weigh less than 0·957 Gm. (corresponding to 1 molecule, or 4·24 per cent., of water of crystallization). Quinine Hydrobromate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If 3 Gm. of the salt (which must have been previously ascertained to be strictly neutral, or have been rendered so) be mixed, in a small capsule, with 1·2 Gm. of crystallized sodium sulphate and 30 C.c. of water, the mixture thoroughly dried on a water-bath, the residue agitated with 30 C.c. of water, and allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*) the results there given should be obtained." *U. S.*

Medical Properties. This salt is well fitted for hypodermic injection, on account of its ready solubility, but is not superior, if equal, to the bisulphate. The plan which has been advocated of injecting a hot saturated solution is to be deprecated, as tending to cause precipitation in the cellular tissue. It is very capable of causing cinchonism, but the amount of hydrobromic acid is too small to sensibly affect the system. Dose, that of quinine sulphate.

* Dr. E. R. Squibb found that official quinine hydrobromate required 53 parts of water to dissolve it, and that the *quinine acid-hydrobromate* or *dihydrobromate* corresponded more nearly with the official description of the hydrobromate. (*Ephemeris*, 1888, 1103.)

QUININÆ HYDROCHLORAS. U. S. (Br.) Quine Hydrochlorate.

(QUĮ-NĪ'NÆ HŸ-DRO-ȼHLŌ'RĂS.)

$C_{20}H_{24}N_2O_2HCl.2H_2O$; 395·63.

"Quinine Hydrochlorate should be kept in well stoppered bottles, in a dark place." *U. S.*

"The hydrochloride, $C_{20}H_{24}N_2O_2,HCl,2H_2O$, of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.*

Quininæ Hydrochloridum, *Br.*, Quinine Hydrochloride.

This quinine salt was recommended for admission to the Br. Ph. 1885 by W. Martindale on account of its being more soluble in water and richer in quinine than is the sulphate. It may be readily prepared by treating the alkaloid with diluted hydrochloric acid, or by double decomposition between barium chloride and quinine sulphate. Quinine hydrochlorate is in "white, silky, light and fine, needle-shaped crystals, odorless, and having a very bitter taste. The salt is liable to lose water when exposed to warm air. Soluble, at 15° C. (59° F.), in 34 parts of water, and in 3 parts of alcohol; in 1 part of boiling water, and very soluble in boiling alcohol; also soluble in 9 parts of chloroform. When heated to 120° C. (248° F.), the salt loses its water of crystallization. At about 156° C. (312·8° F.), it begins to melt, but it is not fully melted until the temperature reaches 190° C. (374° F.). On ignition, it is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral or faintly alkaline to litmus paper. The saturated aqueous solution of the salt does not give any blue fluorescence, which, however, appears to some extent upon diluting the solution with water, and markedly so upon addition of dilute sulphuric acid.* On treating 10 C.c. of an aqueous solution (about 1 in 1400) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with silver nitrate test-solution, a white precipitate insoluble in nitric acid. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should not weigh less than 0·91 Gm. (corresponding to 2 molecules, or 9 per cent., of water of crystallization). Quinine Hydrochlorate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). The aqueous solution of the salt should not be rendered turbid by diluted sulphuric acid (absence of *barium*), and should not be rendered more than slightly turbid by barium chloride test-solution (limit of *sulphate*). If 3 Gm. of the salt (which must have been previously ascertained to be strictly neutral, or have been rendered so) be mixed, in a small capsule, with 1·5 Gm. of crystallized sodium sulphate and 30 C.c. of water, the mixture thoroughly dried on a water-bath, the residue agitated with 30 C.c. of water, and allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*) the results there given should be obtained." *U. S.* "It is soluble in about 35 parts of cold *water*, in 3 parts of cold *alcohol* (90 per cent.), and very soluble in boiling *water* and *alcohol* (90 per cent.). It affords the reactions characteristic of hydrochlorides. It should yield only the slightest characteristic reactions with the tests for sulphates. When converted into quinine sulphate, by dissolving it together with an equal weight of *sodium sulphate* in ten times its weight of hot *water*, and setting the mixture aside at 60° F. (15·5° C.), it should respond to the characters and tests that are mentioned under 'Quininæ Sulphas.' Dried at a temperature of 212° F. (100° C.), it loses 9 per cent. of water." *Br.*

Quinine hydrochlorate has a decided advantage over the sulphate in its greater solubility in water. It is, however, less soluble than the acid quinine hydrochloride (see below). The dose is the same as that of the sulphate.

QUININÆ HYDROCHLORIDUM ACIDUM. Br. Acid Quinine Hydrochloride.

(QUĮ-NĪ'NÆ HŸ-DRO-ȼHLŌ'RĮ-DŬM ĂȻ'Į-DŬM.)

$C_{20}H_{24}N_2O_2.2HCl.3H_2O$; 449·96.

"The acid hydrochloride, $C_{20}H_{24}N_2O_2,2HCl,3H_2O$, of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.*

* In explanation of this it may be stated that it is only the compounds of quinine with the oxygen acids that show the fluorescence in acid solution, none of the compounds of the haloid acids showing this reaction.

This is a new official quinine salt of the Br. Ph. 1898. It has been introduced on account of its remarkable solubility in water,—*i.e.*, less than its own weight. It may be made by passing hydrochloric acid gas over dry quinine, but more conveniently by decomposing quinine sulphate with barium chloride or by mixing a solution of neutral quinine hydrochloride with one molecular proportion of hydrochloric acid and evaporating the solution at a gentle heat. It is officially described as "A white crystalline powder soluble in less than its own weight of *water*, yielding a somewhat acid liquid. It affords the reactions characteristic of hydrochlorides. It should yield only the slightest characteristic reactions with the tests for sulphates. Each gramme, when dissolved in 20 cubic centimetres of *water*, should require for its complete neutralization not more than 2·5 cubic centimetres of *volumetric solution of soda*. When converted into quinine sulphate, by dissolving it together with an equal weight of *sodium sulphate* in ten times its weight of hot *water*, exactly neutralizing this liquid with *solution of ammonia*, and setting it aside at 60° F. (15·5° C.) to cool, it should respond to the characters and tests which are mentioned under 'Quininæ Sulphas.' Dried at a temperature of 212° F. (100° C.), it loses not more than 12 per cent. of water." *Br.*

The solubility of this salt fits it for use in hypodermic and rectal injections. Its physiological and therapeutic action and its dose are those of quinine sulphate.

QUININÆ SULPHAS. U. S., Br. Quinine Sulphate.

(QUĮ-NĪ'NÆ SŬL'PHĂS.)

$(C_{20}H_{24}N_2O_2)_2H_2SO_4.7H_2O$; 870·22.

"Quinine sulphate should be kept in well-stoppered bottles, in a dark place." *U. S.* "The sulphate, $\{(C_{20}H_{24}N_2O_2)_2,H_2SO_4\}_2,15H_2O$, of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.*

Chininum Sulfuricum, *P. G.;* Sulfas Quinicus; Disulphate or Basic Sulphate of Quinia; Sulfate de Quinine, *Fr.;* Schwefelsaures Chinin, *G.*

No process is given in the U. S. Pharm. 1890 for preparing quinine sulphate; that of the U. S. P. 1870 will be found in detail in the U. S. D., 17th ed., p. 1141. The process, briefly stated, is to exhaust cinchona bark by boiling with water acidulated with hydrochloric acid and add milk of lime in excess. The quinine is precipitated with the lime, and the dried precipitate digested with boiling alcohol; the alcoholic solution of quinine is evaporated, and the mass dissolved in water acidulated with sulphuric acid. The hot solution is treated with animal charcoal to decolorize it, and then set aside to crystallize.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process for procuring quinine sulphate. The impure quinine, precipitated by lime from the acidulous decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinine. The solution thus obtained is agitated with water acidulated with sulphuric acid, by which quinine sulphate is formed. The oil, separating, rises to the top, and is removed for future use; and the watery solution of the salt is evaporated, and treated as in the original process. A disadvantage of this method is said to be that the oil does not completely exhaust the precipitate. A similar process has been employed here and in England, either *fusel oil* or *benzene* being substituted for oil of turpentine. In this instance, however, the solvent is added to the impure quinine, without separation from the acidulated decoction from which it was precipitated by lime. The mixture being well agitated, the fusel oil or benzene dissolves the alkaloids, and, rising to the surface of the liquid, is drawn off by a siphon. The solution thus drawn off is treated as above with water acidulated with sulphuric acid, and the process is completed in the same manner. (See *P. J. Tr.*, xiv. 29, 92, and 139.)

The importation of quinine sulphate and salts of quinine amounted in 1895 to 1,420,649 ounces, valued at $342,348; in 1896 to 3,359,818 ounces, valued at $786,887; in 1897 to 3,517,844 ounces, valued at $582,945. For a "commercial history of quinine," with statistics, see *Drug. Circ.*, 1896, 32. Quinine sulphate made in Java is beginning to enter commerce. (*A. J. P.*, 1898, 345.)

When barks containing the alkaloids *cinchonidine* and *quinidine* are used, as their sulphates are much more soluble than that of quinine, it follows that in the mother-waters left after the crystallization of quinine sulphate there will be found a portion of cinchonidine or quinidine sulphate, or of both. In fact, there is generally, under these circumstances, more or less of the sulphates of the four alkaloids, quinine, cinchonine, quinidine, and cinchonidine, all of which are contained in many barks, and, besides these, a portion of amorphous alkaloid, incapable of crystallization, probably resulting, in part at least, from the heat employed in the

process. These may in a great degree be separated through their different solubilities in water. Quinine sulphate, being least soluble, will first crystallize, afterwards the cinchonidine or quinidine salt, and finally that of cinchonine, which is the most soluble of the four; while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties. "White, silky, light and fine, needle-shaped crystals, fragile and somewhat flexible, making a very light and easily compressible mass, lustreless from superficial efflorescence after being for some time exposed to the air, odorless, and having a persistent, very bitter taste. The salt is liable to lose water on exposure to warm air, to absorb moisture in damp air, and to become colored by exposure to light. Soluble, at 15° C. (59° F.), in 740 parts of water, and in 65 parts of alcohol; in 30 parts of boiling water, and in 3 parts of boiling alcohol; also in 40 parts of glycerin, in about 680 parts of chloroform, and freely in dilute acids. When long exposed to the air, or when kept at 50° to 60° C. (122° to 140° F.) for some hours, it loses most of its water of crystallization (all except 2 to 3 molecules, or about 4·1 to 6·2 per cent.), the last portion being slowly expelled at 100° C. (212° F.), more rapidly at 115° C. (239° F.). Upon ignition, the salt is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and has, especially when acidulated with sulphuric acid, a vivid, blue fluorescence. On treating 10 C.c. of an aqueous solution (about 1 in 1300) of the salt with 2 drops of bromine water, then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate." *U. S.* "Filiform silky white crystals, of an intensely bitter taste. Soluble in about 800 parts of *water*, giving a solution which has a bluish fluorescence. Entirely soluble in *water* acidulated with a mineral acid. Aqueous solutions of quinine salts yield with *solution of ammonia* white precipitates, soluble in *ether* and in excess of the *solution of ammonia*. When such aqueous solutions are treated first with *solution of bromine* or *of chlorine* and afterwards with *solution of ammonia*, they become of an emerald-green color, changing to red when mineral acids are added. Exposed to dry air, Quinine Sulphate effloresces until the 15 molecules of water have been reduced to 4. It affords the reactions characteristic of sulphates." *Br.* Its cold solution is opalescent. The acid quinine salts possess fluorescent properties with the exception of those of the haloid acids. It has also been discovered that the presence of phenacetin conceals the fluorescence of sulphuric acid solutions of quinine. The diluted acids, and tartaric and oxalic acids in excess, dissolve the sulphate easily. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the official salt, and crystallizes from its solution with much greater difficulty. This is now considered by many as strictly neutral, and therefore entitled to the name of quinine sulphate; while the official salt contains two equivalents of base to one of acid, and is therefore a *quinine subsulphate* or *disulphate*. The latter name was adopted by the London College, and has been much used by chemical writers. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of quinine sulphate, originally given to the official salt, under the impression that it was neutral, was retained; and it has been assumed in the new British Pharmacopœia. Hence has arisen a confusion of nomenclature, which must be embarrassing to the student. The following statement may serve to clear up this confusion. There are at least three quinine sulphates that have been obtained, of which two are now official. The first of these, $(C_{20}H_{24}N_2O_2)_2H_2SO_4 + 7H_2O$, is a "*diquinic sulphate*," but is the official salt known as quinine sulphate, or *Quininæ Sulphas, U. S.*; the second, formed by dissolving this first in dilute sulphuric acid, has the formula $C_{20}H_{24}N_2O_2.H_2SO_4 + 7H_2O$, and is the official quinine bisulphate, or *Quininæ Bisulphas, U. S.*; while the third, a still more acid sulphate, $C_{20}H_{24}N_2O_2,2H_2SO_4 + 7H_2O$, may be obtained from a solution of quinine in excess of diluted sulphuric acid. This last salt is not official. Quinine sulphate, owing to the ease with which it parts with its water of crystallization, is apt to mislead those who seek to determine its quality. Forty samples examined by A. J. Cownley showed results varying from 8·1 to 15·95 per cent. of water of crystallization. He recommends for adoption in the Pharmacopœia the air-dried salt, which contains two molecules of water (4·6 per cent.), as being constant in composition. Farr and Wright confirm Cownley's views, and object to "anhydrous" quinine sulphate, which has been proposed by some chemists as the standard, because it has the opposite fault of absorbing moisture. (*P. J. Tr.*, 1896, 525; also *P. J. Tr.*, 1897, 203.)

Incompatibles and Tests. "A cold, saturated aqueous solution of the salt remains unaffected by potassium iodide test-solution (difference from *quinidine sulphate*). Ammonia

water added to the aqueous solution of the salt throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid. Quinine Sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If 1 Gm. of the salt be dried at a temperature of 115° C. (239° F.), until it ceases to lose weight, the residue should not weigh less than 0·838 Gm. (absence of *more than eight* (8) *molecules*, or 16·18 per cent. of *water*). If 2 Gm. of the salt (which must have been previously ascertained to be strictly neutral to litmus paper, or have been rendered so) be dried, as far as possible, at 100° C. (212° F.), the residue then agitated with 20 C.c. of water, and the mixture macerated for half an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*) the results there given should be obtained." *U. S.* "2·5 grammes of the freshly prepared salt should lose 0·38 gramme of water by drying at 212° F. (100° C.). Heated to redness with free access of air, it burns without leaving any residue (absence of mineral impurity)." *Br.* The official test (see below) is probably the most reliable of all to prove the presence of small quantities of other cinchona alkaloids. It is a modification of Kerner's,* and admits the presence of a trace of the other alkaloids. This certainly is as pure as the quinine sulphate need be. To separate the remaining trace of alkaloids entirely would more than double the cost of the salt. For Herapath's test (*quinine iodo-sulphate*), see U. S. D., 17th ed., p. 1144. The British Pharmacopœia gives the following tests for the presence of other cinchona alkaloids:

"Quinine Sulphate when tested by the following methods should not afford any appreciable reaction characteristic of cinchonine, quinidine, cupreine, or amorphous alkaloid, and should not yield more than a total of 3 per cent. of crystals of impure cinchonidine by the following test.

"*Test for Cinchonidine and Cinchonine.*—Dissolve 4 grammes of the Quinine Sulphate in 120 cubic centimetres of boiling *water*. Cool the solution slowly to 122° F. (50° C.), with frequent stirring. Separate, by filtration, the purified quinine sulphate which has crystallized out. Concentrate the filtrate by evaporation until it is reduced to 10 cubic centimetres or less; transfer to a small stoppered flask, and, when cold, shake with 10 cubic centimetres of *ether* and half that amount of *solution of ammonia*. Set aside in a cool place for not less than 24 hours. Collect the crystals, which consist of cinchonidine and cinchonine combined with quinine, on a tared filter, wash with a little *ether*, dry at 212° F. (100° C.), and weigh. These should not amount to more than 0·12 gramme.

"*Test for Quinidine.*—Dissolve 1 gramme of the Quinine Sulphate in 30 cubic centimetres of boiling *water;* cool, and filter. To the solution add *solution of potassium iodide* and a little *alcohol* (90 per cent.) to prevent the precipitation of amorphous hydriodides. Collect any separated quinidine hydriodide, wash with a little *water*, dry and weigh. The weight represents about an equal weight of crystallized quinidine sulphate. None or only the slightest traces should be obtained.

* *Kerner's test* (Dr. G. Kerner, *Zeitschrift für Analytische Chemie*, 1862) distinguishes the alkaloids by their solubilities in ammonia water of given strength, which, according to Dr. Kerner, are more fixed and reliable than their solubilities in water or other ordinary solvent. The mode of application is by taking a certain quantity of the sulphate of the alkaloid dissolved in a certain quantity of water, and then adding the ammonia water gradually until the precipitated alkaloid is redissolved: the quantity of the ammoniacal liquid necessary to produce this effect indicates inversely the solubility of the alkaloid. Quinidine requires from 10 to 11 times more of the ammoniacal liquid than quinine, cinchonidine from 12 to 13 times more; while cinchonine is not dissolved by a much larger proportion than is required by either of the others, and though when mixed in very small proportion with quinine it is dissolved at first, yet it afterwards separates on standing. This test is now official, and as modified is regarded as the best test for quinine sulphate. Kerner's test has been elaborately criticised and discussed; it appears that in order to get results which are at all trustworthy it is necessary to be exceedingly careful to observe the specific gravities and temperatures ordered by the test. (See Prof. Parson's paper, *Proc. A. P. A.*, 1884; *Amer. Drug.*, 1885, also 1888; *Drug. Circ.*, 1885; *P. J. Tr.*, 1887; *Pharm. Era*, 1887, also 1888.) In *De Vrij's Chromate Test for Quinine* 5 Gm. of quinine sulphate are dissolved in 500 Gm. of water at the boiling temperature, and 1·20 Gm. of potassium chromate dissolved in a little hot water are added. The precipitate at first produced is rapidly redissolved, and in from 5 to 10 seconds crystallization begins, star-shaped groups of sulphur-yellow needles of anhydrous quinine chromate—$2(C_{20}H_{24}N_2O_2)H_2CrO_4$—being formed. The separation of these crystals is practically complete when the liquid has cooled, but it is advisable not to collect the crystals before the day following their formation. They are washed with a small quantity of water, dried, and weighed; 766·5 parts of quinine chromate are equal to 648 parts of quinine or to 890 parts of quinine sulphate. The mother-liquors contain the cinchonidine, together with a small quantity of quinine chromate amounting to 0·05 Gm. in 100 Gm., and to this extent the yield of quinine chromate, by weighing, must be corrected. To ascertain the amount of cinchonidine present the total filtrate and washings are rendered alkaline by soda solution and evaporated to 300 Gm. The cinchonidine separates during the heating, and, after cooling, is collected on a filter, dried at 100° C., and weighed. (*Arch. de Pharm.*, 1886, p. 1022.)

"*Test for Cupreine.*—Shake the recrystallized quinine sulphate, obtained in testing the original Quinine Sulphate for cinchonidine and cinchonine, with 25 cubic centimetres of *ether* and 6 cubic centimetres of *solution of ammonia*, and to this ethereal solution, separated, add the ethereal liquid and washings also obtained in testing the original sulphate for the two alkaloids just mentioned. Shake this ethereal liquid with 6 cubic centimetres of a 10 per cent. solution of *sodium hydroxide*, adding *water* if any solid matter should separate. Remove the ethereal solution. Wash the aqueous solution with more *ether*, and remove the ethereal washings. Add *diluted sulphuric acid* to the aqueous liquid heated to boiling, until exactly neutral. When cold, collect any crystallized sulphate of cupreine on a tared filter; dry, and weigh. None or only the slightest traces should be obtained.

"*Test for Cinchonine and Amorphous Alkaloids.*—Dissolve 1 gramme of the Quinine Sulphate in 30 cubic centimetres of boiling *water*, add 1 gramme of *sodium potassium tartrate*. Allow to cool, with frequent stirring; filter. The solution when evaporated to small bulk should give little or no precipitate with *solution of ammonia*."

Quinine sulphate is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution it affords white precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinine. The soluble salts of lead and of baryta occasion precipitates; and that produced by the salts of baryta is insoluble in the acids. The soluble salts of acetic, oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of quinine sulphate without excess of acid. A solution of chlorine added to a solution of quinine sulphate and followed by the addition of ammonia water occasions an emerald-green color, and, in certain proportions, the deposition of a green precipitate. The green compound has received the name of *thalleioquin*. The drop of ammonia should be put in without agitation. According to Flückiger, $\frac{1}{5000}$ part of quinine can thus be found. With bromine instead of chlorine the test is more delicate. Flückiger states that $\frac{1}{20000}$ part of the alkaloid can be detected. (See a paper by C. F. Zeller, *A. J. P.*, 1880, p. 385; *P. J. Tr.*, 1872, p. 901.) F. S. Hyde (*Proc. A. P. A.*, 1897, 704) states that a solution of calcium hypochlorite gives more satisfactory results in the thalleioquin test than either chlorine or bromine water, the results being more certain and brilliant. If, previously to the use of ammonia in the chlorine test, a concentrated solution of potassium ferrocyanide be added, a dark red color is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonine; and, though quinidine sulphate gives the same red color, this does not disappear as with the quinine salt, but is persistent. (Schwartzer, *Journ. de Pharm.*, 4e sér., iii. 475.) Quinine sulphate gives a reddish-brown precipitate with iodine dissolved in a solution of potassium iodide. It is possible that under some circumstances the galvanic current may be of service in detecting the alkaloid; a paper on the electrolysis of the salt will be found in the *Journ. de Pharm.*, 4e sér., xi. 16.* For valuable comments on quinine sulphate tests, see *Proc. A. P. A.*, 1897, 705.

Adulterations. Quinine sulphate has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which quinine sulphate may contain, without any observable alteration in its sensible properties. MM. Millon and Commaille, having exposed quinine sulphate to a very moist atmosphere at the temperature of about 16·6° C. (62° F.), found it always to increase in weight, so that a specimen of the salt, previously deprived of all its water capable of being separated by heat, had in five days absorbed 28·77 per cent. of water, and another specimen dried after its precipitation simply by draining, and supposed to contain 18 per cent. of water, had in ten days absorbed 14 per cent. more, making its whole percentage of water 32, or about one-third of its weight. (*Journ. de Pharm.*, Nov. 1862, p. 379.) This is an important fact, and will explain to some extent the frequent variable effects from apparently the same quantity of the salt. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 100° C. (212° F.) The loss of weight will indicate the quantity of water not essential to the salt. Calcium sulphate,† and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin, caffeine, salicin, phlorizin,

* Morphine has been mixed with quinine with fatal results. If there be more morphine than will form $\frac{1}{10000}$ part of the solution, the thalleioquin test will fail to develop the green color. The morphine in these cases is to be recognized by adding nitric acid or ferric chloride to the suspected powder, or, better still, iodic acid, which is decomposed by the alkaloid and forms a beautiful violet solution with chloroform. This test is said to succeed with solutions containing less than $\frac{1}{100000}$ part of morphine. (*P. J. Tr.*, May, 1872, 901.)

† *Flora China.* According to W. A. Puckner (*West. Drug.*, 1896, 393), nearly pure crystallized calcium sulphate in fine needle-shaped crystals has been exploited as quinine sulphate under the name of flora china.

and the cinchonine sulphates, and sulphates of other cinchona alkaloids, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance not readily volatilizable may be at once ascertained by exposing the salt to a red heat, which will completely dissipate the quinine sulphate, leaving the mineral behind. A volatile ammonium salt may be detected by the smell of ammonia emitted upon the addition of potassa. The absence of organic substances may be inferred if pure cold concentrated sulphuric acid forms a colorless solution. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste after the precipitation of the quinine by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid; but, according to Pelletier, this change of color does not take place unless the proportion of salicin exceeds one-tenth. If only in this proportion, the salicin must be isolated. To 1 part of the suspected salt, 6 parts of concentrated sulphuric acid may be added, and to the brown liquid which results, 125 parts of water. The salicin is thus separated, and may be obtained by filtration, in the form of a bitter, white powder, becoming bright red with sulphuric acid. (See *A. J. P.*, xvii. 156.) Caffeine alters the solubility of the medicine in different menstrua. According to M. Calvert, a saturated solution of quinine sulphate in cold water gives with a solution of chlorinated lime a precipitate soluble in an excess of the latter; while a solution of cinchonine sulphate of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime water, and with solution of ammonia; and solution of calcium chloride, while it furnishes a precipitate with a solution of cinchonine sulphate, yields none with a solution of quinine sulphate. (*Journ. de Pharm.*, 3e sér., ii. 394.) Though commercial quinine sulphate frequently contains a portion of one or more of the cinchona alkaloids, the salt is slightly less efficacious on that account, as these alkaloids have been shown to possess identical therapeutic properties with those of quinine, and to be little inferior in strength to them.

Medical Properties and Uses. The first symptoms of cinchonism, as produced by small therapeutic doses of quinine (ten grains) in man, are usually ringing in the ears, slight fulness in the head, and perhaps some deafness. With the use of larger doses these symptoms are intensified; the deafness is very marked, disturbed vision may exist, and the flushed face, with the sense of distention in the head, may point towards a cerebral congestion, which is in some cases relieved by spontaneous epistaxis. In decided cinchonism, giddiness and staggering in walking are very common. After toxic doses, severe headache, delirium, stupor, complete deafness and blindness, dilated pupils, embarrassment of respiration, great weakness, convulsions, paralysis, and finally collapse, may result, either comatose or delirious. The deafness produced by large doses of quinine usually passes off rapidly: very rarely is there a permanent impairment of hearing. Amaurosis, with a peculiar ischæmia of the retinal vessels, has in a small number of cases been produced by very large therapeutic doses of the alkaloid. Besides its effects on the brain, quinine sulphate sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general, these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer, and permanent deafness has resulted. It is capable of taking life, although enormous amounts of it are requisite for this. Several cases of recovery are recorded after the taking of an ounce by the stomach. Probably only a portion of the drug was absorbed. Five ounces taken in ten days have caused death.

Although it is not possible at present to establish the connection between the known physiological action of quinine and its clinical use, yet it seems proper to speak here briefly of our knowledge of its influence upon the healthy organism, referring the reader for details to H. C. Wood's Treatise on Therapeutics. The action of the drug upon the cerebrum is somewhat uncertain. It is probable that moderate doses stimulate the brain to some extent, especially the basal ganglia connected with the special senses, and it is very certain that toxic doses overwhelm and paralyze the gray matter of the brain. Upon the spinal cord of man therapeutic doses produce no marked effect. Two facts, first pointed out by Dr. T. A. Chaperon (*Pflüger's Archiv*, 1869, p. 295), have been so abundantly substantiated that we must accept them as established. They are—quinine in *small* doses causes in the frog a lessening of the reflex

activity, which is removed by section of the medulla; quinine in *large* doses produces a permanent palsy of reflex activity. The first of these actions is considered to show that the alkaloid stimulates Setschenow's centre in the base of the brain, the second is probably due to a paralysis of the spinal cord. It has been proved by Prof. Binz and subsequent observers that when the alkaloid is added to blood outside of the body in a proportion of not less than one part to four thousand it immediately checks, and finally arrests, the amœboid movements of the white blood-corpuscles. How far this occurs when the medicine has been taken into the living organism has not been exactly determined, but we certainly are not able to appreciate any such effect in health or disease by therapeutic doses. The ozonizing power of the red corpuscles in drawn blood is lowered by the addition of quinine. Ordinary therapeutic doses exert, however, no perceptible influence. How far the marked antipyretic influence exerted by large doses of quinine is dependent upon its action upon the blood is at present purely a matter of conjecture. In 1765, Dr. Pringle called attention to the power of cinchona bark over putrefaction, and it has recently been experimentally proved by Binz, Hallier, Pavesi, and others, that one part of the alkaloid in three hundred parts of milk, albuminous solutions, meat, honey, syrup, etc., will keep in check for a long time putrefaction and other fermentations. Prof. Binz has shown that this is due to a poisonous influence upon the low forms of life which accompany or produce these changes. Introduced into the jugular vein or coronary artery, or in any way brought in direct contact with the heart, it lessens the force and frequency of the pulsations, and finally produces diastolic arrest. In man, very large doses of quinine (thirty to sixty grains) lower the force and frequency of the pulse; a pulse-rate of forty has been noted, and in reported cases of quinine-poisoning the pulse has been imperceptible at the wrist. Under the latter circumstances the pulse-rate may be increased, but the cardiac force is reduced to a minimum. The evidence is conclusive that both in man and in the lower animals quinine in sufficient amount is a powerful depressant to the heart-muscle or ganglia. An enormous amount has been written during the last ten years concerning the action of quinine upon the uterus. The result of it all seems to indicate very positively that the alkaloid has no power to originate uterine contractions in the pregnant female, but that when once parturition has commenced the flagging pains are greatly stimulated and increased by a dose of ten grains of the drug. When abortion is threatened through malarial influence, no hesitation need be felt in using the drug to avert the impending catastrophe. Any salt of quinine which escapes absorption in the stomach must be precipitated by the alkaline juices of the bowels, and be absorbed very slowly or not at all. What seems *a priori* almost inevitable has been shown to be the case by the researches of Kerner, who found the alkaloid in the fæces. The importance of giving the salt in some easily soluble form, if it is intended for all of it to be absorbed, is plain. When taken into the system, it seems to find its way into all the secretions,—it having been found in the tears, sweat, milk, urine, and saliva. Some of it is eliminated unchanged, but, according to the researches of Dr. G. Kerner, a portion of it escapes in an amorphous uncrystallizable form and a second portion as a substance free from bitter taste, though crystallizable and having the fluorescence of quinine; for this substance he has proposed the name of *dihydroxyl-quinine*. Upon the elimination both of uric acid and of urea the salts of quinine appear to have a decided influence, decreasing it very noticeably.

Quinine sulphate may be given in pill or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains (0·52 Gm.) of the sulphate will dissolve in a fluidounce (30 C.c.) of water acidulated with about twelve minims (0·72 C.c.) of the diluted sulphuric acid or aromatic sulphuric acid of the Pharmacopœias. One of the best ways of exhibiting it to children is to mix the dose quickly with half a teaspoonful of aromatic elixir of liquorice (see PART II.) and administer it before it can dissolve. A few drops of laudanum may be added if nausea or disturbance of the bowels is apprehended. Mr. J. S. Blockley ascertained that glycerin will, if gently heated, dissolve eight grains of the sulphate in each fluidrachm, and may therefore be conveniently used as a vehicle. (*Lond. Chemist*, Sept. 1857.) Dr. R. H. Thomas, of Baltimore, found that one part of tannic acid will deprive five parts of quinine sulphate of bitterness, without impairing its efficacy. (*Am. Journ. of Med. Sci.*, N. S., xix. 541.) It is obvious that quinine tannate is thus formed; and as this, though insoluble in water, is readily dissolved in diluted acids, and consequently in the gastric liquor when acid, there can be no doubt that it will generally prove efficacious. It may, however, happen that the stomach may be quite free from acid, and that the operation of this salt may prove less certain than that of the sulphate; and such is asserted to

have been the case in some instances; but a little lemonade taken after the medicine would probably obviate the difficulty.

Quinine is used in practical medicine as a tonic, antiperiodic, antipyretic, and a uterine stimulant. It is certainly the most efficient remedy known in *malarial diseases*, in which it in all probability acts by poisoning the organisms first detected in the blood of persons suffering from malarial disease by Laveran, and now generally believed to be the cause of the symptoms. It should be administered in such a way that the last dose shall be ingested about two hours before the expected return of the paroxysm, and the first dose four or five hours previous to the last. When there is sufficient time, its influence is almost always very sensibly aided by the exhibition, twelve or more hours before, of a mercurial or other purge. Quinine exerts in *febrile disease* a decided antipyretic action, which is especially manifested during those stages of disease in which the natural tendency is towards a lowering of temperature. In *typhus* and *typhoid fever*, *scarlatina*, *severe erysipelas*, *rheumatic hyperexia*, etc., after the use of the cold bath, twenty grains of the alkaloid are often very efficacious in preventing a rapid return of the excessive fever.

Twelve grains of quinine sulphate are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient and the object to be accomplished. As a tonic simply, a grain (0·065 Gm.) may be given three or four times a day, or more frequently in acute cases. In *intermittents*, from twelve to twenty-four grains (0·80–1·5 Gm.) should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach or the length of the intermission. From one to four grains (0·065–0·26 Gm.) may be given at once, and some even advise the whole amount. In *malignant intermittents* and *remittents*, the quantity may be increased to thirty grains (1·95 Gm.) or even ninety (6 Gm.) between the paroxysms. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema,—from six to twelve grains (0·4–0·8 Gm.) with two fluidounces (60 C.c.) of acidulated starch water, and from twenty to forty drops (0·6–1·12 C.c.) of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, the hypodermic syringe should be resorted to. If the ordinary sulphate be used, the solution for hypodermic use should be made with tartaric acid, grain for grain, and should always be carefully filtered. The sulphovinate has been especially recommended, but is of doubtful advantage. (*P. J. Tr.*, May, 1875, p. 909.) The official hydrobromate and bisulphate have been considered the best forms for hypodermic use, but it is affirmed that *Laveran's solution* (hydrochlorate of quinine, 3, antipyrin, 2, distilled water, 6) affords a 50 per cent. solution, of which the injection is painless.* Administered hypodermically, quinine acts with great promptness; but no precaution will always prevent the production of severe local abscesses and ulcerations by the hypodermic use of quinine, and even fatal tetanus has been induced, so that the method should be employed only in emergencies.

Locally applied to the mucous membranes, quinine is stimulant or irritant, according to its concentration. In *meningitis*, *gastritis*, *enteritis*, *cystitis*, or in *inflammation of the middle ear*, its evil effects may be very pronounced. In *whooping-cough* the use of quinine by atomization has been warmly recommended. In *hay fever* a warm solution, as nearly neutral as possible, and of the strength of two grains to the fluidounce (0·13 Gm. to 30 C.c.), may be used with the Thudichum douche.

QUININÆ VALERIANAS. U. S. Quinine Valerianate.

(QUĪ-NĪ'NÆ VĄ-LĒ-RĮ-Ā'NĂS.)

$C_{20}H_{24}N_2O_2C_5H_{10}O_2.H_2O$; 443·07. $C_{20}H_{24}N_2O_2C_5H_{10}O_2.H_2O$; 444.

"Quinine Valerianate should be kept in well-stoppered bottles, in a dark place." *U. S.*

Quiniæ Valerianas, *U. S.* 1870; Chininum Valerianicum, *P. G.*; Valérianate de Quinine, *Fr.*; Baldriansaures Chinin, *G.*

No process is given for this salt; that of the U. S. P. 1870 will be found below.†

* Santesson and Sjoquist believe that a new salt is formed, to which they have given the name of *Chinopyrin*. The antimalarial powers of the solution are well attested.

† "Take of Valerianic Acid *half a troyounce*; Sulphate of Quinia *two troyounces*; Diluted Sulphuric Acid, Water of Ammonia, Water, each *a sufficient quantity*. Dissolve the Sulphate of Quinia in a pint of Water, with the aid of Diluted Sulphuric Acid; then add Water of Ammonia in slight excess, and wash the precipitated quinia with water until freed from sulphate of ammonium. Dissolve the Valerianic Acid in five pints of Water, heated to 180° F., add the quinia to the solution, and, when it is dissolved, set the whole aside for several days to crystallize. Decant the mother-water from the crystals, dry them on bibulous paper, and keep them in a well-stopped bottle. By evaporating the mother-water at a temperature not exceeding 120° F., more crystals may be obtained." *U. S.* 1870.

In the process of the U. S. P. 1870 quinine is first obtained by decomposing quinine sulphate by means of ammonia, and then combined directly with valerianic acid, to form quinine valerianate, which crystallizes from the solution when it cools, because much less soluble in cold than in hot water. By the late Dublin formula, which, with the salt itself, has been omitted in the British Pharmacopœia, the valerianate was obtained by double decomposition between quinine hydrochlorate and sodium valerianate, resulting in the production of sodium chloride, which remained in solution, and quinine valerianate, which crystallized.

Quinine valerianate is in "white, or nearly white, pearly, lustrous, triclinic crystals, having a slight odor of valerianic acid, and a bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 5 parts of alcohol; in 40 parts of boiling water, and in 1 part of boiling alcohol. When heated to about 90° C. (194° F.), the salt melts, forming a colorless liquid. At 100° C. (212° F.), it loses its water of crystallization, and also begins to lose valerianic acid. On ignition, it is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral or slightly alkaline to litmus paper. The aqueous solution, when acidulated with sulphuric acid, exhibits a blue fluorescence, and emits the odor of valerianic acid. On treating 10 C.c. of an aqueous solution (about 1 in 1300) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. Quinine Valerianate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*). The aqueous solution of the salt should not be rendered more than slightly turbid by barium chloride test-solution (limit of *sulphate*)." *U. S.*

It may be given in the dose of a grain or two (0·065–0·13 Gm.), repeated several times a day, in cases of *debility* attended with nervous disorder. A combination of Peruvian bark and valerian has long been known as peculiarly efficacious in *hemicrania*. Perhaps quinine valerianate may be used advantageously in the same affection. (*Journ. de Pharm.*, 4e sér., i. 269.)

RESINÆ. Resins.

(RĘ-ŞĪ'NÆ.)

The official *Resins*, with a single exception, constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipitating the resinous matter from the tincture by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it. This set of substances has been much employed by the practitioners styling themselves "eclectics," but with great want of discrimination. They have applied names to these resinous precipitates which, in their proper scientific use, are employed to designate neutral proximate principles of plants, generally representing more or less completely the effects of the plants respectively on the system; as we say *columbin*, *quassin*, *santonin*, etc., themselves proper proximate principles, and representing the virtues, in part at least, of columbo, quassia, santonica, etc., from which they are obtained, and from which they derive their names. By applying similar names to their precipitated resins, such as podophyllin, iridin, cimicifugin, etc., *i.e.*, to the impure resins obtained by precipitating the tinctures of podophyllum, iris versicolor, cimicifuga, etc., they justify the suspicion either that they ignorantly believe them to be in fact the active principles of these medicines respectively, or that, knowing better themselves, they seek to impose such a conviction upon the ignorant. The fact is that the substances thus obtained, and thus named, are impure resins, which may possibly contain more or less of the active principles mixed with them, but are not entitled to names which imply that they are distinct proximate principles themselves.

Resins are solid, brittle, of a smooth and shining fracture, and generally of a yellowish color and semi-transparent. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odor, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0·92 to 1·2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are dissolved by ether and the volatile oils, and generally by alcohol; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With

pure potassa and soda they unite to form soaps, which are soluble in water; and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition; and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.*

RESINA. U. S., Br. Resin. [Colophony.]

(RĔ-SĪ'NĂ.)

"The residue left after distilling off the volatile oil from Turpentine." *U. S.* "The residue left after the distillation of the oil of turpentine from the crude oleo-resin (turpentine) of various species of Pinus." *Br.*

Colophonium, *P. G.;* Rosin, Colophony; Colophane, Résine blanche, Résine jaune, *Fr.;* Kolophonium, Geigenharz, Fichtenharz, *G.;* Ragia di Pino, *It.;* Resina de Pino, *Sp.*

After the distillation of the volatile oil from the turpentine (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony*, but with us is commonly known by the name of *rosin*. It is the RESINA of the U. S. and British Pharmacopœias. It is sometimes called *resina flava*, or *yellow resin*. When this, in a state of fusion, is strongly agitated with water, it acquires a distinct appearance, and is denominated *resina alba*, or *white resin*. The ports from which rosin is shipped are Wilmington, N.C., Charleston, S.C., and Savannah, Ga. The exports of rosin in 1896 amounted to 2,088,518 bbls., valued at $3,952,450; and in 1897 to 2,773,453 bbls., valued at $4,886,543.

Common or *yellow resin*, in its purest state, is beautifully clear and pellucid, but much less so as usually found in commerce. Its color is yellowish brown with a tinge of olive, and more or less dark, according to its purity and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. It is completely liquid at 152·5° C. (306° F.), begins to emit bubbles of gas at 157·5° C. (316° F.), and is decomposed at a red heat. "A transparent, amber-colored substance, hard, brittle, pulverizable; fracture glossy and shallow-conchoidal; odor and taste faintly terebinthinate. Specific gravity 1·070 to 1·080. Soluble in alcohol, ether, and fixed or volatile oils; also in solution of potassium or sodium hydrate." *U. S.* "Translucent, of a light amber color, compact, brittle, pulverizable; fracture shining; odor and taste faintly terebinthinate. It is soluble in *alcohol* (90 per cent.), *ether*, *benzol*, and *carbon bisulphide*, is easily fusible, and burns with a dense yellow flame and much smoke, leaving no appreciable ash." *Br.* The composition of colophony is expressed by the formula $C_{44}H_{62}O_4$, which is the formula ascribed to *abietic anhydride*. Jean, however (*Chem. News*, xxvi. 207), has separated two other resinoid substances in addition to abietic acid. Lewkowitsch (*Chem. Analysis of Oils*, etc., 2d ed., 236) states that colophony also contains varying quantities of unsaponifiable matter.—viz., hydrocarbons due to the partial breaking up of the acid on distilling the pine resin. This may vary from 5 to 9 per cent. in the American colophony. For a paper on abietic acid by Mead and Kremers, see *Proc. A. P. A.*, 1893, 198. By shaking coarsely powdered colophony with dilute alcohol and warming, it is converted into *abietic acid*, $C_{44}H_{64}O_5$, obviously a hydrate of the first. Colophony may be considered, therefore, as abietic acid anhydride, and yields from 80 to 90 per cent. of it under this treatment. Colophony, when boiled with alkaline solutions, forms greasy salts of abietic acid, the so-called resin soaps which are used in admixture with other soaps. As the acid is dibasic, these salts contain two atoms of alkali metal in combination. Colophony, distilled by itself, yields the so-called "rosin oil," of which two fractions are taken separately,—the first that distilling under 360° C. (674° F.), and the second that over 360° C. (674° F.),—and some 31 per cent. of fixed gases.† When distilled with superheated steam, colophony yields benzene and toluene. *Sylvic acid*, formerly considered to be a constituent of colophony, is now regarded as a decomposition product of abietic acid. Similarly *pinic* and *pimaric acids*, announced as found in colophony, are impure products, although the latter acid, or one of the same name, is found in galipot resin. Propionic acid has, according to

* M. Losch recommends the following process for rendering the resins as white as possible. Boil together 5 parts of the resin, 1 of carbonate of potassium or of sodium, and 20 of water, until a perfectly homogeneous mass is obtained; allow this to cool, and pass into it sulphurous acid, which saturates the alkali, and precipitates the resin in white flakes. Finally, wash the precipitate well with water, and dry it. (*Journ. de Pharm.*, Juin, 1856, p. 465.)

† The lighter fraction is known commercially as *rosin essence*, and is, according to Renard (*Jour. Chem. Soc.*, Aug. 1884, p. 843), composed of hydrocarbons, representing almost all series, from the paraffin series to the terpenes, including pentane and hexane, amylene and hexylene, toluene, xylene, and cumene, the tetra- and hexa-hydrides of all three of these, terebenthene and cymene. Several aldehydes and acids of the fatty series, such as isobutyric and valeric, were also recognized. The heavier fraction, or rosin oil in the stricter sense of the word, is composed of polymers of the hydrocarbons C_nH_{2n-2}, which readily resinify by the absorption of oxygen. This accounts for the use of rosin oil as an adulterant of linseed oil in the manufacture of printers' ink.

M. Renard, been obtained in abundance from the tar produced by the destructive distillation of rosin. (*Archiv d. Pharm.*, 1886, p. 939.)

White resin differs from the preceding only in being opaque and of a whitish color. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent. A new and very interesting class of derivatives from colophony or rosin has been prepared by Dr. Eugen Schaal, of Feuerbach, Germany, and introduced into commerce under the name of *ester gums*. These are the *glyceryl*, *methyl*, and *ethyl esters of abietic acid*, made by heating the resin acid and the alcohol under pressure until saponification takes place. The product is then distilled off under reduced pressure. These "ester gums" are now being used to advantage as substitutes for copal, damar, and kauri gums in varnish-making.

Medical Uses. Resin is important as an ingredient of ointments and plasters, but is rarely used internally. It has been given in *chronic enteritis*, five grains of the powder. According to Professor Olmsted, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*A. J. P.*, xxii. 325.)

RESINA COPAIBÆ. U. S. Resin of Copaiba.

(RĔ-ZĪ'NA CŌ-PĀ'Ĭ-BÆ.)

"The residue left after distilling off the volatile oil from Copaiba." *U. S.*

Schweitzer first obtained from copaiba resin *copaivic acid*, which, analyzed by H. Rose, was found to have the formula $C_{20}H_{30}O_2$. When crystallized from alcohol the acid fuses at 116°–117° C. (240·8°–242·6° F.). Another acid, *oxycopaivic*, was obtained by Von Fehling, and still a third, *metacopaivic acid*, by Strauss. The first of these has the formula $C_{20}H_{28}O_3$, and the second $C_{22}H_{34}O_4$. The properties of copaivic acid have been fully treated of under *Copaiba*, page 452, and *Massa Copaibæ*, page 854, which see. It is officially described as "a yellowish or brownish-yellow, brittle resin, having a slight odor and taste of copaiba. Soluble in alcohol, ether, chloroform, carbon disulphide, benzol, or amylic alcohol." *U. S.*

Medical Properties. Bernatzik exhibited nearly four drachms of this resin in five hours, causing violent gastro-intestinal irritation, with vomiting and purging, besides renal disturbance. The resin is eliminated by the urine, and exerts some influence upon the genito-urinary mucous membrane. It is, however, inferior to either the volatile oil or the balsam. The dose is from ten to twenty grains (0·65–1·3 Gm.).

RESINA JALAPÆ. U.S. (Br.) Resin of Jalap.

(RĔ-ZĪ'NA JĂ-LĀ'PÆ.)

Jalapæ Resina, *Br.;* Résine de Jalap, *Fr.;* Jalapenharz, *G.*

"Jalap, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *twenty-five hundred cubic centimeters* [or 84 fluidounces, 256 minims] of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the tincture is reduced to *four hundred grammes* [or 14 ounces av., 48 grains], and add the latter, with constant stirring, to *nine thousand cubic centimeters* [or 304 fluidounces, 155 minims] of Water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of Water. Place it upon a strainer, and, having pressed out the liquid, dry the Resin with a gentle heat, stirring occasionally until the moisture has evaporated." *U. S.*

"Jalap, in No. 40 powder, 8 *ounces* (Imperial) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity;* Distilled Water, *a sufficient quantity*. Digest the Jalap with twice its weight of the Alcohol in a covered vessel, heating gently, for twenty-four hours; transfer to a percolator; when the tincture ceases to pass, continue the percolation with successive portions of the Alcohol until nothing more is dissolved; add to the tincture thus produced *four fluid ounces* (Imp. meas.) or fifty cubic centimetres of the Distilled Water; remove the alcohol by distillation; transfer the residue while hot to an open dish; allow it to become cold; pour

off the supernatant fluid from the resin; wash this two or three times with hot Distilled Water; dry." *Br.*

The two processes probably do not differ very materially in the result; though, if jalap yield anything to alcohol that is insoluble in water besides resin, it will be necessarily found in the British preparation, while that of the U. S. Pharmacopœia will consist of resin almost exclusively. The difference arises from the circumstance that in the Br. process, probably to enable the whole of the alcohol to be saved by distillation, the water for precipitation is added before the spirit is distilled off, while in the U. S. process it is not added until so much of the alcohol has been distilled as to leave only enough to hold the extracted matters in solution. It is obvious, therefore, that the resin of the former contains everything insoluble in water that the alcohol had extracted, while that of the latter contains nothing which water was unable to precipitate from the strong tincture left in the still. "Yellowish-brown, or brown masses or fragments, breaking with a resinous, glossy fracture, translucent at the edges, or a yellowish-gray or yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. Permanent in the air. Its alcoholic solution has a faintly acid reaction. Soluble in alcohol in all proportions; insoluble in carbon disulphide, benzol, and fixed or volatile oils. Not more than about 10 per cent. of it is soluble in ether. On evaporating the ethereal solution, and dissolving the residue in potassium hydrate test-solution, a reddish-brown liquid is formed, from which the resin is reprecipitated by acids. If that portion of Resin of Jalap which remained undissolved by ether be dissolved in potassium hydrate test-solution, the addition of an acid does not precipitate it. Resin of Jalap should not suffer any material loss of weight when heated at 100° C. (212° F.) (absence of *water*). Water triturated with it should neither become colored, nor take up anything soluble from it (absence of *soluble impurities*). On digesting 1 Gm. of Resin of Jalap for about an hour, with frequent agitation, in a glass-stoppered vial, with 10 C.c. of ammonia water, at a temperature of about 80° C. (176° F.), it should yield a solution which does not gelatinize on cooling (absence of *common resin*)." *U. S.* "In dark-brown opaque fragments, translucent at the edges, brittle, breaking with a resinous fracture, readily reduced to a pale-brown powder, sweetish in odor, acrid to the throat, easily soluble in *alcohol* (90 per cent.), insoluble in *oil of turpentine*. The powder yields little or nothing to warm *water*, and not more than 10 per cent. to *ether* (indicating absence of scammony resin and resin of Tampico jalap). A solution in *alcohol* (90 per cent.) is not colored bluish-green by *test-solution of ferric chloride* (absence of guaiacum resin)." *Br.*

The U. S. resin, although pure enough for practical purposes, is still colored. To obtain it colorless, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the instrument. The coloring matter is thus left behind; and the resulting tincture, treated as directed in the process, yields the resin as white as starch. Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum; the former constituting about 70 per cent. It is insoluble in oil of turpentine. (*Squire.*) For its chemical properties, see *Jalapa*. It was at one time supposed that the purgative properties resided chiefly, if not exclusively, in the hard resin; but experiments by Mr. John C. Long appear to prove that the soft is equally energetic. (*A. J. P.*, 1861, p. 489.)

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green color it produces when a few drops of solution of sodium or calcium chloride are added to an alcoholic solution of the suspected resin. (*Journ. de Pharm.*, 3e sér., x. 357.) When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or hydrochloric acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being wholly soluble in ether, while jalap resin is not. (*Neues Repert. für Pharm.*, No. 1, 1854.)

It is now generally believed that the resin of jalap is its sole purgative principle, the gummy extractive being either simply diuretic or wholly inert. To obviate the occasional harshness of the resin, it has been advised to triturate it with milk sugar, potassium sulphate, almond emulsion, or other substance calculated to separate its particles. It may be conveniently made into pill with mucilage or alcohol. (Hasselby, *P. J. Tr.*, 2d ser., vii. 231.) The dose is from two to five grains (0·13–0·33 Gm.).

RESINA PODOPHYLLI. U. S. (Br.) Resin of Podophyllum.

(RĔ-ZĪ'NĂ PŎD-Ō-PHĬL'LĪ.)

Podophylli Resina, *Br.;* Resin of May-Apple; Résine de Podophylle, *Fr.;* Podophyllumharz, *G.*

"Podophyllum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Hydrochloric Acid, *ten cubic centimeters* [or 162 minims]; Alcohol, Water, each, *a sufficient quantity.* Moisten the powder with *four hundred and eighty cubic centimeters* [or 16 fluidounces, 111 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *sixteen hundred cubic centimeters* [or 54 fluidounces, 49 minims] of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the tincture is reduced to a syrupy consistence, and pour it slowly, with constant stirring, into *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, previously cooled to a temperature below 10° C. (50° F.), and mixed with the Hydrochloric Acid. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of cold Water. Spread it, in a thin layer, upon a strainer, and dry the Resin by exposure to the air, in a cool place. Should it coalesce during the drying, or aggregate into lumps having a varnish-like surface, it should be removed, broken in pieces, and rubbed in a mortar. As this is liable to happen during warm weather, Resin of Podophyllum is preferably made during the cold season." *U. S.*

"Podophyllum Rhizome, in No. 40 powder, 1 *pound* (Imperial) or 400 grammes; Alcohol (90 per cent.), 3 *pints* (Imp. meas.) or 1500 cubic centimetres or a sufficient quantity; Distilled Water, Hydrochloric Acid, of each *a sufficient quantity.* Exhaust the Podophyllum with the Alcohol by percolation; place the resulting tincture in a still; recover the greater part of the alcohol; acidulate the Distilled Water with one twenty-fourth of its bulk of Hydrochloric Acid, and slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the acidulated water, constantly stirring; allow the mixture to stand for twenty-four hours to deposit the resin; wash the resin on a filter with Distilled Water, and dry it at a temperature not exceeding 100° F. (37·7° C.)." *Br.*

The British Pharmacopœia, at its 1885 revision, very properly abandoned the use of hydrochloric acid, as it is not necessary if the tincture be evaporated to the consistence of *thick* honey. Hydrochloric acid seems to aid the precipitation when the tincture is not so concentrated. The color and yield of resin of podophyllum may be made to vary by adding alum, acids, or other substances to the water. It darkens if dried with the aid of heat, and its color is indeed no indication whatever of its quality. The average yield of resin is about 4 per cent.

Resin of podophyllum has usually a light-brown color, an acrid bitter taste, and a slight odor of the root. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to Mr. John W. Cadbury, 75 per cent. of the whole (*A. J. P.*, July, 1858, p. 301), according to Mr. Harvey Allen, 80 per cent. (*Ibid.*, May, 1859, p. 206.) "An amorphous powder, varying in color from grayish-white to pale greenish-yellow or yellowish-green, turning darker when exposed to a heat over 35° C. (95° F.); having a slight, peculiar odor, and a peculiar, faintly bitter taste. Permanent in the air. Its alcoholic solution has a faintly acid reaction. Soluble in alcohol in all proportions; ether dissolves 75 to 80 per cent. of it; boiling water dissolves about 80 per cent., and deposits most of it again on cooling, the remaining, clear aqueous solution having a bitter taste, and turning brown on the addition of ferric chloride test-solution. Resin of Podophyllum is also soluble in potassium or sodium hydrate test-solution, forming a deep yellow liquid, which gradually becomes darker, and from which the resin is reprecipitated by acids." *U. S.*

"An amorphous powder, of a bitter taste, varying in color from pale yellow to deep orange-brown; soluble or nearly so in *alcohol* (90 per cent.) and in *solution of ammonia;* precipitated from the former solution by *water*, from the latter by acids. Partly soluble in *ether.* It should not yield more than 1 per cent. of ash upon incineration." *Br.* G. M. Beringer (*A. J. P.*, 1894, 11) obtained different results in the official solubilities by testing a fresh sample. The official resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. The name of *podophyllin*, given to it by the practitioners calling themselves eclectics, who have long been in the habit of using this resin, is inappropriate, and should be abandoned. H. J. Lohmann (*Proc. N. J. Pharm. Assoc.*, 1896, 51) states that the fresh

drug does not yield as large a percentage of resin as the same drug would if tested after being stored for several years; his experiments led him to the conclusion that in the order of value of resin of podophyllum obtained by various methods, that made by precipitation with water alone came first, that made by the U. S. P. process second, and that made by precipitation with solution of alum last, the doses being in the following order: first, one-hundredth grain; second, one-fourth to one-half grain; third, one to one and a half grains.

Resin of podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favorably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It is supposed to be especially cholagogue, and this belief has been confirmed by the experiments of Rutherford. There has been much difference of opinion as to the relative activity of the two resins composing it, some maintaining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Mr. Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. Moreover, this evidence was subsequently confirmed by the experiments of Prof. F. B. Power. (*A. J. P.*, xlvi. 227.) It is asserted by Prof. Power, and confirmed by Prof. Maisch (*Ibid.*, 226), that the purgative principle of podophyllum is soluble in hot water.* The researches of Power (*A. J. P.*, 50, p. 369), Maisch (*P. J. Tr.*, 1880, p. 621), Quereschi (*Ber. Chem. Ges.*, 12, p. 683), and Podwyssotzki have established the fact that podophyllum does not contain berberine or any alkaloid, and that its activity is due to principles present in the resins. (See *Podophyllum.*) Resin of podophyllum is a mixture of the active and inert principles of the root. The dose of the official resin is from one-eighth of a grain to half a grain (0·008–0·03 Gm.). A small proportion of extract of belladonna or hyoscyamus mitigates its irritant action. Care must be used in handling it in quantity, as it is a powerful irritant, frequently producing conjunctivitis.

RESINA SCAMMONII. U. S. (Br.) Resin of Scammony.

(RĔ-ZĪ'NA SCAM-MŌ'NĪ-Ī.)

Scammoniæ Resina, *Br.;* Resina Scammoniæ, *P. G.;* Résine de Scammonée, *Br.;* Scammoniaharz, *G.*

"Scammony, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity.* Digest the Scammony with successive portions of boiling Alcohol until it is exhausted. Mix the tinctures, and reduce the mixture to a syrupy consistence by distilling off the Alcohol. Then add the residue in a thin stream, with active stirring, to *twenty-five hundred cubic centimeters* [or 84 fluidounces, 256 minims] of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Scammony Root, in coarse powder, 8 *ounces* (Imperial) or 150 grammes; Alcohol (90 per cent.), *a sufficient quantity;* Distilled Water, *a sufficient quantity.* Exhaust the Scammony Root with the Alcohol by percolation; place the resulting tincture in a still; recover the greater part of the alcohol; slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the Distilled Water, constantly stirring; allow the mixture to stand for the resin to subside; then wash the resin on a filter with boiling Distilled Water and dry it on a water-bath." *Br.*

The U. S. and British resins, though the former is procured from the gum-resin and the latter from the root of the plant, are nearly identical in their effects. Indeed, the elaborate researches of Professor H. Spirgatis (*A. J. P.*, xlvi. 421) appear to have established the identity of the two products. Mr. A. Hess, however (*Ibid.*, 1875, p. 210), states that the resin obtained from the root contains tannic acid. The advantage of the preparation is that the resin is obtained free from the inert matters with which it is often associated in the scammony of commerce. When pure virgin scammony can be procured, any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown color, with a feeble odor and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow color, and is without odor or taste, but retains its purgative property. "Yellowish-brown or brownish-yellow masses or fragments,

* Under the name of *Podophyllin purissimum* the German chemists have put upon the market that portion of the resin of podophyllum which is soluble in ether. It should be of a pure yellow color, and should not be precipitated from its 50-per-cent. alcoholic solution by the addition of 10 parts of ether.

breaking with a glossy, resinous fracture, translucent at the edges; or a yellowish-white or grayish-white powder, having a faint, peculiar odor, and a slight, peculiar taste. Soluble in alcohol in all proportions; also wholly soluble in ether and in oil of turpentine. Ammonia water and solutions of alkalies dissolve it with the aid of a gentle heat; from these solutions the resin is not reprecipitated by acids." *U. S.* "Its solution in *alcohol* does not give a blue color with *test-solution of ferric chloride*, or with *solution of hydrogen peroxide* (absence of guaiacum resin). *Ether* dissolves it almost entirely (distinction from jalap resin)." *Br.* The Br. resin is in brownish translucent pieces, with a resinous fracture, and a sweetish fragrant odor derived from the root, and wholly different from that of scammony. It cannot, alone, form an emulsion with water. Its tincture does not render the freshly-cut surface of a potato blue.

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test of common rosin or colophony, producing instantaneously with this substance an intense red color, while with the resin of scammony it causes no immediate change. For the tests of guaiac, the reader is referred to that article on p. 674. (See also *A. J. P.*, xxiv. 158.) The presence of other resins may be known by the precipitates yielded when sulphuric acid is added to the alkaline solution, the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Mr. Chas. Bullock has found the resins of scammony, of jalap, and of podophyllum to be insoluble in benzol, thus enabling any resin soluble in this liquid, which may be employed in their sophistication, to be readily detected. (*A. J. P.*, 1862, 114.) When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, undistinguishable from rich milk itself. This is an excellent mode of administration. The resin should always be given either rubbed up with some mild powder or in emulsion. The dose is from four to eight grains (0·26–0·52 Gm.).

RESORCINUM. U. S. Resorcin. [Resorcinol. Metadioxybenzol.]

$C_6H_4(OH)_2$; 109·74. (RĒ-SŎR-CĪ'NŬM.)

"A diatomic phenol. Resorcin should be kept in dark amber-colored vials." *U. S.*

Resorcin—or resorcinol,* as it is sometimes written to indicate its phenol character—is *meta-dioxybenzene*, while pyrocatechin is the *ortho* compound and hydroquinone the *para* compound. Hlasiwetz and Barth first obtained this organic body in 1864 by fusing galbanum resin with potassa; it was subsequently obtained from *sagapenum*, *asafetida*, *ammoniac*, and *gum acroides*. According to Kopp, it is easily and cheaply prepared by the destructive distillation of *brazilin*, or from the wash or mother-waters obtained in its manufacture from Brazil-wood. It is now generally prepared by fusing sodium benzene disulphonate with caustic soda. *Resorcin* is a diatomic phenol, isomeric with *pyrocatechin* and *hydroquinone*. It crystallizes in prismatic crystals of the rhombic system, melting when perfectly pure and dry at 118° C. (244·4° F.), and when less pure at from 111° to 112° C. (231·8°–233·6° F.), distilling at 276° C. (528·8° F.), easily soluble in water, alcohol, and ether, insoluble in chloroform and carbon disulphide. A small quantity treated with fuming sulphuric acid is dissolved, with the production of, first, an orange-yellow, then a greenish-blue, and finally a pure blue color. Bromine water precipitates its aqueous solution, *tribromresorcin* separating in minute crystals. Several of the compounds of resorcin with phthalic anhydride have assumed great technical importance as dye-colors under the names of *fluorescein*, *eosin*, and *uranine*. Its trinitro derivative is *styphnic acid*, $C_6H(OH)_2(NO_2)_3$, which is also formed from many of the gum-resins by the action of nitric acid.†

"Colorless or faintly reddish, needle-shaped crystals or rhombic plates, having a faint, peculiar odor, and a disagreeable, sweetish and afterwards pungent taste. Resorcin acquires a reddish or brownish tint by exposure to light and air. Soluble at 15° C. (59° F.), in 0·6 part of water, and in 0·5 part of alcohol; very soluble in boiling water, or in boiling alcohol; also readily soluble in ether or glycerin; very slightly soluble in chloroform. When heated to a temperature between 110° and 119° C. (230° and 246·2° F.), Resorcin melts, the higher melting point indicating a greater degree of purity. At a higher heat it is completely volatilized. The

* Some confusion exists in connection with the use of the word "resorcinol." The American Association for the Advancement of Science has adopted this name for resorcin; Biélaïew uses (improperly) the word resorcinol for a mixture of equal parts of resorcin and iodoform.

† Resorcin combines with various principles. In this way arise *eucalyptoresorcin*, *caffeoresorcin*, etc. (see *P. J. Tr.*, xxi. 977); also a brown powder said to be composed of resorcin and iodoform which has been commended by Biélaïew (*Sem. Méd.*, 1892) as a stimulant application to foul *ulcers*, in *eczema*, etc. It is very irritant, and usually requires dilution (from 6 to 25 per cent.).

aqueous solution is neutral or only faintly acid to litmus paper. On adding a few drops of ferric chloride test-solution to 10 C.c. of a dilute aqueous solution (1 in 200) of Resorcin, the liquid assumes a bluish-violet color. If 0·1 Gm. of Resorcin be dissolved in 1 C.c. of potassium hydrate test-solution and a drop of chloroform added, the mixture, upon being heated, will assume an intense, crimson color. If a slight excess of hydrochloric acid be then added, the color will change to a pale straw-yellow. On cautiously heating 0·05 Gm. of Resorcin with 0·1 Gm. of tartaric acid and 10 drops of concentrated sulphuric acid, a thick, carmine-red liquid will be formed, becoming pale yellow when diluted with water. A concentrated aqueous solution (1 in 2) of Resorcin should be colorless (absence of *empyreumatic bodies*), and when gently heated should not emit the odor of *phenol*." *U. S.*

Medical Properties and Uses. Resorcin appears in its physiological properties to be allied to carbolic acid. It is distinctly poisonous to the lower organisms, and, according to Martin Cohn (*Inaug. Diss.*, Berlin, 1882) and Dr. Andeer (*Ueber das Resorcin*, Würzburg, 1880; also *Centralbl. für Med. Wissen.*, 1881), a one-per-cent. solution of it is sufficient to arrest for a long time putrefactive changes in the urine, organic infusions, and even animal tissues. Platt, however, states (*Amer. Journ. of the Med. Sci.*, vol. i., 1883) that it is distinctly inferior to carbolic acid as an antiseptic. When given to the lower animals (Dujardin-Beaumetz, *Bull. Thérap.*, ci. 113) it causes tremors, loss of consciousness, and epileptiform convulsions, which, when the dose has been sufficiently large, become more and more violent and associated with marked disturbance of respiration; this function is finally arrested, and death ensues. During the spasms the temperature of the animal is distinctly elevated, but when there is quiet narcosis it may fall much below the norm. The urine becomes olive green deepening into blackish. So far as we know, no case of fatal poisoning in man has been recorded. The largest therapeutic doses produced flushing of the face, with giddiness and buzzing in the ears and some quickening of the breathing and pulse, followed after a time by violent perspiration. Sixty grains caused in man giddiness, violent perspiration with marked anxiety, ending in collapse and unconsciousness. Andeer took about one hundred and fifty grains of resorcin dissolved in a pint of water during fifteen minutes. After disturbance of cerebration and of the special senses, he fell into a condition of collapse, with cold extremities, epileptiform convulsions, opisthotonos, loss of consciousness, and marked irregularity of the respiration. Consciousness did not return for five hours. Dr. Murrell records (*Med. Times and Gaz.*, vol. ii., 1881) a case in which a woman took one hundred and twenty grains of resorcin and immediately felt giddy, had sensation of pins and needles all over her, and a few minutes later became insensible, with closed eyes, clinched hands, groaning, with pallid, blanched lips, dry tongue, normal pupils, insensible conjunctiva, and a temperature of 94° F.; the patellar reflex was entirely gone; the pulse was weak and thready.

The chief action of resorcin is upon the nerve-centres, although, like carbolic acid, it probably affects all highly-organized tissues. The experiments of Dr. Beyer (*Amer. Journ. Med. Sci.*, April, 1886) show that it has a direct action upon the heart. Moderate doses paralyze the sinus and auricles, and very large doses cause immediate diastolic arrest of the whole heart.

As an antipyretic, resorcin has been used by Lichtheim (*Correspondenzbl. f. Schweizer Aerzte*, July, 1880), Murrell, and other clinicians. It is probably capable of acting effectively, but it is inferior to and more dangerous than some of the other antipyretics, and is now employed solely as a topical remedy in diseases of the skin and of the mucous membrane. Dr. Andeer originally recommended it as an antiseptic stimulant application in uterine and vaginal disease, stating that it must be used in the form of an ointment spread upon a tampon, as the injection of a two-per-cent. solution is prone to produce severe uterine contractions. It has been strongly recommended by Hoefer, Lichtheim, Janicke, Fliesburg (see *Therap. Gaz.*, vols. ii. and iii.), and other physicians in the treatment of various gastro-intestinal affections, in which it is believed to do good partly by checking fermentative changes in the contents of the alimentary canal, and partly by a specific action upon the mucous membrane: in this manner it has been employed in *gastric ulcer*, *vomiting*, and *cholera infantum* and other *diarrhœas*. It has been used with alleged good results in inflammations of the upper respiratory passages. Thus, Fliesburg states that in *hay fever* a spray of from thirty to fifty per cent. of resorcin, given two or three times a day, is of the greatest service, and that it is possible to arrest *whooping-cough* by the frequent employment of the spray of from five- to twenty-per-cent. solution. The solution of from one to five per cent. has been employed with alleged excellent results as a local application in *chronic otitis*, *gonorrhœa* and *leucorrhœa*, etc. In *cystitis* the remedy may be administered by the mouth, or applied in weak solution by injection. It is said to be an active parisiticide, and to be

valuable in the treatment of the various skin diseases dependent upon the presence of an animalcule or a fungous growth. Too irritating for acute inflammations of the skin, it is alleged to exert a powerful effect on recent cell-infiltrations, and is certainly valuable in chronic *eczema* where there is much thickening from exudation. It may also be used in *psoriasis*. According to Andeer, resorcin in powder in saturated solution is a feeble caustic, useful in the treatment of *chancres* and of *papilloma*, and even in *diphtheria*. Murrell affirms that he has often given forty grains of resorcin at a dose every four hours without the production of any unpleasant symptoms; but this is probably because he had an impure article. Of pure resorcin the dose may be set down as from two to five grains (0·13–0·32 Gm.). For use upon the mucous membrane the strength of the solution may vary from 1 to 20 per cent. Upon the skin the solution or ointment may vary from 5 to 30 per cent.

RHAMNUS PURSHIANA. U. S. (Br.) Cascara Sagrada.

(RHĂM'NŬS PŬR-SHĮ-Ā'NA.)

"The bark of Rhamnus Purshiana, De Candolle (nat. ord. Rhamnaceæ)." *U. S.* "The dried bark of Rhamnus purshianus, DC." *Br.*

Cascara Sagrada, *Br.;* Sacred Bark; Chittem Bark.

For generic characters, see *Frangula.*

A number of species of Rhamnus have been described as growing in California, but according to the best authority there are only four species,—*R. alnifolia*, *R. crocea*, *R. purshiana*, and *R. californica*. Of these species, *R. alnifolia* is too rare in the Cascara district to be important; whilst the spinescent twigs, the very thick oval or roundish leaves, and the small roundish red fruit of *R. crocea* make it so distinct that it cannot be confounded with the Cascara, whose bark, moreover, its bark does not resemble. On the other hand, *R. californica* appears to be very commonly confounded with the official species by collectors, and to have yielded much of the cascara sagrada bark of commerce. *R. californica* is rare in Northern California, but abundant in the countries lying south and southeasterly; whilst *R. purshiana* is abundant in Northern California, but scarce in the south, so that any bark collected in Northern California is probably genuine. *R. californica* is chiefly distinguished from the official species by its leaves being thin, and when not smooth having a short close pubescence, and the primary veins of the under surface not nearly so numerous, straight, or fine as those of *R. purshiana*. Prof. Rusby thinks that its leaves are especially distinguished by the channel of the midrib of *R. californica* being altogether absent, or shallow, or inconspicuous. Nevertheless the species so run into one another that competent botanists believe them identical.

The *Rhamnus purshiana* is a small tree, attaining at most a height of twenty feet. Its leaves are rather thin, elliptic, for the most part briefly acutely pointed, finely serrated, at the base obtuse, somewhat pubescent beneath, from two to seven inches long and from one to three wide. The rather large flowers are in somewhat umbellate cymes; the sepals five; the minute cucullate petals bifid at the apex. The fruit is black, broadly obovoid, four lines long, three-lobed, and three-seeded. The seeds are convex on the back, with a lateral raphé. It is found in California, extending northward to the British territories.

The *Rhamnus californica*, or *Californian buckthorn* or *California coffee-tree*, yields a bark which is of a dark brown color externally and bright yellow internally, having an intensely bitter taste, with a persistent nauseous after-taste, and very little odor. It is said to be much more distinctly purgative than that of *R. crocea*. The dose of the fluid extract is set down as from one-half to one fluidrachm.

It does not seem possible to distinguish with certainty between the barks of the two species by their macroscopic appearance. The bark of *R. purshiana* is usually more red than is that of *R. californica*, but it may be of a distinctly gray color. The microscopic structure of the two barks is, however, different. The medullary rays in *R. purshiana* are numerous, thin, for a long distance nearly parallel and straight (according to L. E. Sayre, they converge at their outer ends), run nearly three-quarters of the distance through the bark, and are commonly composed of two rows of cells. In *R. californica* the medullary rays are much broader, much shorter, and are composed usually of three or more rows of cells; further, they are crooked and not parallel throughout their course. Again, the zone of resin-spaces is much broader in *R. californica*, and the spaces themselves much larger and more numerous, than in the official species. For further details and elaboration, see paper by Prof. H. H. Rusby, *Proc. A. P. A.*, 1890. According to L. E. Sayre (*A. J. P.*, March, 1897), the powder of the barks can be

distinguished by paying attention to the fact that *R. frangula* contains no stone cells, whilst in *R. californica* and *purshiana* such cells are abundant, occurring in large, irregular groups below the cork and usually outside the region of the bast: *R. purshiana* may also be distinguished from *R. californica* by color-tests. After several days' maceration in dilute alcohol the powder of *R. purshiana* appears of an orange-yellow color, *R. californica* of a purplish color; or if 0·2 Gm. of the powdered bark be placed in a small test-tube, and there be added 2 C.c. of solution of potassa test-solution, *R. californica* will give a blood-red and *R. purshiana* an orange-red color.

The bark of *Rhamnus crocea*, the so-called *Californian mountain holly*, occurs in slightly curved pieces, externally of a dark brown color, internally of a characteristic red delicately streaked with numerous white veins. The odor is somewhat aromatic, the taste warming and not unpleasantly bitter. It is affirmed to be a tonic and mild laxative. The dose of the fluid extract, made according to the ordinary formula, is from one to three fluidrachms.

Properties. Cascara sagrada occurs in commerce in the form of small broken pieces, often more or less flattened out into a somewhat compressed mass, and also as separated quills of varying length and size. The bark is "in quills or curved pieces, about 3 to 10 Cm. long, and about 2 Mm. thick; outer surface brownish-gray and whitish; the young bark having numerous, rather broad, pale-colored warts; inner surface yellowish to light brownish, becoming dark brown by age; smooth or finely striate; fracture short, yellowish, in the inner layer of thick bark somewhat fibrous; inodorous; taste bitter."* *U. S.* The freshly fractured surface is colored red by potash. According to the analysis of Prof. A. B. Prescott (*New Preparations*, Feb. 1879), it contains a very bitter brown resin (which is colored a vivid purple-red by caustic potash); a red resin; a light yellow resin; tannic, malic, and oxalic acids; a neutral crystallizable substance; and a volatile oil.† H. F. Meier and J. Le Roy Webber have pointed out in addition the presence of a ferment, glucose, and ammonia. According to these investigators, to the action of the ferment are attributed the unpleasant results attending the administration of "fresh bark," and "seasoned bark"—*i.e.*, such as has been kept a year or two—owes its valuable properties as a laxative, *free from griping*, to the fact that the ferment has exhausted itself: the laxative properties, they state, reside in the resins, and the tonic effects are due to the crystalline bitter principle. (*A. J. P.*, 1888, 91.) Parke, Davis & Co., the introducers of this remedy, inform us that they always keep the bark two years before using it. Schwabe (*Archiv d. Pharm.*, 226, 569) identified *emodin*, or trioxymethyl-anthraquinone, as present, and stated that it was the active principle. Dohme and Engelhardt (*Proc. A. P. A.*, 1897, 193) have cleared up the matter, and shown the analogy of cascara sagrada with *Rhamnus frangula* by obtaining a glucoside to which they give the name of *purshianin*. This decomposes, yielding emodin and a dextro-rotatory non-fermentable sugar, while the frangulin of buckthorn yields emodin and rhamnose as the sugar. Purshianin forms brown-red needles, melting at 237° C. Dohme and Engelhardt failed to obtain in a pure form (*Proc. A. P. A.*, 1898, 340) the bitter principle of cascara sagrada.

Medical Properties. Cascara sagrada is an excellent laxative for use in *habitual constipation*. It is not to be employed as a purgative when a powerful impression is desired to be made. Its action closely resembles that of *Rhamnus frangula*, but it is probably more powerful and certain in its influence. In many cases of habitual constipation the continued use of the bark seems to produce a permanent influence upon the intestinal tract, so that the glandular and peristaltic actions become of themselves sufficiently active. The best results are sometimes achieved by giving a single dose at bedtime, but some cases in which this method does not work well are much benefited by giving a smaller quantity after meals. The dose of the fluid extract may be set down at from ten to thirty drops. The solid extract is recommended in doses of from two to eight grains, very advantageously combined with strychnine or belladonna.

* The following elaborate microscopic description of cascara sagrada is abbreviated from that of Dr. J. Moeller. (*A. J. P.*, Sept. 1882, 462.) The corky layer is about 0·045 Mm. thick, and consists of 8 or 12 rows, somewhat flattened, rather thick-walled, but not sclerotic cells. The parenchyma of the primary bark contains numerous groups of crystals, and scattered groups of roundish stone cells, with very thick walls, and accompanied by single rhombohedric crystals; it is free from secondary cork. The inner bark consists of medullary rays composed of two or three rows of thin-walled, somewhat radially elongated cells, and of broader bast-rays in which the parenchyma cells are coarsely dotted upon the radial and horizontal walls, and loosely united in a tangential direction; the bast-fibres form alternate groups of two or three rows, extending into few bast-rays, and are surrounded by crystal cells. The medullary parenchyma contains a crummy, lemon-yellow substance, which dissolves in water with a yellow color, and in cold potassa solution with a dingy red color.

† The bark of *R. wightii*, which is sold in the Indian bazaars, has been chemically investigated by Mr. David Hooper and found to contain substances similar to those contained in *R. purshiana*. (See *P. J. Tr.*, Feb. 18, 1888.)

RHEUM. U. S. (Br.) Rhubarb.

(RHĒ'ŬM.)

"The root of Rheum officinale, Baillon (nat. ord. Polygonaceæ)." *U. S.* "The erect rhizome or so-called root of Rheum palmatum, Linn.; Rheum officinale, Baill.; and probably other species; collected in China and Thibet, deprived of more or less of its cortex, and dried." *Br.*

Rhei Radix, *Br.;* Rhubarb Root; Rhabarbarum; Rhubarbe, *Fr.;* Rhabarber, *G.;* Rabarbaro, *It.;* Ruibarbo, *Sp.;* Hainoung, *Chin.;* Schara-modo, *Thibet.*

Notwithstanding the length of time that rhubarb has been in use, it has not yet been determined from what precise plant the Asiatic drug is derived; the remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade is guarded, having prevented accurate information.*

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical title *Rheum*, were applied by the ancients to a root which came from beyond the Bosporus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of the *Rheum rhaponticum*, growing on the banks of the Caspian Sea and the Volga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not till the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species affording the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum rhabarbarum*, a title which has since given way to *Rheum undulatum*. Subsequently, Kaau-Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant producing the root sold by him. These, having been planted, yielded two species of Rheum, *R. undulatum*, and another which Linnæus named *R. palmatum*. Seeds transmitted by Dr. Mounsey from St. Petersburg to Dr. Hope, and planted in the botanic garden at Edinburgh, produced the latter species; and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described in 1767 by the younger Linnæus, two years after the appearance of Dr. Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favor of *R. palmatum* and *R. undulatum*. Colonel Przewalski has recently reasserted from personal observation that *R. palmatum* produces rhubarb; but the specimens of the root which he brought to St. Petersburg are stated by Prof. Dragendorff to be essentially different from true rhubarb. Claims have also been made from time to time for various other species of Rheum as sources of the drug. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape; and the description he received of them corresponded more closely with those of *R. compactum* than of any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg as those of the true Tartarian rhubarb. Dr. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya Mountains and the highlands of Tartary. These produced a species not previously described, which Dr. Wallich named *R. emodi*, from the native title of the plant. It is the *R. australe* of Mr. Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the official rhubarb. In 1867, French missionaries in Southeastern Thibet forwarded to Dr. Soubeiran, of Paris, live specimens of a plant which they asserted to yield the true rhubarb; and Baillon subsequently described the flowering plant under the name of *R. officinale*. Its root resembles the true rhubarb, but the most careful cultivation has failed to obtain an identical product,† and it cannot yet be considered as settled how far the commercial drug is obtained from it.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous flowers, resembling those of the Rumex or dock. There is

* Rhubarb is prone to be attacked during storage by the caterpillar of a small grayish-white moth, whose species does not seem to have been determined. According to the experiments of Sawer and Ferguson, rhubarb which has been attacked is best treated on a large scale by a combination of heat and exposure to the vapor of sulphur. Insect-powder had no effect upon the worms. For details of method, see *P. J. Tr.*, xx., 1889.

† Senier found that, as raised in England, the root of *R. officinale* yielded less than half the percentage of extract obtained from the East Indian drug. In ten-grain doses the extract was decidedly cathartic.

some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids; and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. Lindley states that *R. rhaponticum*, *R. hybridum*, and *R. compactum*, and their hybrids, are the common garden rhubarbs.*

R. officinale. Baillon—*B. & T.* 213—is described in the *Pharmacographia* "as a perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars: the leaves spring from a distinct crown rising some inches above the surface of the ground; they have a subcylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short erect hairs. The lamina, the outline of which is orbicular, cordate at base, is shortly 5- to 7-lobed, with the lobes coarsely and irregularly dentate; it attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display before expanding the peculiar metallic red hue of copper."

Besides the species already mentioned, *R. leucorrhizum*, growing in the Kirgheez desert in Tartary, *R. capsicum*, from the Altai Mountains, *R. webbianum*, *R. speciforme*, and *R. moorcraftianum*, natives of the Himalaya Mountains, and *R. crassinervium* and *R. hybridum*, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives or possess properties more or less analogous to those of official rhubarb, though they have not entered into general commerce. In Java, the root of an indigenous species is used as a purgative. According to the analysis of J. H. Schmidt, it contains more chrysophan and emodin, and less chrysophanic and rheotannic acids, than does the official drug.†

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Nor, and is said to be cultivated in the neighboring Chinese province of Shen-see, and in that of Se-chuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb are exclusively derived; but the root is also collected in Bootan and Thibet, on the north of the Himalaya Mountains; and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. It is stated by Mr. Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state,

* The following descriptions are from the *Flora Medica* of Dr. Lindley:

Rheum palmatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Carson, *Illust. of Med. Bot.* ii. 22, pl. 69; *B. & T.* 214. "Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull green, not wavy, but uneven and very much wrinkled on the upper side, hardly scabrous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forward beyond it. Petiole pale green, marked with short purple lines, terete, obscurely channelled quite at the upper end. Flowering stems taller than those of any other species."

R. undulatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 357; Woodv. *Med. Bot.*, 3d ed., v. 81. "Leaves oval, obtuse, extremely wavy, deep green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, scabrous at the edge; sinus open, wedge-shape, with the lower lobes of the leaves turned upwards. Petiole downy, blood-red, semi-cylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end." This is a native of Siberia, and probably of Tartary and China. It was cultivated by the Russian government as the true rhubarb plant; but the culture has been abandoned. It contributes to the rhubarb produced in France.

R. compactum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Carson, *Illust. of Med. Bot.* ii. 24, pl. 71. "Leaves heart-shaped, obtuse, very wavy, deep green, of a thick texture, scabrous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by the parenchyma. Petiole green, hardly tinged with red except at the base, semi-cylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end." This plant is said to be a native of Tartary and China. It is one of the garden rhubarbs, and has been cultivated in France for its root.

R. australe. Don. *Prod. Flor. Nepal.* p. 75.—*R. emodi*. Wallich; Lindley, *Flor. Med.* p. 354; Carson, *Illust. of Med. Bot.* ii. 24, pl. 70. "Leaves cornate, acute, dull green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped but diverging at an obtuse angle, with the lobes nearly turned upwards. Petioles very rough, rounded-angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end." The root of this species was at one time conjectured to be the source of official Asiatic rhubarb, but has been found to have scarcely any resemblance to it. The plant has been cultivated both in Europe and in this country, and its petioles answer well for tarts, etc.

R. rhaponticum. Willd. *Sp. Plant.* ii. 488; Lindley, *Flor. Med.* p. 357; Loudon's *Encyc. of Plants*, p. 335. "Leaves roundish-ovate, cordate, obtuse, pale green, but little wavy, very concave, even, very slightly downy on the under side, especially near the edge, and on the edge itself; scabrous at the margin; sinus quite open, large, and cuneate. Petiole depressed, channelled on the upper side, with the edges regularly rounded off, pale green, striated, scarcely scabrous. Panicles very compact and short, always rounded at the ends, and never lax as in the other garden species. Flowering stem about three feet high." The Rhapontic rhubarb grows upon the banks of the Caspian Sea, in the deserts between the Volga and the Ural, and in Siberia. It is said also to grow upon the borders of the Euxine. It is cultivated as a garden plant in Europe and in this country; and the root is produced for sale both in France and in England.

† According to Dr. Aitchison (*Nature*, July 9, 1885), a rhubarb plant has been found in Northern Afghanistan in which there are usually only three enormous root leaves four feet long and five feet broad, lying flat upon the ground. The fruit is large and of a brilliant scarlet. The root is said to possess purgative properties, but the fruit is preferred, and is given in the form of a decoction.

that it is not cultivated by the Tartars, but springs up spontaneously, in tufts, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection till it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry: according to Mr. Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Bootan the roots are hung up in a kind of drying-room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root; and Sievers states that a year sometimes elapses from the period of its collection before it is ready for exportation. A large proportion of its weight is lost in drying, according to some accounts four-fifths, according to others not less than seven-eighths. It is probably in order to favor the drying that the bark is removed. The trade in rhubarb is said to have formerly centred in the Chinese town of Si-nin, where a Bucharian company or family was established which possessed a monopoly of this trade in consideration of a tribute paid to the government. At present rhubarb is chiefly purchased for the European trade at the town of Hankow, on the upper Yang-tse, the yearly export reaching, it is said, over 5000 peculs (pecul = 133·33 lbs.). There were formerly two varieties of Asiatic rhubarb, the Russian and the Chinese, but at present little or no rhubarb finds its way overland to Europe. As long back as 1687, the Russian government subjected the export of rhubarb from China into Russia to official surveillance, and finally monopolized the trade entirely. At Kiakhta a very rigorous inspection of the drug was enforced, the selected pieces being finally sewed into linen sacks pitched and coated with hide. All the pieces which did not pass examination were committed to the flames; and the remainder was sent to St. Petersburg. This variety was sometimes called *Turkey rhubarb*, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Anatolia. The circumstance of the identity of the Russian and Turkey rhubarb, and its decided difference from the Chinese, would appear to indicate a distinct origin for the two varieties. Inferior parcels of the root, which could not pass the inspection of the Russian authorities, were said to enter Russia by Tashkend, and to be known to the druggists of that country by the name of *Tashkend rhubarb*. As Russian rhubarb no longer occurs in commerce, the description of it is given in a foot-note.*

Chinese Rhubarb (*India Rhubarb*, *Rheum Sinense* vel *Indicum*) is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow color externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces have a rather close and compact texture, and, when broken, present a ragged uneven surface, variegated with intermingled shades of dull red, yellowish, and white, which are sometimes diversified or interrupted by darker colors, and especially marked with dark lines so arranged as to form an internal ring of star-like spots. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process; and portions of the suspending cord are not unfrequently found remaining in the holes. According to Mr. Elborne (*P. J. Tr.*, xv. 497), Chinese rhubarb is really divided into two varieties, which are respectively the product of *R. palmatum* and *R. officinale:* the first variety has a red-grained fracture with white lattice-work veins, whilst the second variety has a longitudinal ramification of white veins with

* The pieces of Russian rhubarb are irregular and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They have a cleaner and fresher appearance than the Chinese, and their color both internally and externally, though of the same general character, is somewhat more lively. They are less compact and heavy, and are cut with less facility, owing to their giving way before the knife. Another distinction is the character of the perforations, which in the Russian rhubarb are large, frequently reaching only to the centre, and evidently made for the purpose of inspection, while in the Chinese they are small, penetrate completely through the pieces, and were intended for the passage of a suspending cord. The taste and smell of the former closely resemble those of the latter, except that the Russian is rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the color of the powder in this variety is a bright yellow, without the brownish tinge exhibited by the Chinese. When thin slices, previously boiled in water, are examined by the microscope, they exhibit numerous clusters of minute crystals of calcium oxalate. Mr. Quekett found between 35 and 40 grains of them in 100 grains of the root. They are observed in both Russian and Chinese rhubarb. For further information as to the varieties of Russian rhubarb, see *A. J. P.*, 1867, p. 212, or abstract in 14th edition U. S. D.

a black-grained fracture. Chinese rhubarb has a peculiar somewhat aromatic smell, and a bitter, astringent taste, is gritty when chewed, imparts a yellow color to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet color. Like all the other varieties of rhubarb, this is liable to be attacked by worms; and in almost every large parcel pieces may be found which have suffered from this cause.*

It is this especial variety of rhubarb which is recognized by the U. S. P., in which it is described as "in cylindrical, conical or flattish segments, deprived of the dark brown, corky layer, smoothish or somewhat wrinkled, externally covered with a bright yellowish-brown powder, marked with white, elongated meshes, containing a white, rather spongy tissue, and a number of short, reddish-brown or brownish-yellow striæ; compact, hard; fracture uneven; internally white, with numerous red, irregularly-curved and interrupted medullary rays, which are radially parallel only near the cambium line; odor somewhat peculiar, aromatic; taste bitter, somewhat astringent. When chewed, Rhubarb feels gritty between the teeth, and imparts a yellow color to the saliva. Rhubarb which is very porous, or has a prominently mucilaginous taste, or is of a dark brown color internally, should be rejected."

European Rhubarb. In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years; and considerable quantities of the root were at one time brought into the market. At present it appears not to be imported.

English Rhubarb. This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The pieces were of various shape and size, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. In the other, the so-called *stick rhubarb*, the pieces were somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. English rhubarb (from *Rheum rhaponticum*) is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling, the pinkish lines being arranged like rays from the centre towards the circumference. The "star-like spots" are either wanting or very few and scattered. The powder also has a deeper reddish tint. The odor is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous, with little bitterness; and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colors the saliva. Few crystals of calcium oxalate are discoverable by means of the microscope. At present about 12,000 pounds of English rhubarb are produced annually. Much of this is obtained from *R. officinale*, and is put on the market in flat, concave, and convex pieces weighing from three to four ounces each. Externally the convex surface has deep longitudinal furrows and a longitudinal ramification of conspicuous veins, giving rise to an appearance of net-vein markings. In the centre of the concave surface is a small hole similar to that formerly seen in Russian rhubarb. On the inner surface the stellate markings resemble very closely those found in the East Indian rhubarb. The fracture of this form is not red, but shows a whitish parenchymatous tissue with blackish veins. The roots are distinctly gritty when chewed. When rapidly grown in rich soil, English rhubarb is lighter, more spongy, and less active than when slowly grown without high cultivation. It is probable that the powder is used to adulterate that of true Asiatic rhubarb.

French Rhubarb. Rhapontic Rhubarb. Crimea Rhubarb. The rhubarb produced in France is, according to Guibourt, chiefly from *R. rhaponticum*, *R. undulatum*, and *R. compactum*, that of *R. palmatum*, which most closely resembles the Asiatic, having been found to degenerate so

* In former editions of this work a variety of rhubarb imported from Canton has been noticed, which was evidently prepared, before leaving China, so as to resemble the Russian, having an angular surface as if pared with a knife. The pieces were obviously selected with great care, as they were remarkably free from defects. But in most of those which came under our notice the small penetrating hole was observable which characterizes the Chinese rhubarb, though it had in some instances been filled with the powdered root, so as in some measure to conceal it. Besides, the colors were not quite so bright as those of Russian rhubarb. This is undoubtedly the variety described by Pereira, under a distinct head, as the *Dutch-trimmed* or *Batavian rhubarb*, and considered by him as probably Bucharian or Russian rhubarb of inferior quality, sent by the way of Canton. A sufficient proof, we think, that this is not the case is the presence in most pieces of the small penetrating hole, occasionally filled with the remains of the cord, and in some pieces almost shaved away in the paring process. We have never seen such a hole in any piece of true Russian rhubarb, which does not appear to be strung up like the Chinese when dried.

Under the title of *Canton stick rhubarb*, Pereira describes a variety of which small quantities have been imported from Canton into London. It closely resembles the English stick rhubarb, and is supposed to be derived from the branches of the root of the plant which yields the true Chinese rhubarb.

much as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighborhood of L'Orient, in the department of Morbihan; and the spot where it grows has, from this circumstance, received the name of *Rheumpole*. Two kinds were described by Guibourt, both under the name of *Rhapontic root*,*—one proceeding from the *R. rhapontic-um*, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole; but, according to the *Pharmacographia*, the cultivation in France has been almost entirely abandoned.†

Choice of Rhubarb. In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively color, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odor decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb is often powdered, and colored yellow with turmeric; and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose.‡ Powdered rhubarb should contain numerous roundish starch granules, about ·026 Mm. in diameter, large associated calcium oxalate crystals, and small, somewhat stellate, chrysophanic acid crystals, besides parenchymatous cells, pitted vessels, and other ordinary débris of root tissue. §

Chemical Properties. Rhubarb yields all its activity to water and alcohol. The infusion is of a dark reddish-yellow color, with the taste and odor of rhubarb; and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are impaired. The first examination of rhubarb yielding results of value was that of Schlossberger and Döpping. Besides extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate, and various inorganic salts, they discovered three coloring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly so in water. Two of these were uncrystallizable, and denominated *brown resin* and *red resin*, or *phæoretin* and *erythroretin;* the other, crystallizable in granular crystals, and identical with *chrysophanic acid*, previously discovered by Rochleder and Heldt in the yellow lichen, or *Parmelia parietina* of Sprengel. Chrysophanic acid crystallizes in golden-yellow needles or plates melting at 102° C., and is soluble in ether, alcohol, or benzene. Alkalies also dissolve it, forming fine dark red solutions. Its formula is $C_{15}H_{10}O_4$, and it is now recognized as a derivative of anthracene, $C_{14}H_{10}$, and as closely related to alizarine, $C_{14}H_8O_4$. It bears to methyl-anthracene, $C_{14}H_9(CH_3)$, the same relation that alizarine bears to anthracene. Hence, on distilling it with zinc dust, methyl-anthracene is formed from it by reduction. (See *Chrysarobinum*.)

* The *rhapontic root* differs in section from true rhubarb by its distinctly radiated structure, unbroken by the peculiar arrangement (star-like spots) of the vascular tissue which occurs in true rhubarb.

† Besides the varieties of rhubarb above described, others are noticed by writers. Pallas speaks of a *white rhubarb*, brought to Kiakhta by the Bucharian merchants who conveyed to that place the drug for Russian commerce. It was white as milk, of a sweet taste, and equal to the best rhubarb in quality. It was supposed to be the product of *R. leucorrhizum*. At present, however, it is unknown in St. Petersburg. The *Himalaya rhubarb* is produced by *R. australe*, and other species mentioned in the text as growing in the Himalaya Mountains. According to Dr. Royle, it makes its way to the lower countries in Hindostan, where it sells for one-tenth of the price of the best rhubarb. Mr. Twining tried it in the Hospital at Calcutta, and found it superior as a tonic and astringent to Russian rhubarb, and nearly equal to it in purgative power. A variety known in Russia as *Bucharian rhubarb*, differing from the variety which we call Russian, and which is known in Russia as Chinese rhubarb, is imported into that country from Tartary, and reaches St. Petersburg by Nizhnee-Novgorod. Parcels of it are said also to reach Vienna, by the way of Brody in Galicia. Still another variety is that called *Siberian rhubarb*, which is known in Russia by the name of *Siberian Rhapontic root*. As these are inferior kinds, and probably never reach our markets, we have not thought it necessary to discuss them in detail. For further information, see *A. J. P.* (xviii. 63 and 123).

‡ It has been stated by Dr. Boni that Chinese rhubarb yields from 20 to 25 per cent. of ash, the European rhubarb from 8 to 11 per cent., the difference being due to the excess of calcium oxalate in the Chinese rhubarb. Kremel, however, finds that the amount of ash in different species of rhubarb fluctuates too greatly to be of practical value in the determination of the source, even the Chinese root varying between 10 and 28 per cent.

§ The powdered rhapontic root seems microscopically indistinguishable from powdered rhubarb; but, according to M. E. Billot, rhapontic root, even when used to adulterate powdered rhubarb, may be detected as follows. On a little of the suspected powder, upon a plate, let fall two or three drops of oil of anise, oil of fennel, or other essential oil; then add magnesia, and rub the mixture well for three or four minutes. If the powder be pure, it will remain yellow; but if it contain the smallest quantity of the French rhapontic root, it will assume a reddish tint, varying from a salmon to a bright rose color, according to the quantity of the impurity present. (See *A. J. P.*, May, 1860, 224.) The *Rumex hymenosalpus*, which is said to be used as an adulterant of powdered rhubarb, according to L. E. Sayre, may be detected by the character of the starch granules, which are long and slender, with a branching hilum extending along their greater diameter.

De La Rue and Müller (*Journ. Chem. Soc.*, x. 298) extracted from rhubarb an allied substance, *emodin*, which crystallizes in orange-colored prisms. (See p. 140; also *Emodin*, PART II.) Its formula is $C_{15}H_{10}O_5$, and it is a trioxy-methyl-anthraquinone. The relations of both this compound and chrysophanic acid to alizarine and anthracene will be better shown by writing their molecular formulas, as follows:

$\underset{\text{Anthracene.}}{C_{14}H_{10}}$. $\underset{\text{Alizarine.}}{C_{14}H_6(OH)_2O_2}$. $\underset{\text{Chrysophanic acid.}}{C_{14}H_5(CH_3)(OH)_2O_2}$. $\underset{\text{Emodin.}}{C_{14}H_4(CH_3)(OH)_3O_2}$.

Kubli (*Pharm. Zeitschr. für Russland*, 6, p. 603) has obtained results both confirmatory and explanatory of those already given. He finds a glucoside, *chrysophan*, $C_{27}H_{30}O_{14}$, which, under the influence of dilute acids or ferments, splits up into chrysophanic acid and sugar, according to the reaction $C_{27}H_{30}O_{14} + 2H_2O = C_{15}H_{10}O_4 + 2C_6H_{12}O_6$; also a characteristic tannic acid, *rheo-tannic acid*, $C_{26}H_{26}O_{14}$, which is decomposed by dilute acids into *rheumic acid*, $C_{20}H_{16}O_9$, and sugar. Chrysophan is a yellowish powder, abundantly present in rhubarb, soluble in water or alcohol, not in ether; rheo-tannic acid is a reddish-brown powder, sparingly soluble in cold water. Kubli finds further a colorless neutral compound, sparingly soluble in hot water, of the formula $C_{10}H_{12}O_4$, which he does not name. He states that chrysophanic acid is not found in rhubarb, but is produced when the root is digested in water through the breaking up of the glucoside *chrysophan*, probably under the action of a ferment. This ferment he believes to be soluble in water, but insoluble in alcohol, and that on this account an alcoholic extract of the root can be evaporated without the formation of chrysophanic acid. On the other hand, it is to the presence of this ferment that he attributes the progressive deposition of chrysophanic acid from an extract of rhubarb prepared with diluted alcohol. (*Pharm. Zeit. f. Russl.*, xxiv. 193.) Dr. O. Hesse (*Proc. A. P. A.*, 1896, 549) finds, in addition to chrysophanic acid, $C_{15}H_8O_2(OH)_2$, and emodin, $C_{15}H_7O_2(OH)_3$, a third crystalline principle, which he names *rhein*, and ascribes to it the formula $C_{15}H_6O_2(OH)_4$. Hesse calls attention to the relation these formulas bear to one another. Rhein forms microscopic yellowish-brown scales, is insoluble in water, ether, and benzene, but sparingly soluble in alcohol. It dissolves readily in aqueous solutions of the alkalies and alkaline carbonates, forming deep purple-red solutions. Hesse also finds an amorphous resinous substance, upon which, he states, the entire activity of rhubarb depends. Dragendorff states that from 11 to 17 per cent. of arabic acid and pectose are present in rhubarb.

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odor to a volatile oil; but this has not been isolated. The calcium oxalate is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Quekett found between 35 and 40 per cent.; while Brandes obtained only 11, Schrader only 4·5 parts in the hundred, and Dragendorff, in five samples analyzed, from 1·2 to 5·6 per cent. Little or no difference of composition has been found between the Russian and the Chinese rhubarb. The European contains but a small proportion of calcium oxalate, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapor of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other coloring principles. It yields precipitates with gelatin, most of the acids, ferric salts, lead acetate, mercurous nitrate, silver nitrate, stannous chloride, lime water, and solutions of quinine. Nitric acid occasions at first a turbidness, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.*

Medical Properties and Uses. The medical properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power; the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic, invigorating, in small doses, the process of digestion. It is not probable that these properties reside in a single proximate principle; and, as rhubarb owes its chief value to their combination, it is not to be expected that chemical analysis will be productive of the same practical advantages in this as in some other medicines, the virtues of which are concentrated in one ingredient. In its purgative operation rhubarb

* For a method of detecting the presence of turmeric in powdered rhubarb by the influence of chloroform on the coloring principles of each of these substances, and of distinguishing through the same agency between the true Chinese rhubarb and that of European origin, the reader is referred to a paper, by Mr. W. L. Howie, contained in *A. J. P.* (Jan. 1874, 16), from *P. J. Tr.* (Nov. 15, 1873); see also *P. J. Tr.*, 1898, 126.

is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory function. It sometimes occasions griping. Its coloring principle is absorbed, and may be detected in the urine. By its long-continued use the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow color to the alvine discharges. The conditions of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled, or the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a rule, is preferable to all others. Hence its use in *dyspepsia* attended with constipation, in *diarrhœa* when purging is indicated, in the secondary stages of *cholera infantum*, in *chronic dysentery*, and, indeed, whenever mild purgation is needed in an enfeebled subject. Magnesia is often an excellent associate in disorders of the stomach and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the associated substance. A mixture of calomel and rhubarb is a brisk and powerful cathartic, often used at the commencement of *bilious fevers*. As a rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

The dose of rhubarb as a purgative is from twenty to thirty grains (1·3–1·95 Gm.), as a laxative and stomachic from five to ten grains (0·33–0·65 Gm.). European rhubarb must be given in double or treble the dose to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup, tincture, and fluid extract are also useful preparations. They are all official.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. When so treated it is termed *torrefied rhubarb*. This mode of treatment has been sometimes resorted to in cases of diarrhœa. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface; and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

RHŒADOS PETALA. Br. Red Poppy Petals.

(RHŒ'Ą-DŎS PĔT'Ą-LĄ—rē'ą-dŏs.)

"The fresh petals of Papaver Rhœas, Linn." *Br.*

Flores Rhœados, *P. G.;* Corn Poppy, Corn Rose; Pavot rouge, Coquelicot, *Fr.;* Wilder Mohn, Klapperrose, Klatschrosen, *G.;* Rosolaccio, *It.;* Amapola, *Sp.*

Papaver rhœas. Willd. *Sp. Plant.* ii. 1146; *B. & T.* 19. The *red* or *corn poppy* is distinguished by its hairy stem, which is branched, and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet color of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. M. Filhol has shown that the extract contains morphine, but in a proportion exceedingly minute compared with that in which it exists in opium. (*Journ. de Pharm.*, ii. 513.) The petals are the official portion. They have a narcotic smell, and a mucilaginous, slightly bitter taste. By drying, they lose their odor, and assume a violet-red color. Chevallier believed that he had detected a very minute proportion of morphine in an extract obtained from them; but Prof. Attfield seems to have determined satisfactorily the non-existence of morphine in the petals, having sought this alkaloid by three different processes, using a pound of the petals in each experiment, and failed to detect the least evidence of its presence. (*P. J. Tr.*, Oct. 1873, p. 291.) Their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet color, which they communicate to water, than for their medical virtues. According to Leo Meier, the coloring principles of the flowers are two acids, which he denominates *rhœadic* and *papaveric acids*. (See *A. J. P.*, xviii. 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections, but is now little esteemed except for its color.

An alkaloid has been discovered in this species of poppy by O. Hesse, who proposes to name it *rhœadine*. It seems to pervade all parts of the plant, from which, as the first step in its preparation, a watery extract is prepared. This is treated with sodium carbonate, and re-

peatedly agitated with ether; the ethereal liquid is shaken with a solution of sodium bitartrate; and the mixture is precipitated by ammonia. The precipitate is washed with cold water, dried, and boiled with alcohol, by which coloring matter and another alkaloid in small quantity, probably thebaine, are removed. The residue, consisting mainly of rhœadine, is purified by combining it with acetic acid, treating with animal charcoal, and precipitating with ammonia. The alkaloid is in small white prismatic crystals, tasteless, fusible at 232·2° C. (450° F.), becoming brown at the same temperature and partially subliming. It is almost insoluble in water, alcohol, ether, chloroform, benzol, ammonia, solution of sodium carbonate, and lime water, but is dissolved by dilute acids, which produce colorless solutions. Its composition is represented by the formula $C_{21}H_{21}NO_6$. It does not appear to be poisonous. Hydrochloric and sulphuric acids, moderately concentrated, decompose and dissolve it, with the production of a purple color, which disappears under the action of the alkalies, but is restored by acids. One part of the alkaloid so treated produces a purple color with 10,000 parts of water, rose color with 20,000 parts, and a perceptible redness with 800,000 parts. This change is dependent upon the liberation from the rhœadine of a red coloring matter, while the isomeric *rhœagenine* remains. This forms small white tasteless prisms, which fuse at 223° C. and do not sublime, but are decomposed at higher temperatures. This is a very delicate test, by means of which the alkaloid may be detected in all parts of *Papaver rhœas*, in the ripe capsules of the opium poppy, and in opium itself. It is said also to exist in Merck's porphyroxine. (*A. J. P.*, 1867, p. 122.) According to Hesse, the milky juice also contains *meconic acid*.

RHUS GLABRA. U. S. Rhus Glabra.

(RHŬS GLĀ′BRA.)

"The fruit of Rhus glabra, Linné (nat. ord. Anacardieæ)." *U. S.*

Rhus Glabrum, *U. S.* 1870; Sumach; Sumac, *Fr.*; Sumach, *G.*

Rhus glabra. L. *Sp. Pl.* (1753) 265; Willd. *Sp. Plant.* i. 1478. This species of Rhus, called variously *smooth sumach*, *Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet or more in height, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth, light gray, or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their color changes to a beautiful red. The flowers are greenish red, and disposed in large, erect, terminal compound thyrses. The fruit is in clusters of small crimson berries, which are officially described as "subglobular, about 3 Mm. [⅛ inch] in diameter, drupaceous, crimson, densely hairy, containing a roundish-oblong, smooth putamen; inodorous; taste acidulous." *U. S.*

The shrub is found in Canada and almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are largely used, especially the leaves, in tanning leather and in dyeing. The sumach for the manufacture of extract for tanners' use is largely cultivated in Virginia, where the annual crop reaches from 7000 to 8000 tons, and is collected at any time between the first of July and the appearance of frost. Mr. W. J. Watson found, in the bark of the root, albumen, gum, starch, tannic and gallic acids, caoutchouc, resin, coloring matter, and evidences of volatile oil. (*A. J. P.*, xxv. 194.) Excrescences are produced under the leaves resembling galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Dr. Walters, of New York, who thought them in every respect preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States. From the experiments of Dr. Stenhouse, it appears that the tannic acid of sumach is identical with that of galls, being, like it, resolved, under the influence of sulphuric acid, into glucose and gallic acid; and this change is supposed to take place spontaneously in sumach when long kept. (*Ibid.*, xxxiv. 252.)

The percentage of tannin in Virginia sumach rises at times as high as 27 per cent., but falls a few per cent. below this as the season advances. Samples of leaves gathered along the Mississippi near Dubuque, Iowa, in July and August, yielded 16·36 per cent. and 15·75 per cent. respectively. (*A. J. P.*, 1888, p. 389). The proportion of tannic acid in the European sumach falls from 6 to 8 per cent. below the percentage of the Virginia sumach, yet the European is much preferred by tanners and dyers. By using Sicilian sumach it is possible to make the finer white leathers so much used for gloves and fancy shoes; while by the employment of the American

product the leather has a disagreeable yellow color, apparently due to a coloring matter, which, according to Loewe, consists of quercitrin and quercetin, and exists in larger quantity in the American than in the Sicilian drug. Enormous quantities of a dark-red, semi-fluid, bitter, astringent extract are prepared in Virginia from sumach, and used both in America and in Europe. It is said to contain from 25 to 30 per cent. of tannin.

Henry Trimble collected some galls from the leaves of *R. glabra* and found that they contained 61·70 per cent. of tannin, reckoned on the weight of the air-dried galls, or 70·90 per cent. of the weight of absolutely dry material. (*A. J. P.*, 1890, p. 564.)

The berries have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Mr. Cozzens, of New York, the malic acid is contained in the pubescence which covers their surface, as when it is washed away by warm water the berries are wholly free from acidity. Prof. W. B. Rogers found the acid to be combined with lime,* as acid calcium malate. Mr. W. J. Watson ascertained that free malic acid and acid calcium malate coexist in the berries, which contain also, upon the same authority, tannic and gallic acids, fixed oil, extractive, red coloring matter, and a little volatile oil. A medicinal wine has been prepared from the fruit. (*Med. and Surg. Reporter*, Feb. 9, 1867.)

Medical Properties and Uses. Sumach berries are astringent and refrigerant. A strong decoction, or the fluid extract diluted, affords a very effective and pleasant gargle in *angina*, especially in combination with potassium chlorate.

RHUS TOXICODENDRON. U. S. Rhus Toxicodendron. [Poison Ivy.]

(RHŬS TŎX-Ĭ-CŌ-DĔN'DRON.)

"The fresh leaves of Rhus radicans,† Linné (nat. ord. Anacardieæ)." *U. S.*

Toxicodendron, *U. S.* 1870; Sumach vénéneux, *Fr.;* Gift-Sumach, *G.;* Albero del Veleno, *It.*

Rhus toxicodendron, Linn., or poison oak, is a shrub of the Southern States from one to three feet high, with leaflets angularly indented, and pubescent beneath. But this character of the foliage is probably not constant; and the stunted growth may be owing to peculiarities of situation. The Rhus Toxicodendron of the U. S. P. is the product of *Rhus radicans*, a woody vine, which is commonly known as *Poison*, *Climbing*, or *Three-leaved Ivy*. Dr. Bigelow

* Prof. Procter obtained from the berries *malic acid* by the following process. Pour boiling water on the ripe berries; macerate for twelve hours; strain, evaporate to one-fourth, and again strain; resume the evaporation, and continue it till the liquid assumes the consistence of thin syrup; then set it aside to crystallize. Wash the crystals of acid calcium malate with a little water, and recrystallize from a boiling solution. Dissolve the salt in hot water, and decompose it with a solution of lead acetate. Wash the precipitated lead malate, suspend it in water, and pass hydrogen sulphide through the liquid until the whole of the lead is separated. Lastly, filter, and evaporate to dryness in a porcelain vessel.

† There are four indigenous species of Rhus which are poisonous,—*R. toxicodendron*, *R. venenata*, *R. pumila*, and *R. diversiloba*.

R. vernix, L. (syn. *R. venenata*, D. C.). *Swamp sumach* is a beautiful shrub or small tree, usually ten or fifteen feet high, but sometimes thirty feet. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles beautifully red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuated, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers are dioecious. They are very small, greenish, and in loose axillary panicles. The berries are small, roundish, and greenish white. The tree grows in swamps and low grounds from Canada to Carolina, and flowers in June and July. It is thought to be identical with *R. vernicifera* of Japan. Dr. Bigelow found that the opaque whitish juice which exudes from our native plant when wounded, and which becomes permanently black on exposure, may be made to afford a brilliant, glossy, durable varnish by prolonged boiling. *R. venenata* is more poisonous than *R. toxicodendron*. Persons coming within its influence are more apt to be affected with the poison, and generally suffer more severely. The whole body is sometimes enormously swollen, and the patient for many days scarcely able to move; but the complaint almost always spontaneously subsides without destroying life. The susceptibility to the influence of the poison is exceedingly various, and some persons handle the plant with impunity.

Rhus pumila, Michaux, is a Southern species, growing in upper Carolina, and not more than a foot in height. It is characterized by its pubescent branches and petioles, by its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath, and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

Rhus diversiloba, Torrey & Gray (syn. *R. lobata*. Hooker, *Flor. Bor. Am.* i. 127, t. 46), has a somewhat climbing stem, with short, leafy branches. The leaves have three or rarely five leaflets, which are very obtuse, in the female plant slightly, in the male rather deeply pinnately lobed, the lobes being very obtuse, and the incisions acute. The flowers are in axillary, racemose panicles often shorter than the petioles; the fruit is white, somewhat pubescent, and subglobose. The leaves in the male and the female plant are so different that they might readily be mistaken for different species. (*Torrey & Gray.*) Though generally a shrub, the plant sometimes climbs over large trees, and has a stem six inches in diameter. The poisonous effects of this plant are described by Dr. C. A. Canfield (*A. J. P.*, 1860, p. 412), who found an invariable antidote to its effects in another California plant, *Grindelia hirsutula*, applied to the part either simply bruised or in the form of strong decoction.

Rhus vernicifera, which yields the Japanese lacquer, seems to have a similar action to the American poisonous Rhus. It contains a volatile acid, *urushic*, upon which its activity probably depends.

states that the young plants of *R. radicans* do not put forth rooting fibres until several years old, and are influenced in this respect by the contiguity of supporting objects.

The leaves are officially described as "long-petiolate, trifoliolate; the lateral leaflets sessile or nearly so, about 10 Cm. long, obliquely ovate, pointed; the terminal leaflets stalked, ovate or oval, pointed, with a wedge-shaped or rounded base; the leaflets entire and glabrous, or variously notched, coarsely toothed or lobed, more or less downy; when dry, papery and brittle; inodorous; taste somewhat astringent and acrid. The fresh leaves abound with an acrid juice, which darkens when exposed to the air, and, when applied to the skin, produces inflammation and swelling. The leaves should, therefore, not be touched with bare hands. Rhus Toxicodendron should not be confounded with the leaves of *Ptelea trifoliata* Linné (nat. ord. *Rutaceæ*), which are similar in appearance, but have all the leaflets sessile." *U. S.*

This species of Rhus grows in woods, fields, and along fences from Canada to Georgia. It flowers in June and July. When wounded it emits a milky juice, which becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it; applied to the skin it frequently causes inflammation and vesication; and its emanations produce in certain persons, when they come into the vicinity of the plant, an exceedingly troublesome erysipelatoid affection, particularly of the face. Itching, redness, a sense of burning, tumefaction, vesication, and ultimate desquamation, are some of the attendants of this poisonous action. The swelling of the face is sometimes so great as almost entirely to obliterate the features. The effects are experienced soon after exposure, and usually begin to decline within a week. A light, cooling regimen, with saline purgatives, and the local use of cold lead water, are the best remedies. Alkaline applications would seem to be indicated by the discovery of toxicodendric acid as a constituent of the plant, and the probable cause of the eruption. Dr. A. Livezey, of Lumberville, Pa., strongly recommends a saturated tincture of lobelia as a local application in this affection. He applies it by means of linen or muslin cloths, and believes that it arrests the inflammation. (*Boston Med. and Surg. Journ.*, lv. 262.) According to the late Prof. Procter, who was himself very susceptible to this poison, a weak alkaline solution, applied immediately after exposure, seldom fails to prevent the effects; and after the vesicles are formed, he found that Monsel's solution (*Liquor Ferri Subsulphatis*, U. S.), introduced by a pointed instrument into the vesicle, renders it abortive. (*A. J. P.*, Nov. 1863, p. 506.) Analyzed by Dr. Joseph Khittel, the leaves yielded tannic acid of the variety which gives greenish precipitates with salts of iron, chlorophyll, wax, fixed oil, resin, sugar, albumen, gum, pectin, starch, oxalic acid, a peculiar neutral substance, and a *volatile alkaloid*, on which the poisonous properties of the plant were supposed to depend. (*A. J. P.*, 1858, p. 544.) This supposed alkaloid probably does not exist. Prof. Maisch thought that the activity of the plant depended upon an acid (*toxicodendric acid*). To obtain this acid, the leaves were bruised with 6 per cent. of slaked lime, and after maceration with water were expressed. The expressed liquid, having been mixed with an excess of sulphuric acid, was distilled, and the vapors were condensed, partly by themselves, so as to obtain the pure acid, and partly in water containing barium carbonate in suspension, so as to get barium toxicodendrate. The solution thus obtained was colorless and strongly acid. (*A. J. P.*, Jan. 1866.) Dr. F. Pfaff has obtained Maisch's toxicodendric acid both in the form of barium salt and as free acid in aqueous solution, and found both to be non-toxic. The real active principle he found to be a non-volatile oil. This oil, which he terms *toxicodendrol*, is present in all parts of the plant, whether in a fresh green state or in old and dried specimens. *R. venenata* yields a larger percentage of the oil than *R. toxicodendron*, but no difference was found in the oils from the two. This oil applied to the skin causes the well-known eruption. Pfaff recommends a washing with alcoholic solution of lead acetate, as the oil is soluble in alcohol and forms a lead compound nearly insoluble. (*Proc. A. P. A.*, 1895, 843, and 1898, 865.)

Medical Properties and Uses. *Rhus toxicodendron* is a powerful local irritant, and seems also to be possessed of narcotic properties. In the cases of two children poisoned by eating each about half a pint of the fruit (*A. J. Med. Sci.*, April, 1866), a few hours after the ingestion, drowsiness and stupor came on, soon followed by vomiting, first of the partially digested fruit, and afterwards of a thick viscid fluid of a wine color. This was succeeded by convulsive movements of different parts of the body, with slight delirium. The pupils were dilated. The respiration was hurried, the pulse at first full and strong, but afterwards slow, small, frequent, and feeble. Recovery occurred after administration of sodium carbonate. In three cases poisoned by infusion of the root (*Med. and Surg. Rep.*, Nov. 1867), there

was a vesicular eruption over the body, more marked on the face; a dry, hoarse cough, burning along the throat and œsophagus to the stomach, high fever, scanty high-colored urine, nervous twitching, and occasionally wanderings of the mind. During convalescence there was wide-spread desquamation. As a local irritant, Rhus was at one time used in *nocturnal incontinence* and *cutaneous diseases*, but it has entirely passed out of vogue. Homœopathic practitioners have long used a strong tincture of Rhus in very small repeated doses in the treatment of *subacute* and *chronic rheumatism*, and the practice has recently found imitation. Some years ago Dr. H. C. Wood made extended trials of the remedy, using a homœopathic tincture obtained from a homœopathic pharmacy, in various doses (homœopathic, small, and large), upon a large number of cases of *subacute*, *chronic*, and *acute rheumatism*, in the Philadelphia Hospital, but he was not able to perceive that the patients progressed more rapidly when taking it than when they were simply nursed. The best preparation would undoubtedly be a concentrated alcoholic tincture, made from the green drug; the so-called mother-tincture is said to be of the strength of one to four. Dose, from one to five drops, three times a day. The solid extract is an ineligible preparation, owing to the extreme volatility of the active principle of the crude drug. For the violent dermatitis which is produced by the poison ivy very numerous specifics have been from time to time proposed. There seems, however, to be no method of treatment better than the use of lead water and laudanum. If the belief of Pfaff be correct, that the acrid substance is a fixed oil, thorough washing and irrigation of the part with a dilute solution of sodium carbonate would seem to be indicated for the removal of the irritant.

ROSA CENTIFOLIA. U. S. Pale Rose.

(RŌ'ṢẠ CĔN-TI-FŌ'LI-Ạ.)

"The petals of Rosa centifolia, Linné (nat. ord. Rosaceæ)." *U. S.*

Cabbage-rose Petals; Flores Rosæ, *P. G.;* Flores Rosarum Incarnatarum; Rose pâle, Roses à cent feuilles, *Fr.;* Hundertblätterige Rose, Rosenblätter, *G.;* Rosa pallida, *It.;* Rosa de Alexandria, *Sp.*

Rosa centifolia. L. *Sp. Pl.* (1753) 491; Willd. *Sp. Plant.* ii. 1071; *B. & T.* 105. This species of rose has prickly stems, usually from three to six feet high. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale red color, and supported upon peduncles beset with short bristly hairs. The germ is ovate, and the segments of the calyx semi-pinnate. The varieties of *R. centifolia* are very numerous, but may be indiscriminately employed. The plant is cultivated in gardens all over the world, but its original country is not certainly known. It has sometimes been mistaken for the damask rose, which is a distinct species. The petals are described as "roundish-obovate and retuse, or obcordate, pink, fragrant, sweetish, slightly bitter and faintly astringent." *U. S.* They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. They contain, according to Enz, malic and tartaric acids, tannin, fat, resin, sugar, and a coloring matter which seems to be identical with that of the red rose. Their odor is said to be increased by iodine. It depends on a volatile oil, which may be separated by distillation with water. (See *Oleum Rosæ.*) They should be collected when the flower is fully expanded but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved for a considerable time by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance. They are slightly laxative, and are sometimes administered in syrup combined with cathartic medicines; but their chief use is in the preparation of rose water. (See *Aqua Rosæ.*)

ROSA GALLICA. U. S. (Br.) Red Rose.*

(RŌ'ṢẠ GĂL'LI-CẠ.)

"The petals of Rosa Gallica, Linné (nat. ord. Rosaceæ), collected before expanding." *U. S.*
"The fresh and dried unexpanded petals of Rosa Gallica. From cultivated plants." *Br.*

Rosæ Gallicæ Petala, *Br.;* Red-rose Petals; Flores Rosarum Rubrarum; Rose de Provins, Roses rouges, *Fr.;* Französische Rose, Essigrosen, Essigrosenblätter, *G.;* Rosa domestica, *It.;* Rosa rubra 6 Castillara, *Sp.*

* Under the name of *Rosæ Caninæ Fructus* the Br. Ph. formerly recognized the fruit of the *Rosa Canina*, the acidulous pulp of which is still occasionally employed in Europe for the preparation of a confection. The *dog rose, wild brier*, or *hep-tree*, of Europe, is distinguished by its glabrous ovate ovaries, smooth peduncles, prickly stem and petioles, and ovate, smooth, rigid leaves. It is eight or ten feet high, and bears white or pale red flowers, having usually five obcordate fragrant petals. The plant has been introduced into this country, but is not much cultivated. The fruit is fleshy, smooth, oval, red, and of a pleasant, sweet, acidulous taste. It contains 30 per cent. of sugar, uncombined citric and malic acids, and salts of these acids.

Rosa gallica. L. *Sp. Pl.* (1753) 492; Willd. *Sp. Plant.* ii. 1071; *B. & T.* 104. This species is smaller than *R. centifolia*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson color, and less numerous than in the preceding species. In the centre is a crowd of yellow anthers on thread-like filaments, and as many villose styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United States.

The drug is officially described as "usually in small cones, consisting of numerous imbricated, roundish, retuse, deep purple-colored, yellow-clawed petals, having a roseate odor and a bitterish, slightly acidulous and distinctly astringent taste." *U. S.* The petals should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odor, which is less fragrant than that of *R. centifolia*, is improved by drying. They have a velvety appearance, a purplish-red color, and a pleasantly astringent and bitterish taste. Their constituents, according to M. Cartier, are tannin, gallic acid, coloring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassa, insoluble salts of lime, silica, and ferric oxide. (*Journ. de Pharm.*, vii. 531.) According to M. Filhol, the astringency of red roses is ascribable less to tannic acid, of which they contain but a trace, than to *quercitrin*, which he obtained in notable proportion, and with which their color is probably connected. Rochleder found that in red roses the gallic acid is accompanied by quercitannic acid. They also contain much uncrystallizable sugar. (*Répert. de Pharm.*, Mai, 1863.) The sensible properties and medical virtues of the flowers are extracted by boiling water. Their coloring matter, according to Senier (*Year-Book of Pharm.*, 1877, p. 63), is an acid, which appears to form crystallizable salts with potassium and sodium, and amorphous ones with the heavy metals. Senier gives as the formula of the insoluble lead compound $Pb_2C_{21}H_{29}O_{30}$. Their infusion is of a pale reddish color, becoming bright red on the addition of sulphuric acid. As their color is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Medical Properties and Uses. Red roses are slightly astringent and tonic, and were formerly thought to possess peculiar virtues. They are at present chiefly employed as affording an elegant vehicle for tonic and astringent medicines.

RUBUS. U. S. Blackberry.

(RŪ'BŬS.)

"The bark of the root of Rubus villosus, Aiton, Rubus Canadensis, Linné, and Rubus trivialis, Michaux (nat. ord. Rosaceæ)." *U. S.*

Ecorce de Ronce noir, *Fr.;* Brombeerrinde, *G.*

Of this extensive genus not less than twenty species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, etc. Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. They are naturally divided into the *raspberries*, in which the edible fruit is composed of pulpy, one-seeded, coherent little drupes, separate from the dry receptacle, and the *blackberries*, in which the receptacle is juicy and coheres with the drupes to form the fruit.

1. *Rubus canadensis.* L. *Sp. Pl.* (1753) 494; Willd. *Sp. Plant.* ii. 105; Gray, *Manual of Bot.*, etc., 121.—*R. trivialis.* Pursh, *Flor. Am. Sept.* 347. The *dewberry*, sometimes also called *low running blackberry*, or *creeping blackberry*, has a slender, somewhat prickly stem, which runs along the ground and occasionally puts forth roots. The leaves are composed of three or five leaflets, which are ovate or ovate-lanceolate, generally pointed, sharply serrate, thin, and nearly smooth. The flowers are large, white, and arranged in racemes, with leaf-like bracts. The plant grows abundantly in old fields and neglected grounds from Newfoundland south to Louisiana and west to the Indian Territory. Its fruit, which ripens somewhat earlier than does that of *R. villosus*, is large, black, and of a very pleasant flavor.

2. *R. villosus.* Ait. *Hort. Kew.* (1789) 210; Willd. *Sp. Plant.* ii. 1085. The stem of the *blackberry* is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalk and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. This plant is very common in thickets, half-cultivated fields, etc., extending from New England to Florida and west to Arkansas, fruiting in August and September. It is the original of the cultivated blackberry.

R. trivialis, Michaux, is distinguished by its shrubby, procumbent, bristly habit, and its leathery, nearly smooth, evergreen leaves. The flowers are large and borne on from one- to three-flowered peduncles. The plant grows in the Southern United States, affecting especially sandy soils. It flowers earlier than the two species mentioned above.

The blackberry root is branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light brownish or reddish-brown color, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark ash color, without any reddish tinge. Both are inodorous. The bark is "in thin, tough, flexible bands, outer surface blackish or blackish-gray, inner surface pale brownish, sometimes with strips of whitish, tasteless wood adhering; inodorous; taste strongly astringent, somewhat bitter." *U. S.* Its virtues are extracted by boiling water and by diluted alcohol, and depend chiefly upon tannin, which is an abundant constituent.* The woody part of the roots is inert.

Medical Properties and Uses. Dewberry and blackberry roots are tonic and strongly astringent. They have long been a favorite domestic remedy in bowel affections, and from popular favor have passed into regular medical use. Given in decoction, they are usually acceptable to the stomach, without being offensive to the taste, and may be employed with great advantage in cases of *diarrhœa* from relaxation of the bowels, whether in children or in adults. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint, of which from one to two fluidounces (30–60 C.c.) may be given to an adult three or four times, or more frequently, during the twenty-four hours. The dose of the powdered root is from twenty to thirty grains (1·3–1·95 Gm.). The fluid extract is an excellent preparation: dose, thirty minims (1·9 C.c.).

RUBUS IDÆUS. U. S. Raspberry.

(RÛ'BŬS I-DÆ'ŬS—ī-dē'ŭs.)

"The fruit of Rubus idæus, Linné (nat. ord. Rosaceæ)." *U. S.*

Both the plant and the fruit of the ordinary cultivated raspberry are too well known to need description. For the cultivated fruit that of the ordinary *wild red raspberry*, of the extreme Northern United States, *R. strigosus* (Michaux), may very well be substituted, as in flavor it is at least equal to the cultivated berry. The specific distinctness of the two plants is questionable. The U. S. P. also allows the substitution of the fruit of *R. occidentalis*, Linné, or the *wild black raspberry*, of the Middle United States; but this is greatly inferior.

RUMEX. U. S. Rumex. [Yellow Dock.]

(RÛ'MĔX.)

"The root of Rumex crispus, Linné, and of some other species of Rumex (nat. ord. Polygonaceæ)." *U. S.*

Yellow Dock; Radix Rumicis, s. Lapathi; Racine de Patience frisée, *Fr.*; Grindwurzel, *G.*

Several species of Rumex have sour leaves, and are distinguished by the common name of *sorrel* from the others, which are called *dock*. Of the former, *Rumex acetosa*, or *common English sorrel*, formerly held a place in the London and Dublin Pharmacopœias. *R. acetosella* is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to acid potassium oxalate with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in scurvy. For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. (See *Wood's Quarterly Retrospect*, i. 109.) *R. scutatus*, L., of Europe, Northern Africa, Asia Minor, and the Caucasus, also ranks among the sorrels.

Of the proper docks, the roots of *R. patientia* and *R. alpinus*, European plants, and of *R. aquaticus*, *R. acutus*, and *R. sanguineus*, belonging both to Europe and to the United States,

* *Aromatic Syrup of Blackberry.* Take of Blackberry Root ℥ij; Cinnamon, Cloves, each, ʒiss; Mace ʒi; Sugar ℥xxx. Reduce the root and spices to a powder which will pass through a sieve of 50 meshes to the square inch, moisten this with two fluidounces of alcohol, put into a percolator and displace with water till 17 fluidounces have passed, and dissolve the sugar in the filtrate. A fluidounce is equivalent to 30 grains of the root. (*A. J. P.*, Nov. 1859, p. 552.)

may be employed indiscriminately with those of the official species. *R. britannica* and *R. obtusifolius* were formerly official. *R. hydrolapathum* (Hudson), which is the *R. aquaticus* of the old Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the skin. The docks are herbaceous plants with perennial roots. The flowers are in terminal or axillary panicles. Some of the species are dicœcious; but the one here described has perfect flowers.

Rumex crispus. L. *Sp. Pl.* (1753) 335; Willd. *Sp. Plant.* ii. 251; Gray, *Manual of Botany*, etc., 377. From a perennial, spindle-shaped, yellow root, which penetrates deeply into the ground, a stem rises annually, three or four feet high, furnished with smooth, lanceolate leaves, strongly waved at their margins, and terminating in panicled racemes of small, inconspicuous, greenish flowers. The upper leaves are truncate or cordate at the base, and those which spring from the root have long footstalks. The flowers are in crowded whorls, upon long wand-like racemes, which are leafless above. The valves or inner sepals of the calyx are roundish cordate, entire or slightly denticulate, and one or all grain-bearing. A native of Europe, but naturalized in this country, and now a common weed growing in roads and fields.

Dock root, from whatever species derived, has an astringent, bitter taste, with little or no smell. It readily yields its virtues to water by decoction. It is officially described as "from 20 to 30 Cm. long, about 10 to 15 Mm. thick, somewhat fusiform, fleshy, nearly simple, annulate above, deeply wrinkled below; externally rusty brown, internally whitish, with fine, straight, interrupted, reddish, medullary rays, and a rather thick bark; fracture short; odor slight, peculiar; taste bitter and astringent." *U. S.* According to Riegel, the root of *R. obtusifolius* contains resin, extractive matter resembling tannin, starch, mucilage, albumen, lignin, sulphur, and various salts, among which are calcium phosphate and different acetates and malates. (*Journ. de Pharm.*, 3e sér., i. 410.) The leaves of most of the species are edible when young, and are occasionally used as spinach. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow color. According to Dr. J. H. Salisbury (*N. Y. Journ. Med.*, March, 1855), the petioles of the leaves contain nearly one per cent. of oxalic acid; the cortical part of the root, which is the most active, yielded, on analysis, starch, a little sugar, albuminous matter, gummy matter, bitter extractive, tannic acid of the kind which gives green precipitates with the salts of iron, lignin, and various salts. The root yields its virtues to water and to alcohol, but is injured by long boiling.*

Medical Properties and Uses. Dock root is astringent and gently tonic, and is also supposed to possess an alterative property, which renders it useful in *scorbutic disorders* and in *cutaneous eruptions*, particularly the *itch*, in the cure of which it enjoyed at one time considerable reputation. It is said to have proved useful in *scrofula* and *syphilis*. Dr. Thomson found a decoction of the root of *R. patientia* very efficacious in obstinate ichthyosis. *R. aquaticus* and *R. britannica* are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of *R. crispus* and *R. obtusifolius;* and *R. alpinus* has in some parts of Europe the name of *mountain rhubarb*. This resemblance is not singular, as the two genera belong to the same natural family. Dock root is given in powder or in decoction. Two ounces (62·2 Gm.) of the fresh root bruised, or one ounce (31·1 Gm.) of the dried, may be boiled in a pint (472 C.c.) of water, of which two fluidounces (60 C.c.) may be given at a dose, and repeated as the stomach will bear it. The root has often been applied externally, in the shape of ointment, cataplasm, and decoction, to the *cutaneous eruptions* and *ulcerations* for which it has been used internally. The powdered root is recommended as a dentifrice, especially when the gums are spongy. Geo. G. Flemyng (*London Lancet*, i. 1896) reported the death of two sisters, aged respectively five and six and a half years, preceded by symptoms of oxalic acid poisoning as the result of the ingestion of sorrel leaves.

SABINA. U. S. Savine.

(SĄ-BĪ′NĄ.)

"The tops of Juniperus Sabina, Linné (nat. ord. Coniferæ)." *U. S.*

Savine Tops; Summitates (Herba) Sabinæ, *P. G.;* Sabine, *Fr.;* Sevenbaum, Sadebaumspitzen Sevenkraut, *G.;* Sabina, *It., Sp.*

JUNIPERUS. See *Juniperus.*

Juniperus sabina. L. *Sp. Pl.* (1753) 1039; Willd. *Sp. Plant.* iv. 852; *B. & T.* 254. This is

* From the root of *Rumex nepalensis*, Wall., which is largely used in Madras as an astringent for medicinal purposes and for dyeing, Dr. O. Hesse has separated three crystalline substances to which he gives the names of *rumicin*, *nepalin*, and *nepodin*. (*P. J. Tr.*, lvi.; also *Proc. A. P. A.*, 1896, 551.)

an evergreen shrub, from three to fifteen feet high, with numerous erect, pliant branches, much subdivided. The bark of the young branches is light green, that of the trunk rough and reddish brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, dark green, glandular in the middle, opposite, and imbricated in four rows. The flowers are male and female on different trees. The fruit is a blackish purple berry of an ovoid shape, marked with tubercles and the remains of the calyx and petals, and containing three seeds. The savine is a native of the south of Europe and the Levant, and is said to grow wild in the neighborhood of our northwestern lakes. The ends of the branches, and the leaves by which they are invested, are collected for medical use in the spring. When dried they are very much faded in color. They are officially described as "short, thin, subquadrangular branchlets; leaves rather dark green, in four rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, on the back with a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste nauseous, resinous, and bitter." *U. S.* They have a strong, heavy, disagreeable odor, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil. (See *Oleum Sabinæ*.) The leaves impart their virtues to alcohol and to water. Mr. C. H. Needles found in them volatile oil, gum, tannic or gallic acid, resin, chlorophyll, fixed oil, bitter extractive, lime, and salts of potassa. (*A. J. P.*, xiii. 15.)

The tops of *Juniperus virginiana*, or common red cedar, are sometimes substituted in the shops for savine, to which they bear so close a resemblance as to be with difficulty distinguished. The two species, however, differ in their taste and smell. In *J. virginiana*, moreover, the leaves are sometimes ternate.

Medical Properties and Uses. Savine is highly irritant, and is supposed to have a special direction to the uterus. It has been much used in *amenorrhœa* and *atonic menorrhagia*, and occasionally as a remedy for *worms*. The late Professor Chapman strongly recommended it in *chronic rheumatism;* and it is employed in Germany, both internally and externally, in *chronic gout*. In overdoses it may produce dangerous gastro-intestinal inflammation, and it should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution. The dose of the fluid extract is from fifteen to twenty drops (0·75–1 C.c.); of the oil, five drops (0·24 C.c.). As an external irritant, savine is useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as in this country savine ointment is often feeble, either from the age of the drug or from the substitution of red cedar, it has fallen into disrepute. In powder or infusion, savine is used in Europe as an application to *warts*, *indolent* or *gangrenous ulcers*, *psora*, and *tinea capitis;* and the expressed juice of the fresh leaves, diluted with water, is sometimes used for similar purposes.

SACCHARUM. U. S. (Br.) Sugar. [Cane Sugar.]

$C_{12}H_{22}O_{11}$; 341·2. (SĂC'ȻHẠ-RŬM.) $C_{12}H_{22}O_{11}$; 342.

"The refined sugar obtained from Saccharum officinarum, Linné, and from various species or varieties of Sorghum (nat. ord. Gramineæ); also from one or more varieties of Beta vulgaris, Linné (nat. ord. Chenopodiaceæ)." *U. S.* "A crystallized sugar, $C_{12}H_{22}O_{11}$, obtained from the juice of the sugar-cane." *Br.*

Saccharum Purificatum, *Br.;* Sucrose; Sucre, Sucre pur, Sucre de Canne, Sucre en Pains, *Fr.;* Weisser Zucker, Zucker, Rohrzucker, *G.;* Zucchero Pane, *It.;* Azucar de Pilon, Azucar refinado, *Sp.*

Saccharum officinarum. L. *Sp. Pl.* (1753) 54; Willd. *Sp. Plant.* i. 321; *Philos. Trans.* lxix. 207. The *sugar cane* is an herbaceous plant, possessing a jointed, succulent root, from which arise several shining, jointed, solid stems, from an inch to two inches in diameter, from six to twelve feet high, and containing a white and juicy pith. The color of the stem is yellow, greenish yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green color inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to the Indian corn. Four varieties are mentioned: 1, the *common*, with a yellow stem; 2, the *purple*, with a purple stem and richer juice; 3, the *gigantic*, with a very large light-colored stem; and, 4, the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and the greater length of the hairs which surround the flowers.

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be removed. At the end of a year the plant generally flowers, and in four or five months afterwards the canes are completely ripe, at which time they have a yellowish color and contain a sweet viscid juice. The quantity of sugar which they yield is variable. According to Avequin, of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent., of uncrystallizable sugar from 3½ to 4 per cent. Cane juice is said to contain 17 per cent. of crystallizable sugar, though not more than 11 per cent. is extracted in practice.

Among the saccharine principles distinguished by the chemist are cane sugar, or sugar properly so called, derived from the sugar cane, the beet, and the sugar maple, and having the formula $C_{12}H_{22}O_{11}$; lactose or milk sugar, and maltose, a product of the action of malt upon cereals, possessing the same formula; glucose, including dextrose or grape sugar, levulose or fruit sugar, the mixture of the two produced by the alteration of cane sugar and known as invert sugar, and that resulting from the change of starch and starch-containing cereals; arabinose, from gum arabic, agreeing with glucose in the formula $C_6H_{12}O_6$; mannite (mannitol), and dulcite (dulcitol), which are alcohol-like compounds closely related to the true sugars. Quercite, pinite, and inosite were formerly regarded as either pentatomic alcohols or glucoses, but are now considered to be hexahydro derivatives of a pentatomic phenol as yet unprepared. *Glucose*, or *grape sugar*, is conveniently obtained by spreading crystalline honey on porous tiles, dissolving what remains on their surface in alcohol, and crystallizing. The product is about one-fourth of the weight of the honey. It is also prepared from starch by the action of very weak sulphuric acid; and this industry has assumed enormous proportions in this country in the last few years. In the report of the 1890 census, the capacity of the factories in the United States was estimated at 43,000 bushels of corn per day. The term glucose is applied to the syrupy product of this process, while the name grape sugar is limited to the solid substance from the same source. The process, in outline, is as follows. The corn is first soaked for two or three days in warm water, and is then ground on specially-prepared stones with a stream of water. The meal is next passed into a trough, the bottom of which is made of fine bolting-cloth. Here the starch is washed through and led to large tanks, where it is allowed to settle. It is next beaten up with caustic soda, to separate the gluten, and the starch is again allowed to settle in long shallow troughs. The starch, washed from all adhering alkali, is next beaten up with water into a cream, and conducted into the converting tubs. These tubs are supplied with coils of copper steam piping, and are made of wood. Here the starch cream is treated with diluted sulphuric acid, and steam is allowed to bubble up through the mixture from small holes in the copper pipes. This process of conversion, which is called "open conversion," is completed in about two hours. Another method is called "close conversion." The substances are enclosed in stout copper cylinders and subjected to the action of superheated steam. This process occupies about fifteen minutes. After conversion, the acid is neutralized by marble dust and animal charcoal. Since the calcium sulphate which is formed in this operation is slightly soluble, barium carbonate has been used instead of marble dust; but its use has not become general. After neutralization, the liquid is filtered through cloth and animal charcoal, and is then conveyed to the vacuum-pan. When glucose syrup alone is desired, the process of conversion is stopped when the starch has disappeared, so that the syrup contains both glucose and dextrin, while when solid grape sugar is desired, the conversion is carried further to the change of dextrin into dextrose. Glucose can be obtained as a hydrate in small and laminated crystals from aqueous solution, and anhydrous in hard crystalline masses either from alcoholic solution or, by the process used by Dr. Arno Behr (*A. J. P.*, Aug. 1882, p. 397), from very concentrated aqueous solution. It is less sweet than cane sugar. It is also less soluble in water, and much more soluble in alcohol. It has the sp. gr. 1·54–1·57 when anhydrous. Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalies, with which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, grape sugar undergoes very little alteration. Its solution rotates the plane of polarization of polarized light to the right, and is capable of undergoing the vinous fermentation directly, without passing through any intermediate state. It is characterized, also, in boiling solution, by reducing alkaline copper tartrate, and by becoming brown by the action of the alkalies. The name of *glucosides* has been given to certain organic substances which are resolvable, by the presence of acids, or other slight chemical influence, into glucose and some other proximate principle, as in the instance of one variety of tannic acid, which is resolved into glucose and gallic acid. E. Fischer

announced (*Berichte der Chemisch. Ges.*, 1893, 2400) the discovery of a general method for the formation of glucosides. He finds that, if a glucose be dissolved in an alcohol and gaseous hydrochloric acid be passed into the solution to saturation, the two compounds unite with the elimination of water to form a glucoside or ester of the two. He has found this reaction to extend to methyl, ethyl, propyl, isopropyl, amyl, allyl, and benzyl alcohols, to ethylene, glycol, and glycerin, and even to the oxyacids or alcohol acids like lactic acid. He has tested it for mannose, galactose, dextrose, fructose, gluco-heptose, arabinose, xylose, and rhamnose. *Fruit sugar*, or *levulose*, is an isomeric form of glucose, found in honey and in the juice of fruits; an uncrystallizable mixture of dextrose and levulose (both varieties of glucose) is generated from cane sugar by solution in water or weak acids, and long boiling. Hence it is present in molasses. An aqueous solution of this sugar, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. In consequence of its effect on polarized light, it has been named by the French chemists *invert sugar* (*sucre interverti*), its rotatory power being the reverse of that of the sugar from which it is produced. A solution of *cane sugar*, like that of grape sugar, has a rotating power to the right. When it ferments, it is first changed into uncrystallizable sugar, according to the reaction $C_{12}H_{22}O_{11}+H_2O=(C_6H_{12}O_6)_2$; and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the uncrystallizable sugar formed.

Classification of the Carbohydrates. The group of the carbohydrates has been studied during the last few years with the most brilliant results by Emil Fischer, who has not only made numerous syntheses in this group, but has greatly widened our knowledge of the relations of the several sugars, making necessary a more comprehensive classification. Thus, while no sugars are found in nature containing less than six atoms of carbon, synthetic compounds are formed belonging in the first or monosaccharide class which contain three, four, and five atoms of carbon, as well as others containing seven, eight, and nine atoms of carbon. The classification given below, enlarged in accordance with recent discoveries, is based on that of Tollens, which was given in the 16th edition of the U. S. D.

I. Monosaccharides.

Trioses. Glycerose, $C_3H_6O_3$ (prepared from glycerin by oxidation).

Tetroses. Erythrose, $C_4H_8O_4$ (prepared from erythrite by oxidation).

Pentoses. Arabinose, $C_5H_{10}O_5$ (prepared by the action of dilute sulphuric acid upon lævorotatory gum arabic); xylose, $C_5H_{10}O_5$ (prepared by boiling beech wood and jute with dilute acids); rhamnose or isodulcite, $C_5H_9(CH_3)O_5$, methyl pentose (obtained in the decomposition of glucosides like quercitrin).

Hexoses. Glucose or dextrose, $C_6H_{12}O_6$; fructose or levulose, $C_6H_{12}O_6$; mannose, $C_6H_{12}O_6$ (obtained by the careful oxidation of mannite); galactose, $C_6H_{12}O_6$.

Heptoses. $C_7H_{14}O_7$. Manno-heptose (obtained artificially from the corresponding mannose); gluco-heptose (obtained artificially from the corresponding glucose).

Octoses. $C_8H_{16}O_8$. Manno-octose (prepared from the corresponding mannose); gluco-octose (prepared from the corresponding glucose).

Nonoses. $C_9H_{18}O_9$. Manno-nonose (prepared from the corresponding mannose); gluco-nonose (prepared from the corresponding glucose).

II. Disaccharides and Trisaccharides.

Tribioses and *tetrabioses* are as yet unknown.

Pentabioses. Arabinon, $C_{10}H_{18}O_9$ (has been prepared by the moderated action of dilute sulphuric acid upon arabic acid).

Hexabioses. Cane sugar, $C_{12}H_{22}O_{11}$; milk sugar, $C_{12}H_{22}O_{11}$; maltose, $C_{12}H_{22}O_{11}$; isomaltose, $C_{12}H_{22}O_{11}$; trehalose, $C_{12}H_{22}O_{11}$.

Hexatrioses. Meletriose or raffinose, $C_{18}H_{32}O_{16}$; melezitose, $C_{18}H_{32}O_{16}$.

III. Polysaccharides.

(*a*) *Crystallizable polysaccharides.* Gentianose, lactosin.

(*b*) *Uncrystallizable polysaccharides.* Starches, lichenin, inulin, glycogen, dextrin, natural gums, pectin substances, cellulose, lignin, tunicin.

Cane sugar is manufactured extensively on the continent of Europe from the beet, and this industry is now growing in this country, especially in California. It is also largely produced in Canada and the northern parts of the United States from the sap of the sugar maple (*Acer saccharinum*). Cane sugar may also be obtained from cornstalks, and from the *Chinese sugar cane*, or *Sorghum saccharatum*, which latter source for a time assumed some importance in Kansas and the Northwest. In India, sugar is made from the sap of different species of palm. Crude *palm sugar* is called *jaggery*. Next in rank to the sugar beet as a source of cane sugar is the sugar cane, which is extensively cultivated in Africa, the East and West Indies (especially Cuba), Brazil, and some of our Southern States, particularly Louisiana.

Preparation and Purification. The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between a series of horizontally placed iron rollers in a mill, or they are cut in thin transverse slices and the juice extracted by diffusion with warm water. The juice, constituting 90 per cent. of the cane, though much less is actually obtained, is of a pale greenish color, sweet taste, and balsamic odor, and has a sp. gr. varying from 1·033 to 1·106. As it runs out it is received in suitable vessels, and, being quickly removed, is *immediately* mixed with lime, in the form of milk of lime, in the proportion of about 1 part of the earth to 800 parts of the juice, and heated in a boiler to 140° F. The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at leaving the juice still slightly acid. The gluten and albumen rise to the top, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by heat, the scum being carefully skimmed off as it forms. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, when it assumes a granular aspect, it is drawn off into wooden vessels with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish color, and moist. The syrup, by a new evaporation, furnishes an additional portion of sugar; and the liquid which finally remains, incapable of yielding more sugar with advantage, is called *molasses*. Sugar produced in this way is called "open pan" sugar. It is now almost completely displaced by "vacuum-pan" sugar.

In the production of raw sugars by the vacuum-pan process, the juice, after "defecation" with lime and removal of excess of lime by carbonic acid gas, is run through large filters of bone-black, and then into the vacuum-pan for concentration. The vacuum-pan is a large evaporating pan, closed above by a dome-like top, which connects with an exhausting steam-pump, so that the liquid can be concentrated under very reduced pressure. The heat is supplied by coils of steam-pipes which run through the interior of the pan. The saccharine juice is evaporated in this until it begins to crystallize, and even after this fresh portions are added, so that the crystals already formed grow by accretion of fresh material. After the crystallization is complete, the warm mixture of crystals and syrup is run into "centrifugals," to which a rapid motion of revolution is given, and the crystals so drained and dried.

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture. M. Melsens, of Brussels, proposed a process, which consists in the use of calcium bisulphite. This salt is alleged to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 100° C. (212° F.) all coagulable matters; as a bleacher of pre-existing coloring matters, and a preventive of the formation of new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. This process is now largely used, and calcium bisulphite is used in British Guiana and other sugar-producing countries in immense quantities. M. Emil Pfeiffer proposed another refining process, which consists in the use of acid calcium phosphate, an agent previously recommended by Brande. M. Reynoso considered alumina the best defecating agent, having succeeded by means of it in throwing down almost all impurities most hurtful. He adds the acid aluminum phosphate to the cane juice, and decomposes this with lime, by which the calcium phosphate is produced and alumina separated; and all these, with some lime in excess, cause the elimination of coloring and nitrogenous matters, so that there remain in the liquid only some of the salts which normally accompany the sugar in the juice. (*Journ. de Pharm.*, 4e sér., ii. 232.)

The refining of brown sugar forms a distinct branch of business, and the methods pursued

have undergone many improvements. The sugar is first "melted"—that is, dissolved in hot water—and then clarified by heating it with bullock's blood. The clarified syrup is then strained through cloth filters, whereby it is rendered limpid. The clear straw-colored syrup from the bag filters is now run into the char filters,—that is, large filters filled with freshly ignited bone-black. The syrup after this filtration goes to the vacuum-pans. This great step in advance was taken by Messrs. Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam made to pass through a series of tubes traversing the boiler; and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction-pump, set in motion by a steam-engine, while it was heated by steam circulating round the boiler. In this way the syrup was made to boil at a lower temperature, and with a diminished contact of the air, and the loss of cane sugar by change into that which was uncrystallizable was in great measure avoided. Two, three, or even four vacuum-pans may be coupled together, so as to economize fuel, and the vapors arising from one made to heat the next, in which a more perfect vacuum exists, allowing of evaporation at still lower temperatures. Such a combination is called a double, triple, or quadruple effect apparatus.

After the syrup is sufficiently concentrated by any one of these methods, it is transferred to coolers, where it is agitated to cause it to granulate. In this state it is poured into unglazed earthen-ware moulds of a conical shape, with a hole in the apex, which is stopped with a paper plug. The moulds are placed, with the apex downwards, above stone-ware pots, intended to receive the uncrystallizable syrup. When the mass has completely concreted, the moulds are unstopped, to allow the colored syrup to drain off. To separate the remains of this syrup, the operation called *claying* is performed. This consists in removing from the base of the loaf a layer of sugar about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe-clay and water of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the colored syrup. Sometimes the purification is performed without the use of clay, by allowing a saturated solution of pure sugar to percolate the loaf. When all the colored syrup is removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*. The syrup which drains from the loaves contains a considerable quantity of cane sugar, and is used in subsequent operations. This process of forming *loaf-sugar* by claying and displacing colored syrup by white syrup is now almost entirely replaced by the process already described under raw sugars of crystallizing in the vacuum-pan and draining with a centrifugal. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar-house molasses*. Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar. The application of animal charcoal to the refining of sugar is now very extensive.

Commercial History. *Cane sugar* was known to the ancients. It was originally obtained from India, where it was extracted from the sugar cane. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce and costly as to be used exclusively as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently the cultivation of the cane extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the New World, to America, where it was pursued with the greatest success, and continues to be so. In America it was produced most abundantly in the West Indies, which supplied also a part of the consumption of Europe. The Cuban production, which at one time amounted to over 750,000 tons, has lessened greatly in recent years because of the disturbed condition of the island. The production in Louisiana, once large, diminished under the competition of the foreign beet sugar production, but in recent years, under the stimulus of a bounty, it has increased, and now amounts to about 300,000 tons per year. However, the American production from the sugar beet has developed rapidly in the last few years, advancing from 10,000 tons in 1892 to over 20,000 tons in 1893 and nearly 75,000 tons in 1898. This production centres in California, Nebraska, and Utah, but individual factories have been erected in New Mexico, Arizona, Michigan, and as far east as New York State.

The following figures show the production of sugar throughout the world from the two main sources, the sugar cane and the sugar beet. For 1893–94, beet-root sugar, 3,889,535 tons, cane sugar, 3,552,374 tons; for 1894–95, beet-root sugar, 4,792,530 tons, cane sugar, 3,570,413

tons; for 1895–96, beet-root sugar, 4,393,537 tons, cane sugar, 2,945,811 tons; for 1896–97, beet-root sugar, 4,960,000 tons, cane sugar, 2,747,500 tons.

The importations of raw sugars into the United States for 1896 were: raw sugar from the cane, 3,291,651,572 lbs., and raw sugar from the beet, 604,686,985 lbs.; for 1897, raw sugar from the cane, 3,053,328,238 lbs., and raw sugar from the beet, 1,865,577,495 lbs.

Properties. Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1·6. It forms "white, dry, hard, distinctly crystalline granules, odorless, and having a purely sweet taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 0·5 part of water, and in 175 parts of alcohol; in 0·2 part of boiling water, and in 28 parts of boiling alcohol; also soluble in 80 parts of boiling, absolute alcohol, but insoluble in ether, chloroform, or carbon disulphide. The aqueous solution, saturated at 15° C. (59° F.), has the specific gravity 1·345, and is miscible with water in all proportions. The aqueous or alcoholic solution of Sugar is neutral to litmus paper." *U. S.* "Colorless and inodorous separate crystals. Readily and completely soluble in half its weight of *water*, forming a clear bright syrup. When the syrup is heated to about 180° F. (82·2° C.) with *solution of potassio-cupric tartrate* or with *solution of copper sulphate* and excess of *solution of potassium hydroxide*, there should not result more than a trace of a red or yellowish precipitate (absence of glucose). Refined sugar should yield no reaction with the tests for calcium, chlorides, and sulphates." *Br.* Its solution, when thick and ropy, is called *syrup*, and when alcohol is mixed with it, the sugar is gradually deposited in crystals. An aqueous solution of sugar, kept in a warm place, has the property of corroding iron, partially immersed in it, just above the line where the surface of the liquid touches the metal; and the solution itself becomes impregnated with ferrous oxide, and of a deep red-brown color. A similar effect is produced on lead; but zinc and copper are but slightly acted on. (Dr. J. H. Gladstone, *Annals of Pharmacy*, iii. 208.) A solution of sugar possesses the property also of dissolving a large quantity of calcium hydrate, forming a compound called *calcium saccharate*. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *rock-candy*. When heated to 185° C. (365° F.), it melts into a viscid, colorless liquid, which on being suddenly cooled forms a transparent amorphous mass, called *barley sugar*. At a higher temperature (between 204·4° and 215·5° C. (400° and 420° F.) it loses two mols. of water, and is converted into a black porous mass, having a high lustre, called *caramel*.* At a still higher heat it yields combustible gases, carbonic acid, empyreumatic oil, and acetic acid, and there remains one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, and forms with the latter an imperfect combination: such mixtures are called *oleo-saccharures*. When in solution, it is not precipitated by lead subacetate, a negative property which distinguishes it from most other organic principles.

Tests. "Both the aqueous and the alcoholic solution of Sugar should be clear and transparent. When kept in large, well closed and completely filled bottles, the solutions should not deposit a sediment on prolonged standing (absence of *insoluble salts, ultramarine, Prussian blue*, etc.). If 1 Gm. of Sugar be dissolved in 10 C.c. of boiling water, the solution mixed with 4 or 5 drops of silver nitrate test-solution, then about 2 C.c. of ammonia water added, and the liquid quickly brought to the boiling point, not more than a slight coloration, but no black precipitate, should appear in the liquid after standing at rest for five minutes (absence of *grape-sugar*, or of more than a slight amount of *inverted sugar*)." *U. S.* Cane sugar may be distinguished from grape sugar by Trommer's test, which consists in the use of copper sulphate and caustic potassa. If a solution of cane sugar be mixed with a solution of copper sulphate, and potassa be added in excess, a deep blue liquid is obtained, which on being heated lets fall, after a time, a little red powder. A solution of grape sugar, similarly treated, yields, by heat, a copious greenish precipitate which rapidly changes to scarlet and eventually to dark red. Prof. Böttger finds that, when a liquid containing grape sugar is boiled with sodium carbonate and some basic bismuth nitrate, a gray coloration or blackening of reduced bismuth is produced. Cane sugar, similarly treated, has no effect on the test. Dr. Donaldson's test for sugar in the *animal fluids* is formed of 5 parts of sodium carbonate, 5 of caustic potassa, 6 of

* A coloring substance called *caramel brown* or *sucré couleur* is now largely manufactured from sugar by decomposing it by means of heat carefully applied. It is in the form either of a stiff paste, in which it is used for coloring leather, or of a syrup, for coloring liquids. Sucré couleur is now extensively manufactured abroad for coloring rum and spirituous liquors, beer, and wine. It is made exclusively from starch sugar, either by a simple process of heating, or by heating with addition of sodium carbonate or ammonium carbonate. (For details, see *Starch, Glucose, Starch Sugar, etc.*, by Wagner, translated by Frankel, 8vo, pp. 344, H. C. Baird & Co., Phila.)

potassium bitartrate, 4 of copper sulphate, and 32 of distilled water. A few drops of this solution being added to an animal fluid, and the mixture heated over a spirit-lamp, a yellowish-green color is developed, if sugar be present. J. Horsley's test for sugar in diabetic urine is an alkaline solution of potassium chromate, a few drops of which, boiled with the urine, will make it assume a deep sap-green color. M. J. Nicklés points out, in carbon tetrachloride, obtained by decomposing carbon disulphide by chlorine and aqueous vapor, a new test for distinguishing glucose and cane sugar. This test mixed with cane sugar in a glass tube, kept for some time near 100° C. (212° F.), causes a darkening of the sugar, gradually increasing till it becomes black. Glucose undergoes no such change. (*Journ. de Pharm.*, 4e sér., iii. 119.)

Action of Acids and Alkalies, etc. The mineral acids act differently on cane sugar according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid.*) The same acid, when weak, converts it into *saccharic acid*, confounded by Scheele with malic acid. Concentrated sulphuric acid chars it. Diluted hydrochloric acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable sugar, afterwards into grape sugar, and finally into *ulmin* and *ulmic acid.* Vegetable acids are supposed to act in a similar way. Maumené has found that cane sugar undergoes the change into uncrystallizable sugar when kept for a long time in aqueous solution, as well as when heated with acids. When the boiling with acids is prolonged for several days in open vessels, oxygen is absorbed, and, besides ulmin and ulmic acid, formic acid is generated. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid, as, according to his observation, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone. Not only does cane sugar change into the uncrystallizable variety when boiled with water, but, as clearly shown by an experiment of M. E. M. Rault, in aqueous solution, under the influence of light, at ordinary temperatures, it slowly changes into glucose; but this alteration does not take place in the dark. (*P. J. Tr.*, Jan. 1872, p. 643.)

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with lead monoxide. Boiled for a long time with aqueous solutions of potassa, lime, or baryta, the liquid becomes brown, formic acid is produced, and two new acids are generated,—one brown or black and insoluble in water, called *melassic acid*, the other colorless and very soluble, named *glucic acid.* Alkalies and the alkaline earths are said to lessen the rotatory power of sugar in relation to polarized light; but the sugar recovers its power when the alkali is saturated. (*Journ. de Pharm.*, 4e sér., iv. 314.) The action of acids and alkalies on cane sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids naturally existing in the saccharine juice have the effect of converting the cane sugar into uncrystallizable sugar, by which a loss of the former is sustained. The lime, by neutralizing these acids, prevents that result. An excess of lime, however, must be carefully avoided, as it injures the product of cane sugar in both quantity and quality. The change in sugar which precedes fermentation, namely, the conversion of cane sugar into the uncrystallizable kind, points to the necessity of operating on the juice before that process sets in; and hence the advantage of grinding canes immediately after they are cut, and boiling the juice with the least possible delay.

Molasses is of two kinds, the West India and sugar-house. *West India molasses* is a black ropy liquid, of a peculiar odor and sweet empyreumatic taste. When mixed with water and with the skimmings of the vessels used in the manufacture of sugar, it forms a liquor which, when fermented and distilled, yields *rum.* *Sugar-house molasses*, *golden drips*, or *grocer's syrup* is thicker than the West India molasses, and has a different flavor; as found in commerce, it is largely adulterated with glucose. Its sp. gr. is about 1·4, and it contains about 75 per cent. of solid matter. Both kinds of molasses contain uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and coloring matter.

Diabetic Sugar. The sugar found in urine is almost exclusively dextrose, $C_6H_{12}O_6$. It may be recognized by its reducing action upon Trommer's solution or by Fehling's test, by its producing a yellow or brown color in contact with alkalies, slowly in the cold, rapidly on heating, by its uniting with phenylhydrazine to form a crystalline glucosazone, by its power of fermenting with yeast, and by its dextro-rotatory character. The tests for sugar in urine should always be preceded by tests for albumin, which latter, if present, should be removed by coagulation and filtration. Traces of sugar are said to be found normally in urine, but this never amounts

to more than ·01 per cent., while from 3 to 5 per cent. of reducing sugar is often found in the urine of persons suffering from diabetes mellitus.

Medical and Pharmaceutical Uses. As an aliment and condiment *cane* sugar is enormously used by all civilized and semi-civilized nations. As a hydrocarbon it is nearly equivalent to starch in its nutritive value, by its digestion largely adding to the fatty tissues of the body; but, as it contains no nitrogen, it is incapable of sustaining life by itself. It seems to be worked up in the alimentary canal with much more difficulty than other hydrocarbons, and its excessive use is very apt to lead to acid dyspepsia. *Glucose*, or *grape* sugar, on account of its lack of sweetness, is not much used as a food, but it exceeds in food-value cane sugar, on account of its being more readily digested.

As a demulcent, cane sugar has been used to some extent in *catarrhal affections*, especially of the respiratory tract, and Dr. S. A. Cartwright, of New Orleans (*Bost. Med. and Surg. Journ.*, vols. xlvii. and li.), affirms that the vapor of boiling cane-juice is of very great value in the treatment of *bronchitis* and *consumption*. According to Dr. S. Meslach, glucose, when given in doses of from six to six and a half ounces per day in the form of the concentrated syrup, acts as a powerful diuretic, and is very useful in the treatment of *cardiac dropsy*. If the kidneys be healthy, the glucose is said not to appear in the urine. The celebrated grape cure of Europe is said to act by virtue of the glucose in the grape.

As dextrose and also the sugar of diabetes polarize to the right, it was suggested that levulose, which polarizes to the left, might be taken by diabetic patients without injury, especially in view of the fact experimentally demonstrated by Minkowski (*Therap. Monatsh.*, 1892) that in dogs, after extirpation of the pancreas, levulose, given in moderate doses, is consumed in the system, not appearing in the urine. In clinical trials by Ebstein, by Hans von Hebra, by Leyden, and by other clinicians, levulose has been given in *diabetes* up to the amount of nearly two ounces a day, with the appearance of only a very small proportion of it in the urine.* As its sweetening powers are at least equal to those of cane sugar, it would appear to be an important addition to the dietetics of diabetes. Under the name of *diabetin* it has been largely advertised as a proprietary preparation.

Sugar is much used for the purposes of preserving meat, fish, fruit, etc. It is probable that it acts by producing a rapid exosmose of the fluids of the fermentative organisms, its diluted solution being in fact prone itself to undergo fermentative change. All the different kinds of sugar susceptible of the alcoholic fermentation have this power. (Dr. Louis Mandl, *Arch. Gén. de Méd.*, 5e sér., xvi. 49, Juillet, 1860.) In pharmacy, sugar is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, to preserve them from change, and to protect certain ferruginous preparations from oxidation. Accordingly, it enters into the composition of several mixtures, pills, and powders, of syrups and confections, and of all the troches. *Molasses* is used for forming pills, for which it is well fitted, preserving them soft and free from mouldiness, on account of its retentiveness of moisture and its antiseptic qualities.

SACCHARUM LACTIS. U. S., Br. Sugar of Milk.

$C_{12}H_{22}O_{11}.H_2O$; 359·16. (SĂC'ĊHĄ-RŬM LĂC'TĬS.) $C_{12}H_{22}O_{11}.H_2O$; 360.

"A peculiar, crystalline sugar obtained from the whey of cow's milk by evaporation, and purified by recrystallization." *U. S.* "A crystallized sugar, $C_{12}H_{22}O_{11},H_2O$, obtained from the whey of milk." *Br.*

Lactin, Milk Sugar; Lactose; Sucre de Lait, *Fr.*; Milchzucker, *G.*

Sugar of milk, or *lactose*, is found only in milk, of which it forms about 5 per cent. (*Boussingault.*) It is manufactured largely in Switzerland and the Bavarian Alps, especially from the whey left over in cheese-making. In preparing it, milk is first coagulated by the addition of a little diluted sulphuric acid, and the resulting *whey* boiled down to about one-fifteenth of its original bulk into a brown, viscid, sweetly saline mass, which is put into tubs, where, in from twenty-four to forty-eight hours, the sugar crystallizes in a bright yellow granular mass, constituting the so-called "sugar-sand," which is afterwards decolorized by animal charcoal and repeated crystallizations. (*Amer. Drug.*, Sept. 1884.) Within recent years the numerous "creameries" in the United States have produced milk sugar in such large quantities as a by-product that its importation from Switzerland has almost ceased.

* According to J. B. Haycraft, patients with chronic diabetes can destroy 50 Gm. of levulose per diem. In some acute cases a part of the levulose given is burnt up, a part is changed into dextrose, and a third part passes as such into the urine. Rabbits can convert levulose into glycogen, the glycogen so formed accumulating in the liver. (*Zeit. f. Physiol. Chem.*, 1894.)

Sugar of milk is a hard, somewhat gritty, white substance, crystallized in four-sided prisms, and possessing a slightly sweet taste and a neutral reaction. In commerce it usually occurs in cylindrical masses, in the axis of which is a cord, around which the crystals have been deposited. It is "soluble in about 6 parts of water at 15° C. (59° F.), and in $1_{\frac{1}{4}}$ part of boiling water; insoluble in alcohol, ether, or chloroform. The aqueous solution of Sugar of Milk is neutral to litmus paper. On adding to a few C.c. of a hot, saturated aqueous solution of Sugar of Milk an equal volume of sodium hydrate test-solution, and gently warming, the liquid will turn yellow and brownish-red. On the further addition of a few drops of copper sulphate test-solution, a brick-red precipitate will appear. If about 1 Gm. of powdered Sugar of Milk be sprinkled upon about 5 C.c. of cold sulphuric acid contained in a flat-bottomed capsule, the acid may acquire a greenish or reddish but no brown or brownish-black color within half an hour (absence of *cane sugar*)." *U. S.* "In crystals or in crystalline masses, grayish-white, hard, odorless, faintly sweet. Soluble in 7 parts of cold *water*, and in about 1 part of boiling *water*. It should not leave more than 0·25 per cent. of ash when incinerated with free access of air. 1 gramme dissolved in 10 cubic centimetres of *water* gives a red color with *solution of phenol-phthalein* after the addition of three drops of the *volumetric solution of sodium hydroxide* (limit of lactic acid)." *Br.* Experiments have shown that much of the milk sugar of commerce contains microorganisms which have resulted from the decomposition of animal constituents in milk, and the tests of the Pharmacopœias do not exclude such impurities. (*Drug. Circ.*, 1893, 250; *Bull. Pharm.*, 1893, v. 5; *P. J. Tr.*, 1894, 853.) Its sp. gr. is 1·54. It is not susceptible of the vinous fermentation by the direct influence of yeast; but after the action of dilute acids, which first convert it into a variety of glucose, it is capable of furnishing a spirituous liquor. It is well known that both mares' and cows' milk, after becoming sour, are capable of forming an intoxicating drink, by fermentation. By the action of nitric acid, sugar of milk is converted into mucic acid. When anhydrous it consists of $C_{12}H_{22}O_{11}$; when crystallized, of $C_{12}H_{22}O_{11} + H_2O$. (Staedeler and Krause.) These formulas make anhydrous sugar of milk isomeric with cane sugar. Sugar of milk, when treated with weak sulphuric acid, is inverted or changed into a mixture of *galactose* and *dextrose*, both of the formula $C_6H_{12}O_6$. The galactose crystallizes in fine needles, fusing at 163° C. (325·4° F.).

Sugar of milk has been strongly recommended as a non-nitrogenous, bland article of diet in *consumption* and other *wasting diseases*, especially when there is extreme irritability of the stomach. According to Dr. S. Meslach, Dr. Zavadsky, and Prof. Germain Sée, it is an active hydragogue diuretic, which may often be used with great advantage in the treatment of *cardiac dropsy*. If the kidneys be sound, the lactose is said not to appear in the urine. It has been given by the authorities quoted in doses varying from three-quarters of an ounce to six ounces a day, administered in concentrated syrup or in milk.

SALICINUM. U. S., Br. Salicin.

$C_{13}H_{18}O_7$; 285·33. (SĂL-Ĭ-CĪ'NŬM.) $C_{13}H_{18}O_7$; 286.

"A neutral principle obtained from several species of Salix and Populus (nat. ord. Salicaceæ." *U. S.* "A crystalline glucoside, $C_6H_{11}O_5.O.C_6H_4.CH_2OH$, obtainable from the bark of various species of Salix, and of Populus." *Br.*

The discovery of salicin is claimed by Buchner, of Germany, and Fontana and Rigatelli, of Italy; but M. Leroux, of France, deserves the credit of having first accurately investigated its properties. The following is Merck's process for its extraction. A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colorless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid; while a portion of the oxide is dissolved in combination probably with the salicin. To separate this portion of oxide, sulphuric acid is first added, and then barium sulphide, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. (*Turner's Chemistry.*) Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with eight ounces of ivory-black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory-black, and crystallizing. Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix helix*, and

Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may probably be obtained from any of the willow barks having a bitter taste. Braconnot procured it from various species of Populus, particularly *P. tremula*, or European aspen. When pure, it is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavor of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and oil of turpentine. It neutralizes neither acids nor salifiable bases, and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright-red color, and producing a new compound called *rutulin*. It is officially described as in "colorless, or white, silky, shining crystalline needles, or a crystalline powder, odorless, and having a very bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 28 parts of water, and in 30 parts of alcohol; in 0·7 part of boiling water, and in 2 parts of boiling alcohol; almost insoluble in ether or chloroform. When heated to 198° C. (388·4° F.), Salicin melts, yielding a colorless liquid which, on cooling, congeals to a crystalline mass. Upon ignition, it is consumed, leaving no residue. Salicin is neutral to litmus paper. On heating a small portion of Salicin, in a test-tube, until it turns brown, then adding a few C.c. of water, and afterwards a drop of ferric chloride test-solution, a violet color will be produced. Cold, concentrated sulphuric acid dissolves Salicin with a red color; the solution, after the addition of water, becomes colorless, and deposits a dark-red powder insoluble in water or alcohol. On heating a small portion of Salicin with 1 C.c. of potassium dichromate test-solution and 2 C.c. of sulphuric acid, the odor of salicylic aldehyde (or of oil of meadow-sweet, *Spiræa ulmaria* Linné, nat. ord. *Rosaceæ*) will become noticeable. The aqueous solution of Salicin is not precipitated by tannic or picric acid, nor by mercuric potassium iodide test-solution (absence of, and difference from, *alkaloids*)." *U. S.* "Colorless shining trimetric tabular crystals, with a very bitter taste. Soluble in 28 parts of cold *water* or 60 parts of *alcohol* (90 per cent.); insoluble in *ether*. Colored red by *sulphuric acid*. A small quantity heated with a little *potassium bichromate*, a few drops of *sulphuric acid*, and some *water*, yields salicylic aldehyde, recognizable by its odor of meadow-sweet. The crystals melt when heated, and evolve salicylic aldehyde. On heating to redness in air they leave no residue (absence of mineral impurity)." *Br.* It belongs to the class of glucosides, being resolved by boiling with diluted hydrochloric and sulphuric acids into grape sugar and *saligenin*, according to the reaction $C_{13}H_{18}O_7 + H_2O = C_6H_{12}O_6 + C_7H_8O_2$. Saligenin, which is ortho-oxybenzyl alcohol, $C_6H_4(OH)CH_2OH$, is converted by further boiling with dilute acids into a resinous body, *saliretin*, $C_{14}H_{14}O_3$. Nitric acid produces with salicin at first two principles called respectively *helicin*, $C_{13}H_{16}O_7$, and *helicoidin*, $C_{26}H_{34}O_{14}$, and afterwards picric and oxalic acids. (*Journ. de Pharm.*, xxx. 43.) Distilled with potassium bichromate and sulphuric acid, salicin yields, among other products, a volatile oleaginous liquid, identical with one of the components of oil of spiræa, and recognized as *salicyl aldehyde*, $C_7H_6O_2$ (*salicylous acid*), while saligenin, $C_7H_8O_2$, is the alcohol, and salicylic acid, $C_7H_6O_3$, the acid corresponding. The synthesis of salicin has been effected by Michael (*A. J. P.*, 1879, 492), who obtained first helicin by the reaction of acetochlorhydrose and salicyl aldehyde, and, by the action of nascent hydrogen upon this, salicin.

Medical Properties and Uses. Salicin probably acts upon the stomach as a simple bitter, and after absorption as a feeble and uncertain form of salicylic acid, since it is rapidly decomposed in the system, the products of its change appearing in the urine fifteen to thirty minutes after the ingestion of a single dose. The elimination is partly as salicin, partly as salicylic acid, partly as a salicyluric acid, and partly as saligenin. It has been highly recommended as a substitute for salicylic acid in *rheumatism* by Maclagan and others, but later reports are not so favorable; and if, as believed by Senator, the activity of salicin depends upon its conversion in the blood into salicylic acid, it is plain that its action should be slower and more uncertain than that of the acid. The dose is twenty to thirty grains (1·3 to 1·95 Gm.) every three hours, administered in syrup or cachet. Salicin has been used to some extent as an antiperiodic, and appears to possess some influence over slight *malarial disorders*, though vastly inferior to the cinchona alkaloids. One or two drachms may be given in the intermission.

SALOL. U. S., Br. Salol. [Phenyl Salicylate.]

$C_6H_5C_7H_5O_3$; 213·47. (SĂL'ŎL.)

"The salicylic ether of phenol." *U. S.* "Salol, or phenyl salicylate, $C_6H_4.OH.COO.C_6H_5$, is prepared by the interaction of salicylic acid and phenol, or of their sodium salts with phosphoryl chloride or carbonyl chloride." *Br.*

Salol was first produced by Prof. Nencki, of Basel, and introduced to the medical profession by Dr. Sahli, of the same place. It is prepared by heating salicylic acid with phenol in the presence of phosphorus pentachloride or phosphorus oxychloride; the action dehydrates and withdraws the elements of water, and unites the phenyl group with the salicylic acid radical. According to Ernert, nearly the theoretical yield of salol may be obtained by heating salicylic acid to a temperature between 160° C. and 240° C., and preventing the access of air while water is being disengaged; it is probable that salicylic anhydride is formed, and the phenol resulting from its decomposition combines with unaltered salicylic acid to produce salol. It is described as "a white, crystalline powder, odorless, or having a faintly aromatic odor, and almost tasteless. Permanent in the air. Almost insoluble in water; soluble in 10 parts of alcohol at 15° C. (59° F.); very soluble in boiling alcohol; also soluble in 0·3 part of ether, and readily in chloroform, and in fixed or volatile oils. When heated to 42°–43° C. (107·6°–109·4° F.), Salol melts. When heated on platinum, it takes fire, and is consumed, leaving no residue. Salol is neutral to litmus paper moistened with alcohol. On warming a small portion of Salol with enough sodium hydrate test-solution to dissolve it, and then supersaturating the liquid with hydrochloric acid, salicylic acid will separate, and the odor of phenol will become perceptible. In an alcoholic solution of Salol, bromine water, added in excess, produces a white precipitate. On adding a few drops of dilute ferric chloride test-solution, made by diluting the test-solution with 20 volumes of water, to 10 C.c. of an alcoholic solution (1 in 50) of Salol, the liquid will acquire a violet tint. If, however, a few drops of the alcoholic solution of Salol be added to 10 C.c. of the diluted ferric chloride test-solution, a whitish cloudiness, but no color, will be produced on shaking. On shaking 1 Gm. of Salol with 50 C.c. of water, the filtrate should not be affected by ferric chloride test-solution, previously diluted with 20 volumes of water (absence of *uncombined carbolic* or *salicylic acid*); nor by barium chloride test-solution (absence of *sulphate* or *phosphate*); nor by silver nitrate test-solution (absence of *chloride*)." *U. S.* "Colorless crystals having a faint aromatic odor and very little taste. Almost insoluble in *water*, soluble in 10 parts of cold *alcohol* (90 per cent.), very soluble in boiling *alcohol* (90 per cent.), also soluble in one-third part of *ether* or *chloroform*, and in fixed and volatile oils. Melting point 107·6° to 109·4° F. (42° to 43° C.). An alcoholic solution gives a white precipitate with *solution of bromine*. A violet coloration is produced on adding a few drops of dilute *test-solution of ferric chloride* to the alcoholic solution. On melting together Salol and *sodium hydroxide*, and then acidulating with *hydrochloric acid*, a white precipitate is produced and phenol is evolved. *Water* which has been shaken with Salol should not be affected by *test-solution of ferric chloride* (absence of free salicylic acid) and should yield no reaction with the tests for sulphates or chlorides. The alcoholic solution of Salol should be neutral to *litmus*." *Br.*

Medical Properties and Uses. In the small intestine salol is broken up by the pancreatic juice, and yields about thirty-six per cent. of phenol and sixty-four per cent. of salicylic acid. The completeness and rapidity of this action depend upon the amount of salol ingested and of the alkaline juice in the intestines. The change is, however, sufficient, when salol is freely given, for the production of salicylic acid intoxication, and for the blacking of the urine with educts from carbolic acid. Because this change occurs in the intestines somewhat slowly, the remedy is valuable as an internal antiseptic in the treatment of *typhoid fever*, in fermentative *dyspepsia*, and in various diseases of the intestinal canal. It has been largely used in rheumatism as a substitute for salicylic acid, but it is much less prompt and certain in its action than is that remedy. Moreover, on account of the large proportion of phenol which it contains, it is much more dangerous than the corresponding dose of salicylic acid. Hesselbach has shown that it is prone to affect the secreting structure of the kidneys, and two fatal cases of poisoning by it have been reported. (*Lancet*, May, 1891.) It is especially dangerous when the kidneys are diseased. Salol has also been used externally as a substitute for iodoform, and internally, according to the method of Ewald, for the purposes of gastric diagnosis. (See H. C. Wood's *Therapeutics*.) Dose, from fifteen to thirty grains (0·97–2 Gm.).

SALVIA. U. S. Salvia. [Sage.]

(SĂL'VĮ-Ą.)

"The leaves of Salvia officinalis, Linné (nat. ord. Labiatæ)." *U. S.*

Sage; Folia (Herba) Salviæ, *P. G.*; Sauge officinale, Sauge, *Fr.*; Salbei, Salbeiblätter, *G.*; Salvia, *It.*, *Sp.*

Salvia officinalis. L. *Sp. Pl.* (1753) 23; Willd. *Sp. Plant.* i. 129; *B. & T.* 206. Common garden sage is a perennial plant, about two feet high, with a quadrangular, pubescent, branch-

ing, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green color, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple, and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and provided with ovate, acute, deciduous bracts. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.*

Sage grows spontaneously in the south of Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and color of their flowers, but all possessing the same medical properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves are officially described as "about 5 Cm. long, petiolate, ovate-oblong, obtuse or subacute at the apex, rounded or somewhat heart-shaped at the base, finely crenulate, thickish, wrinkled, grayish-green, soft-hairy and glandular beneath; odor aromatic; taste aromatic, bitterish, and somewhat astringent." *U. S.*

Both these and the flowering summits have a strong, fragrant odor, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (*Journ. Chem. Soc.*, 37, p. 678) found it to contain a terpene boiling at 156° C. (312·8° F.), another boiling at 171° C. (339·8° F.), *thujone*, $C_{10}H_{16}O$, a liquid boiling at from 197°–203° C., and ordinary camphor, $C_{10}H_{16}O$. In the fresh oil the first terpene predominates. On standing, the amount of *thujone* increases, and then the camphor. The oil from English leaves contains also a sesquiterpene, $C_{15}H_{24}$, of the boiling point 260° C. (500° F.). Wallach (*Ann. der Ch. und Phar.*, 1889) states that the first portions contain *pinene* and *cineol*, but the greater portion consists of *thujone*, $C_{10}H_{16}O$ (formerly called *salviol*). Ferrous sulphate strikes a black color with their infusion.

Medical Properties and Uses. Sage unites slightly tonic, astringent, and aromatic properties. By the ancients it was highly esteemed; it is at present little used, except as a condiment, but has been given in *dyspepsia*, also for *colliquative sweats*. The dose of the powdered leaves is from twenty to thirty grains (1·3–1·95 Gm.). Dose of the infusion (℥i to Oj of boiling water), two fluidounces (60 C.c.). According to Cadéac and Meunier (*Lyon Méd.*, May, 1891), the volatile oil of sage is a violent epileptiform convulsant, resembling in its action the oil of absinthe, but less powerful.

* The medicinal properties of the official sage are probably shared by various species of the genus. *S. pratensis*, *S. Æthiopis*, *S. glutinosa*, and *S. sclarea*, or *clarry*, have been officially recognized in Europe, but are less agreeable than is *S. officinalis*, and are not much used: the leaves of *S. sclarea* are said to be introduced into wine in order to impart to it a muscadel taste. Dr. A. Comstock (*Therap. Gaz.*, 1887, 660) states that the infusion of the Rocky Mountain sage (probably *S. lanceolata*, Willd.) is, when hot, a powerful diaphoretic, and, when cold, an active diuretic. It is also affirmed to be distinctly tonic, and of great value in the treatment of the malarial, rheumatic, and exanthematous fevers of the country. The dose of the fluid extract is half a drachm. It would appear also that the seeds of various species of the genus are farinaceous, mucilaginous, and capable of being used as food. The stockmen of the West attribute very great fattening properties to the ordinary sage of the Plains, whose ripened tops are freely eaten by the cattle. Under the name of *Chia* the seeds of one or more species of sage are employed in Mexico, Arizona, and New Mexico by the Mexicans and Indians as food. Probably the most important of the chia-yielding sages is the *S. columbaria* (see *Report U. S. Geogr. Surveys, 100th Merid.*, vol. vi. 48), the seeds of which are called *Chia-Pinoli*; it grows in Mexico as well as in New Mexico, Arizona, Nevada, and California. *S. chia* is described in the last edition of the *Farmacopea Mexicana* as a new species, yielding chia, but M. Mariano Báscena affirms (*La Naturaleza*, 1881) that the common chia-yielding sage of Mexico is *S. polystachya*, whilst *Chia azul* is yielded by *S. patens*. Guibourt is probably in error in ascribing chia to *S. hispanica*. The chia seeds are used not only when crushed as food and for the making of mucilaginous poultices, but also for the preparation of a mucilaginous drink, prepared by adding a teaspoonful of the seed to a tumblerful of cold water, allowing it to stand for half an hour, sweetening and flavoring to taste. They are described as follows. "The seed is a small one, about $\frac{1}{16}$ inch in length and $\frac{1}{24}$ inch in width; oblong-ovate, somewhat flattish, nearly cylindrical, both ends rounded and slightly tapering; the thinner end has a small, dark line, forming a slight projection, which is the eye of the seed, and this, when exposed to moisture, opens in a star-shaped or scalloped manner, emitting the growing embryo. Below this eye are oil-cells. The seed is smooth and glossy, and is surrounded by a transparent epithelium, swelling very largely when in water. The testa is darkish gray, striated with dark brown lines, running diagonally, and dotted, forming a very beautiful variegated surface; when pressed or crushed under a spatula it bursts at the hilum, exposing the cotyledons and the oil-cells, leaving an oily stain upon paper. Internally the testa is dark, grayish brown, perfectly smooth, glossy, and devoid of the external variegations or striæ. It contains the embryo, with the radical pointing towards the hilum, and a white, mucilaginous substance much resembling unrendered fat." (*A. J. P.*, May, 1882, 227–229.) The European species, *Salvia verticillata*, Willd., *S. Verbenaca*, Linn., *S. horminum*, Linn., and *S. viridis*, Linn., all indigenous to Central or Southern Europe, are also noted for the mucilaginous character of their seeds, and have on this account been employed to remove foreign substances from the eye, just as linseed is used with us.

SAMBUCUS. U. S. (Br.) Elder.

(SĄM-BŪ'CŬS.)

"The flowers of Sambucus Canadensis, Linné (nat. ord. Caprifoliaceæ)." *U. S.* "The flowers of Sambucus nigra, Linn., separated from the stalks." *Br.*

Sambuci Flores, *Br.;* Elder Flowers; Fleurs de Sureau, Sureau, *Fr.;* Hollunder, Fliederblumen, *G.;* Sambuco, *It.;* Sauco, *Sp.*

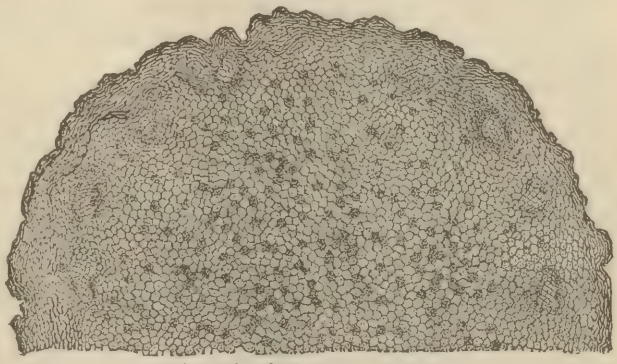
Sambucus canadensis. L. *Sp. Pl.* (1753) 269; Willd. *Sp. Plant.* i. 1494; *B. & T.* 138. Our indigenous *common elder* is a shrub from six to ten feet high, with a branching stem, covered with a rough gray bark, and containing a large spongy pith. The small branches and leaf-stalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of three or four pairs of oblong-oval, acuminate, smooth, shining, deep-green leaflets; the veins of the under surface are somewhat pubescent. The flowers are small, white, and disposed in loose cymes; the cream-colored corolla is wheel-shaped, with five stamens on the tube. The berries are small, globular, and deep purple when ripe. The shrubs grow in low, moist grounds, along fences, and on the borders of small streams, in all parts of the United States, from Canada to the Carolinas, and westward as far as Texas. It flowers from May to July, and ripens its fruit early in autumn. The flowers, which are official, have an aromatic though rather heavy odor. The berries as well as other parts of the plant are employed, in domestic practice, for the same purposes as the corresponding parts of the European elder, to which this species bears a close affinity.

Sambucus nigra. Willd. *Sp. Plant.* i. 1495; *B. & T.* 137. The common elder of Europe differs from the American most obviously in its size, which approaches to that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are narrower. The flowers are small, whitish, and in five-parted cymes. The ovary consists of but three carpels, there being five cells in *S. canadensis*, L. The berries are larger, globular, and blackish purple when ripe.* G. De Sanctis (*Gazz. Chim. Ital.*, 1895, xxv. 1, vol. xlix.) obtained coniine from the leaves and stems of *Sambucus nigra.*

"The flowers are, when fresh, about 5 Mm. broad, and after drying shrivelled; calyx superior, minutely five-toothed; corolla originally cream-colored, after drying pale brownish-yellow, wheel-shaped and five-lobed, with five stamens on the short tube; odor peculiar; taste sweetish, somewhat aromatic and bitterish. The peduncles and pedicels of the inflorescence should be rejected." *U. S.* The flowers yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence and an appreciable portion of ammonia. The *berries* are nearly inodorous, but have a sweetish, acidulous taste, dependent on the presence of saccharine matter and malic acid. Their expressed juice is susceptible of fermentation, and forms a vinous liquid used in the north of Europe. It is colored violet by alkalies, and bright red by acids; and the coloring matter is precipitated blue by lead acetate. The *inner bark* is without smell. Its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and the epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produce brisk vomiting and purging. (*Annal. der Pharm.*, xxxi. 262.) The bark, analyzed by Kramer, yielded an acid called by him *viburnic acid* (which has proved to be identical with *valerianic acid*), traces of volatile oil, albumen, resin, fat, wax, chlorophyll, tannic acid, grape sugar, gum, extractive, starch, pectin, and various alkaline and earthy salts. (*Chem. Gaz.*, May, 1846; from *Archiv der Pharm.*) C. G. Traub found in the bark valerianic acid, volatile oil, fat, resin, tannin, sugar, and coloring matter. (*A. J. P.*, 1881, p. 392.) J. B. Metzgar made a partial examination of the fruit, and found sugar, gum, tannin, fat, and a resinous body. (*A. J. P.*, 1881, p. 553.) It was also examined by F. F. Lyons (*A. J. P.*, 1892, p. 1), who found 0·5 per cent. of a volatile oil, an amorphous yellow compound of a glucosidal character, and a tannin. The volatile oil of elder flowers was examined by W. J. Bush & Co. (*Chem. and Drug.*, 1897, 53.) It has the sp. gr. 0·827, and is solid at ordinary temperatures like oil of rose. The liquid portion possesses the fragrance of fresh elder blossoms.

* A fungus growing on this plant, called *fungus sambuci*, has been used as a local application in *conjunctivitis*. According to Steckel, it is capable of taking up from 9 to 12 times its weight of water. (*Neues Repert.*, xiii. 476, 1864.)

Medical Properties and Uses. The flowers are gently excitant and sudorific, but are seldom used. The berries are diaphoretic and aperient; and their inspissated juice has been used as an alterative in *rheumatism* and *syphilis* in doses of from one to two drachms (3·9–7·8 Gm.); also as a laxative in doses of half an ounce (15·5 Gm.) or more. The inner bark is a hydragogue cathartic, and in large doses emetic. It has been employed in *dropsy*, *epilepsy*, and as an alterative in various *chronic diseases*. An ounce may be boiled with two pints of water to a pint, and four fluidounces (118 C.c.) given for a dose. It is also used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been highly recommended in *dropsy* as a hydragogue cathartic, sometimes acting as an emetic, in the dose of a tablespoonful, repeated *pro re nata*. The fruits of the California species *S. glauca* and *S. racemosa* are said to be used as food by the Indians. According to Combemale, confirmed by Lemoine, the aqueous solution of the European elder, *S. nigra*, is a very active diuretic, also causing in the lower animals, when given in sufficient amount, a pronounced fall of temperature, pulse, and respiration. It was found very useful in *cardiac* and *renal dropsies*. The drug itself sometimes vomited and purged, but this effect never followed the use of the decoction.



SANGUINARIA. U. S. Sanguinaria. [Bloodroot.]

(SĂNG-GUĬ-NĀ'RĬ-Ą.)

"The rhizome of Sanguinaria Canadensis, Linné (nat. ord. Papaveraceæ), collected in autumn." *U. S.*

Puccoon, Tetterwort, Indian Paint; Sanguinaire, *Fr.*; Blutwurzel, *G.*

Sanguinaria canadensis. L. *Sp. Pl.* (1753) 505; Willd. *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.* i. 75; Barton, *Med. Bot.* i. 31; *B. & T.* 20. The *bloodroot*, or, as it is sometimes called, *puccoon*, is an herbaceous or perennial plant. The root (rhizome) is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown color on the outside, and brighter red within. It is furnished with numerous slender roots, and makes offsets from the sides, which succeed the old plant. From the end of the rhizome arise the scape and leaf-stalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channelled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish green on the upper surface, paler or glaucous on the under, and strongly marked by orange-colored veins. The scape is erect, round, and smooth, rising from a few inches to a foot, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The ovary is oblong and compressed, with a sessile, persistent stigma. The capsule is oblong, acute at both ends, one-celled, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-colored sap, which flows from every part when broken, but is of the deepest color in the rhizome. The bloodroot is one of the earliest and most beautiful spring flowers of the northern United States, growing abundantly in loose, rich soils and shady situations. After the fall of the flower the leaves continue to grow, and by the middle of summer have become so large as to give the plant an entirely different aspect. Except the seeds, all parts of the plant are active.

Sanguinaria, transverse section.

The dried rhizome is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, faintly annulated, much wrinkled and twisted, often furnished

with abrupt offsets and many short fibres, of a reddish-brown color externally, with a spongy uneven fracture, the surface of which is at first bright orange, or whitish, with numerous small red resin-cells, but becomes of a dull brown by long exposure. For an interesting microscopical description of the rhizome by Prof. E. S. Bastin, see *The Pharmacist*, 1885, p. 201. The color of the powder is a brownish orange-red. Sanguinaria has a faint narcotic odor, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. The late Dr. Dana, of New York, obtained from it an alkaloid, denominated by him *sanguinarine*, by infusing the finely powdered root in hot water or diluted hydrochloric or acetic acid, precipitating with ammonia water, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, treating the residue left upon the filter with alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist. New York*, ii. 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrine from celandine. This consists in forming a strong ethereal tincture of the root, passing through this hydrochloric acid gas, drying the precipitated hydrochlorate, which is insoluble in ether, dissolving it in hot water, filtering, precipitating by ammonia, drying the precipitate, dissolving it in ether, decolorizing by animal charcoal, precipitating by means of hydrochloric acid gas, and decomposing the hydrochlorate as before. (*Chem. Gaz.*, i. 145.) G. König (*A. J. P.*, 1891, p. 457) has reinvestigated the constituents of *S. canadensis* and given us a clearer understanding of them. He finds *chelerythrine*, which is present in greatest quantity, *sanguinarine*, *γ-homochelidonine*, and *protopine*. Chelerythrine crystallizes with a molecule of alcohol which is not separated at 150° C. Its formula is $C_{21}H_{17}NO_4$, and it is identical with the alkaloid extracted from *Chelidonium majus*. The salts are lemon-yellow. Sanguinarine has the formula $C_{20}H_{15}NO_4$, and is very similar to chelerythrine in its properties. It crystallizes with one-half molecule of H_2O, and melts at 211° C. Its salts are red. The base named *γ*-homochelidonine is probably identical with that separated by Selle from *Chelidonium majus*, and its formula is $C_{22}H_{21}NO_4$. The fourth alkaloid, protopine, has been prepared from *Chelidonium majus*, from *Sanguinaria canadensis*, and from opium, all three of the specimens being identical. Its formula is $C_{20}H_{17}NO_5$, and it melts at 204° C. The virtues of the root are said to be rapidly deteriorated by time. Mr. Thos. M. Newbold extracted from sanguinaria a non-volatile liquid acid (*sanguinarinic acid*) (*A. J. P.*, 1866, p. 496), which L. C. Hopp has shown to be a solution of impure citric and malic acids.

Medical Properties and Uses. Sanguinaria is an acrid emetic, with stimulant narcotic powers. In small doses it excites the stomach and accelerates the circulation; more largely given, it produces nausea and consequent depression of the pulse; and in the full dose it occasions active vomiting. It is also expectorant, and is said to be emmenagogue. The effects of an overdose are violent emesis, a burning sensation in the stomach, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. (For fatal cases, see *Am. Journ. of Med. Sci.*, N. S., ii. 506.) Snuffed up the nostrils, bloodroot excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been used in various diseases, but is at present very rarely employed, except as a stimulant expectorant in *chronic bronchitis* or in the advanced stages of the acute disorder.

The emetic dose is from ten to twenty grains (0·65–1·3 Gm.), preferably given in pill, in consequence of the great irritation of the throat produced by the powder when swallowed. The expectorant dose is from one to five grains (0·065–0·33 Gm.), repeated more or less frequently according to the effect desired, but the official tincture is better than the crude drug.

Dr. Wm. Tully found the alkaloid *sanguinarine*, in large doses, to produce vertigo, dilatation of the pupil, a haggard expression of the face, nausea, coldness of the extremities, cold sweats, and diminished frequency with irregularity of the pulse. The late Prof. R. P. Thomas, of Philadelphia, who experimented with it on himself and others, gave the following statement of its powers. In doses varying from one-twelfth to one-eighth of a grain (0·005–0·008 Gm.) it acted as an expectorant, without disturbing the stomach. One-sixth or one-fourth (0·01–0·016 Gm.) of a grain, given every two or three hours, generally produced nausea, and sometimes vomited. Half a grain (0·03 Gm.) in solution, given at intervals of ten minutes, almost invariably vomited after the second or third dose. Under the influence of one-eighth or one-sixth (0·008–0·01 Gm.) of a grain, given every three hours, for two days or more, the pulse was generally reduced from five to fifteen beats in the minute. He found no alterative effect, and none of any kind directly upon the liver. (*Proc. of Amer. Med. Assoc.*, 1863, p. 219.) Dr. Robert Meade Smith finds that the alkaloid in large doses produces in mammals vomiting,

purging, collapse, convulsions, and death from asphyxia, the convulsions being spinal, but associated with loss of reflex activity and depression of the spinal motor centres. The same authority states that moderate doses cause a rise of arterial pressure by stimulation of the vaso-motor centre, whilst toxic doses depress the pressure, partly by a direct action upon the heart, partly by paralyzing the vaso-motor centres. Hans Meyer (*Arch. f. Exper. Path. u. Pharm.*, xxix.) found in the frog that sanguinarine first stimulates and then paralyzes spinal-motor ganglia; on the blood-pressure it acted much as described by Dr. Smith.*

SANTALUM RUBRUM. U. S. (Br.) Red Saunders.

(SĂN'TA-LŬM RŪ'BRUM.)

"The wood of Pterocarpus santalinus, Linné filius (nat. ord. Leguminosæ)." *U. S.* "The heart-wood of Pterocarpus santalinus, Linn. fil." *Br.*

Pterocarpi Lignum, *Br.;* Red Sanders Wood; Red Sandal Wood; Lignum Santalinum Rubrum; Santal rouge, *Fr.;* Santelholz, Rothes Santelholz, *G.*

Pterocarpus santalinus. L. *Sp. Pl.* (1781) 318; Willd. *Sp. Plant.* iii. 906; Woodv. *Med. Bot.* 430, t. 156; *B. & T.* 82. This is a large tree, with alternate branches, and petiolate ternate leaves, each simple leaf being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the *vexillum* is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the *alæ* spreading with their edges apparently toothed, and the *carina* oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. It is said that it is everywhere rare, and that plantations of it are being formed. Its wood is the official *red saunders*, though there is reason to believe that the products of other trees are also sold by the same name.

The wood comes in heavy, irregular, roundish or angular billets of various size and thickness, externally brown from exposure, internally of a deep blood-red color, on transverse section variegated with zones of a lighter red. The structure is heavy, compact, and fibrous. In the pharmacies red saunders is usually kept in the shape of small chips, or raspings, or coarse powder, of a deep reddish-brown color, slightly astringent in taste, and when rubbed of a faint peculiar odor. It has little smell or taste. It imparts a red color to alcohol, ether, and alkaline solutions, but not to water; and a test is thus afforded by which it may be distinguished from some other coloring woods. The alcoholic tincture produces a deep violet precipitate with ferrous sulphate, a scarlet with mercuric chloride, and a violet with the soluble salts of lead. The coloring principle, which was separated by Pelletier and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. Weyermann and Haeffely have found it to possess acid properties, and give it the formula $C_{15}H_{14}O_5$. (*Ann. d. Ch. und Pharm.*, 74, p. 226.) Weidel (*Wien. Akad. Ber.*, lx. p. 388), by extracting the red saunders with caustic potash, precipitating with hydrochloric acid, and again extracting from the purified precipitate with ether, obtained a colorless crystalline principle, which he calls *santal*, $C_8H_6O_3 + \frac{1}{2}H_2O$.

Cazeneuve and Hugonneng (*Comptes-Rendus*, 104, 1722–1725) have described two crystalline principles which they have extracted from red saunders, *pterocarpin*, $C_{20}H_{16}O_6$, and *homopterocarpin*, $C_{24}H_{24}O_6$, of which the former fuses at 152° C. and the latter at from 82°–86° C. The wood has no medical virtues, and is employed solely for the purpose of imparting color.

* *Acetum Sanguinariæ, U. S.* 1880. *Vinegar of Sanguinaria.* (*Vinaigre de Sanguinaire*, Fr.; *Blutwurzel-Essig*, G.) "Sanguinaria, in No. 30 powder, *ten parts* [or one and three-fourths ounces av.]; Diluted Acetic Acid, *a sufficient quantity*, To make *one hundred parts* [or one pint]. Moisten the powder with *five parts* [or one fluidounce] of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until *one hundred parts* [or one pint] of filtered liquid are obtained." *U. S.* 1880. Vinegar of Sanguinaria may also be prepared by macerating the powder in one pint of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper. It is efficient, and of a deep-red color. On standing, a deposit is always noticed upon the sides of the vessel containing it, and the color pales: the cause of this is unknown, as, according to the late Prof. Procter, the change is independent of the sanguinarine acetate, which is formed in the process. (*A. J. P.*, May, 1864, p. 210.) A syrup may be formed from this vinegar by the addition of sugar, as in the syrup of squill. The dose of the vinegar of bloodroot as an emetic is three or four fluidrachms (11·25 or 15 C.c.); as an alterative and expectorant, from fifteen to thirty drops or minims (0·9–1·9 C.c.). It has been used as a local remedy in *ringworm* and other *cutaneous diseases*, and has been found by Dr. R. G. Jennings efficient as a gargle in the *sore throat of scarlet fever.*

SANTONICA. U. S. Santonica. [Levant Wormseed.]

(SAN-TŎN'I-CA.)

"The unexpanded flower-heads of Artemisia pauciflora, Weber (nat. ord. Compositæ)." *U. S.*

European Wormseed; Santonici Semen, Semen Cynæ, Semen Contra; Flores Cinæ, *P. G.;* Semen Sanctum; Barbotine, Semencine, *Fr.;* Wurmsamen, Zittwersamen, *G.*

Artemisia maritima, L. *Sp. Pl.* (1753) 846,* is a small, semi-shrubby perennial, from whose oblique, knotted rootstalks arise numerous leafy shoots and flowering stems. The glabrous and woody stems bear on their many branches numerous small (one inch long) bi- to multipinnatifid leaves, whilst the leaves of the flowering stems are very minute, the upper ones simple. The flower-heads are small, numerous, one-tenth of an inch long, with from twelve to eighteen involucral scales, and from three to five flowers. The plant varies very greatly, and several species have been been made out of its varieties. The form whose floral buds are said to resemble most closely the commercial drug has been named *A. cina* by Berg and Schmidt (t. 29, c.), and *A. pauciflora* by Weber (*Steehm. de Artem.*, 1775, 26). Following Bentley and Trimen, 157, the revisers of the recent U. S. P. have recognized the specific distinctness of the variety *pauciflora* and adopted the name given by Weber; but the propriety of this seems doubtful, since the researches of the Russian botanists Besser and Ledebour indicate that the forms are not specifically distinct, but are merely varieties of one plant, which has an extremely wide distribution in the northern hemisphere; from the old marshes of the British Islands it has spread along the coasts of the Baltic and the Mediterranean and eastward over the saline soils in Hungary, through Southern Russia and Central Siberia, to Chinese Mongolia. Nor do Engler and Prantl recognize the species *A. pauciflora*, Weber. They consider with Willkomm that the origin of wormseed is *A. cina*, Berg. (See also *P. J. Tr.*, 1872, 762.) In European commerce there are two kinds of wormseed, one called *Aleppo*, *Alexandria*, or *Levant wormseed*, the other *Barbary wormseed.* The *Barbary wormseed* is thought by some to be derived from *Artemisia judaica*, by others from *A. sieberi*† of Besser (*A. glomerata* of Sieber), and from *A. ramosa* (C. Smith), all of which grow in Palestine and Arabia. It consists of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or are in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. It is, moreover, lighter and more colored than the latter. Its smell and taste are the same. The Levant wormseed is the santonica of the two Pharmacopœias. It is officially described as "from 2 to 4 Mm. long, oblong-ovoid, obtuse, smooth, somewhat glossy, grayish-green, after exposure to light, brownish-green, consisting of an involucre of about 12 to 18 closely imbricated glandular scales with a broad midrib, enclosing four or five rudimentary florets; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter." *U. S.* Astolfi (*Pharm. Zeit.*, 1893, 333) gives the following test for recognizing adulteration of santonica. 1 Gm. of the suspected drug is finely pulverized and then agitated with 10 C.c. of absolute alcohol; the whole is then heated to boiling, filtered, a piece of caustic potash is added to the filtrate, which is then heated. If the drug be pure, the liquid will acquire a pronounced red color; if falsified, the color will be yellow; and if no santonica be present, the liquid will be colored but faintly, if at all.‡

Of late years most of the wormseed of commerce has come from the steppes of the northern portion of Turkestan to the great Nizhnee-Novgorod fair, whence it finds its way to Moscow and Western Europe. The export from this region is said to have reached 1600 tons annually, but has largely declined, because the conquest of Turkestan by Russia led to the establishment in Orenburg of large factories for the manufacture of santonin, which is now sent thence into

* Messrs. Heckel and Schlagdenhauffen (*Comptes-Rendus*, 804) find that *Artemisia gallica* contains santonin, essential oil, and probably an alkaloid.

† *A. sieberi* is in all probability, however, but a variety of the very variable *A herba-alba*, which is used by the Arabs under the name of "*chili*" as a vermifuge, and in which M. Battandier found two resins and a large quantity of essential oil, but no santonin.

‡ For a method of valuing santonica, by Dragendorff, see *Proc. A. P. A.*, xxvi. 229.

Ehlinger's Process for valuing Santonica. Five parts of santonica and one part of milk of lime were boiled for two hours in a considerable quantity of dilute alcohol and the liquid poured off after cooling: this treatment was repeated at least twice more, and the alcohol was then distilled off from the united extracts. The residual liquid was then saturated in the cold with carbonic acid, filtered off from the precipitate after standing some hours, and the filtrate evaporated to dryness. The residue was triturated with animal charcoal and alcohol of specific gravity 0·935, and the paste rinsed into a retort, where it was digested with a measured quantity of alcohol. After boiling, the contents of the retort were thrown on a filter, washed with hot alcohol, and the alcohol driven off from the filtrate, from which, after some hours, crystals of santonin separated. (*P. J. Tr.*, 1886, p. 449.)

commerce. The yearly consumption of santonin throughout the world is estimated at about twenty-five tons, and of this at least twelve tons are produced in the factories just spoken of. The santonin in the plants is said to reach its maximum proportion in July and August, and to disappear immediately after the flowering.

Wormseed contains a volatile oil, but it owes its efficiency to *santonin.* (See *Santoninum.*) According to Merck, the mother-liquors in the manufacture of santonin from the seeds of *Artemisia maritima* yield a crystalline principle, $C_{15}H_{18}O_4$, which has been named *artemisin.* It is freed from santonin by recrystallization from chloroform. It melts at 200° C., gradually turns yellow in the air, and is more readily soluble in water and in dilute alcohol than is santonin. It gives a fugitive carmine red color when heated with aqueous or alcoholic soda, and is apparently a *hydroxy-santonin.* (*P. J. Tr.*, 1896, 484.) The essential oil of wormseed, according to Wallach (*Ann. der Ch. und Pharm.*, 225, 314, and 227, 277), is mostly made up of *cineol*, $C_{10}H_{18}O$, which is isomeric with borneol, and seems to be identical with the cajuputol of cajuput oil, together with some *dipentene.* Wormseed is rarely used in this country in substance. The dose is from ten to thirty grains (0·65–1·95 Gm.).

SANTONINUM. U. S., Br. Santonin.

$C_{15}H_{18}O_3$; 245·43. (SĂN-TŌ-NĪ'NŬM.) $C_{15}H_{18}O_3$; 246.

"A neutral principle obtained from Santonica. Santonin should be kept in dark amber-colored vials, and should not be exposed to light." *U. S.* "A crystalline principle, $C_{15}H_{18}O_3$, prepared from santonica, the dried unexpanded flower-heads or capitula of Artemisia maritima, var. Stechmanniana, Besser." *Br.*

The U. S. P. of 1890 and the Br. Ph. 1898 very properly omit processes for the preparation of Santonin. (See *U. S. D.*, 17th ed., 1191.)

By the U. S. process of 1870, which was taken from Wittstein's *Pharmaceutical Chemistry*, the santonica is first exhausted by digestion with diluted alcohol, in connection with slaked lime,—the latter substance being employed to combine with the santonin and remove coloring matter which might subsequently embarrass the proceedings. The tincture thus obtained, having been reduced by the distillation of the alcohol to little more than an aqueous solution, is filtered and treated with acetic acid in slight excess, by which the santonin is separated from the lime which holds it in solution, and, being itself insoluble, is gradually deposited in a crystalline state. The remainder of the process is intended simply to obtain the crystals free from coloring matter, and otherwise pure.

The British (1885) process, which is that of M. Mialhe somewhat modified (*P. J. Tr.*, 1864, 635), spares the expenditure of alcohol in the exhaustion of the santonica, by boiling it originally with water in connection with lime, and differs also from the preceding in precipitating the santonin by hydrochloric instead of acetic acid. The purification is effected in the same manner, except that solution of ammonia is employed in the washing, probably to remove the last trace of acid. Wormseed of Aleppo yields from 1·2 to 1·4 per cent. of santonin. (*Journ. de Pharm.*, Mars, 1864, p. 241.) It has been intimated to us that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe, and that the process for preparing santonin is probably facilitated thereby, the affinity of the oil for the santonin making the latter more difficult of purification.

Santonin has been furnished at lower prices since the erection of a factory in Tschemkend, Turkestan, where the Levant wormseed can be furnished cheaply: the process used there is to treat the wormseed with milk of lime; the calcium santonate formed is next treated with soda and carbonic acid; the sodium santonate is then decomposed by sulphuric acid. The acid liquid, on refrigeration, lets fall the santonin in crystals. In 1892 the reported annual production there was 70,000 pounds.

Properties. Santonin is in "colorless, shining, flattened, prismatic crystals, odorless and nearly tasteless when first put in the mouth, but afterwards developing a bitter taste; not altered by exposure to air, but turning yellow on exposure to light. Nearly insoluble in cold water; soluble in 40 parts of alcohol at 15° C. (59° F.), in 250 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in 140 parts of ether, in 4 parts of chloroform, and in solutions of caustic alkalies. When heated to 170° C. (338° F.), Santonin melts, and forms, if rapidly cooled, an amorphous mass which instantly crystallizes on coming in contact with a minute quantity of one of its solvents. At a higher temperature it sublimes, partly unchanged, and, when ignited, it is consumed, leaving no residue. Santonin is neutral to litmus paper moistened with alcohol.

Santonin yields, with an alcoholic solution of potassium hydrate, a bright pinkish-red liquid which gradually becomes colorless. From its solution in caustic alkalies, Santonin is completely precipitated by supersaturation with an acid. Its solution in cold, concentrated sulphuric acid is at first colorless (absence of *easily carbonizable, organic substances*), but after some time turns yellow, then red, and finally brown. If water be added, immediately after it is dissolved without color in sulphuric acid, it will be completely precipitated, and the supernatant liquid should not have a bitter taste, nor should it be altered upon the addition of potassium dichromate test-solution (absence of *brucine* or *strychnine*), or of mercuric potassium iodide test-solution (absence of *alkaloids in general*)." *U. S.* "Colorless flat rhombic prisms, feebly bitter, fusible and volatile when gently heated. Scarcely soluble in cold and sparingly in boiling *water;* soluble in 4 parts of *chloroform*, in 40 parts of cold and in 3 parts of boiling *alcohol* (90 per cent.). Sunlight renders it yellow. Added to warm *alcoholic solution of potassium hydroxide*, it yields a violet-red color. It is not dissolved by diluted mineral acids. Heated to redness, with free access of air, it burns without leaving any residue (absence of mineral impurity)." *Br.* For a new test for santonin, see *Pharm. Era*, 1898, 210. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to M. Sestini, the santonin is changed, through the influence of light, into formic acid, an uncrystallizable substance, much more soluble in alcohol and ether than santonin itself, which he calls *photosantonic acid*, $C_{15}H_{22}O_5$, and a red resinous substance. If the santonin be in alcoholic solution, after several months of exposure to sunlight it is changed into the ethyl ether of photosantonic acid. In its relations to polarized light it is very strongly lævogyrate, and retains this property with acids, though losing it entirely when combined with salifiable bases. (Buignet, *Journ. de Pharm.*, Janv. 1862, p. 26.) When warmed with alkalies, santonin is changed into monobasic *santoninic acid*, $C_{15}H_{20}O_4$, while concentrated baryta water changes it on prolonged boiling into the isomeric *santonic acid*. Schmidt (*Journ. de Pharm.*, 4e sér., iii. 394) disproved the previously accepted statement that santonin was a glucoside; but Hesse (*Deut. Chem. Ges. Ber.*, vi. 1280) found santonin to be the anhydride of *santoninic acid*, and prepared this acid by adding an excess of diluted hydrochloric acid to an aqueous solution of the sodium salt, and adding ether, from which the acid may be recovered by evaporation. When santonic acid is heated to 120° C. (248° F.), it is resolved into santonin and water. It has a strongly acid reaction, and decomposes sodium and calcium carbonate.*

Cannizzaro and Carnelutti (*Ber. d. Chem. Ges.*, xvi. 2685) have shown that santonic acid breaks up on high heating into *propionic acid*, $C_3H_6O_2$, and *dihydrodimethylnaphtol* $C_{10}H_7(CH_3)_2.OH$, and distilled over zinc dust it gives a mixture of dimethylnaphtol, $C_{10}H_5(CH_3)_2.OH$, dimethylnaphtalene, $C_{10}H_6(CH_3)_2$, and propylene.† *Santonone*, $(C_{15}H_{17}O_2)_2$,

* *Sodium santoninate* (*Sodii Santoninas*) was official in the *Pharmacopœia Germanica* of 1872, and was recognized in the U. S. P. of 1880. It may be prepared by adding santonin to a hot solution of caustic soda as long as it is dissolved; if the liquid is allowed to evaporate slowly, the crystals of sodium santoninate are obtained. It was officially described as in "colorless, transparent, tabular, rhombic crystals, slowly colored yellow by exposure to light, slightly efflorescent in dry air, odorless, having a mildly saline and somewhat bitter taste, and a slightly alkaline reaction. Soluble in 3 parts of water, and in 12 parts of alcohol at 15° C. (59° F.), in 0·5 part of boiling water, and in 3·4 parts of boiling alcohol. When heated to 100° C. (212° F.), until it ceases to lose weight, the salt loses 18 per cent. of its weight (water of crystallization). At a higher heat it chars and finally leaves an alkaline residue, which imparts an intense yellow color to a non-luminous flame. The aqueous solution, on the addition of hydrochloric acid, deposits a crystalline precipitate which is soluble in chloroform, and which yields, with alcoholic solution of potassa, a scarlet-red liquid gradually becoming colorless. A five-per-cent. aqueous solution of the salt should not be precipitated nor be rendered turbid by sodium carbonate test-solution (absence of *alkaline earths*), nor by picric or tannic acids (absence of *alkaloids*)." *U. S.* This salt was very properly dropped at the U. S. P. 1890 revision, because it is more easily absorbed than santonin in crystals, and therefore much more dangerous to the patient and much less destructive to *intestinal worms*. It must be remembered that serious poisoning from santonin has frequently occurred, notwithstanding its difficulty of absorption.

Santonin and Sodium Albuminate. Prof. Pavesi prepares this as follows: 1 part of santonin, 4 parts of sodium bicarbonate, and 2 parts of dried soluble albumen are warmed with a sufficient quantity of water at 60° to 70° F. until all are dissolved, and then evaporated to dryness at a very gentle heat. The santonin and sodium albuminate forms brilliant white scales, soluble in water. The mineral acids precipitate santonin and albumen, with disengagement of carbonic acid. The reasons for which Pavesi gives the preference to this combination over the use of santonin alone are the following. The after-effects of santonin, among others, that of yellowness of vision, are entirely obviated; the preparation is not decomposed in the stomach, because the sodium bicarbonate in the combination retains the santonin in solution, the coagulation of the albumen is prevented, gently purgative sodium salts are introduced into the body, and finally, by the disengagement of a small quantity of carbonic acid, an active digestion is produced. It is not at all probable that these assertions are correct, but more extended research is justifiable.

† The physiological and medical properties of various derivatives of santonin have been studied by F. Coppola and by Cannizzaro. Of the more important of these derivatives, *photosantonic* acid and *photosantonin* are said to be narcotics; whilst *isophotosantonin* and *isophotosantonic* acid are not hypnotics, but convulsants. It is asserted that *santoninoxime* is fully as efficacious as santonin as a germicide, but is much less poisonous to the higher animals than santonin, being absorbed and eliminated very slowly as santonin. It is insoluble in water, easily soluble in oils and

a decomposition product of santonin, is made by gradually adding zinc dust to a hot solution of santonin in acetic acid, preferably in the presence of a little platinum tetrachloride. It forms silky white needles, is very soluble in benzol, less so in hot alcohol, ether, or diluted acetic acid, and insoluble in water.

Medical Properties and Uses. Santonin has been used by oculists as a stimulant to the optic nerve in tobacco amaurosis and other forms of amaurosis; it is strongly commended in amenorrhœa by Dr. Bergy, but is chiefly used as a vermicide against the lumbricoid worm. In overdose it produces a poisoning whose symptoms are giddiness, mental apathy or stupor, great paleness and coldness of the surface, vomiting, profuse sweating, trembling, mydriasis, and finally loss of consciousness, with convulsions, often violent and accompanied by opisthotonos and emprosthotonos and failure of respiration. Xanthopsia is an early and characteristic symptom. All objects appear discolored, generally yellow, but frequently green, and sometimes blue. At the same time the urine is tinged of a yellow or a green color; and so rapidly does the santonin pass, that the change of color in the urine has been observed at the end of 16 minutes.* (*Journ. de Pharm.*, Août, 1863, p. 161.) These effects are probably due to the presence of santonin in the aqueous humor and the urine. In regard to the minimum fatal dose, two grains are said to have killed a feeble child five years old, and one six or seven years old is said to have been destroyed by six grains of the acid, after suffering from hæmaturia (*Bull. Thérap.*, lxxiv. 362); four grains produced very serious symptoms in a child four years old. (*P. J Tr.*, ix. 696.)

The santoninates are inferior to santonin, being more soluble; and for the same reason the principle is preferable in its natural crystalline form to the powder. Santonin is best administered in the form of lozenges made with sugar and tragacanth (for formula, see *A. J. P.*, vi. 124), which, if the unbroken crystals are used, can be rendered very pleasant to the taste, so that children will eat them as candy. The dose of santonin for an adult is from two to four grains (0·13–0·26 Gm.); for a child two years old, from one-fourth to one-half grain (0·016–0·03 Gm.). It has been affirmed that the white santonin is more poisonous than the yellow. (*A. J. P.*, 1887.)

SAPO. U. S. (Br.) Soap. [White Castile Soap.]

(SĀ'PŌ.)

"Soap prepared from soda and olive oil." *U. S.* "Soap made with sodium hydroxide and olive oil; containing about 30 per cent. of water." *Br.*

Sapo Durus, *Br.;* Hard Soap, Castile Soap; Savon, Savon blanc, Savon d'Espagne, *Fr.;* Oel-Sodaseife, Seife, Spanische Seife, *G.;* Sapone duro, *It.;* Jabon, *Sp.*

Soaps embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea*, consist generally of three principles, two solid, differing in fusibility, called *stearin* and *palmitin*, and one liquid, called *olein*, of which there are two varieties. Stearin is found most abundantly in fats which are firm and solid, as suet and tallow; and palmitin and olein in the oils. When the fats and oils undergo *saponification* by reaction with a salifiable base, these three principles are decomposed into oily acids peculiar to each, discovered by Chevreul, and called stearic, palmitic, and oleic acids, which unite with the base to form the soap, and into a sweet principle not saponifiable, called glycerin, which is set free. Hence it follows that stearin is a stearate of glyceryl, C_3H_5, the radical of the triatomic alcohol glycerin, $C_3H_5(OH)_3$, palmitin a palmitate, and olein an oleate, and that the fats and oils are mixtures of these three oily salts. Hence, also, it is obvious that soaps are mixed stearates, palmitates, and oleates of various bases. *Stearic acid*, $C_{18}H_{36}O_2$, is a firm white solid, like wax, fusible at 69·2° C. (157° F.), greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used as a substitute for wax in making wax candles. *Pal-*

fats, but not in organic acids, and is not acted upon by the gastric juice. P. Gucci prepares santoninoxime as follows. Boil a mixture of five parts of santonin, four parts of hydroxylamine hydrochlorate, fifty parts of alcohol, and three to four parts of calcium carbonate for six to seven hours on a water-bath, and add an excess of boiling water to the clear solution. The yield is 80 per cent. of the santonin employed. It crystallizes from alcohol in white, lustrous needles which melt at 216°–219° C., and dissolves readily in alcohol and ether, but very sparingly in boiling water. In hot solutions of alkaline hydrates and carbonates it dissolves, being precipitated unchanged on the addition of an acid. On being warmed with very dilute hydrochloric acid, the santonin is quantitatively reproduced. It is lævo-rotatory. It can be borne in two or three times larger doses than santonin. (*Gazz. Chim. Ital.*, xix. 367–382.)

* According to Dr. Walter G. Smith, the yellow color imparted to urine by santonin is distinguished from that produced by other substances by becoming purplish red on the addition of ammonia or other alkali. (*P. J. Tr.*, Dec. 1870, p. 528.) For researches upon the character of the urinary coloring matter, consult the same paper.

mitic acid, $C_{16}H_{32}O_2$, forms a white scaly mass, and melts at 62° C. (143·6° F.). *Oleic acid*, $C_{18}H_{34}O_2$, is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles, a little below 0° C. (32° F.), and having a slight smell and a pungent taste. (See *Acidum Oleicum.*) *Glycerin* is described under a separate head. (See *Glycerina.*)

Soaps are divided into the soluble and the insoluble. The soluble soaps are combinations of the fatty acids with soda, potassa, and ammonia; the insoluble consist of the same acids united with earths and metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is usually applied. Several of the insoluble soaps are employed in pharmacy; as, for example, the lead monoxide soap, or lead plaster, and the lime soap, or lime liniment. (See *Emplastrum Plumbi* and *Linimentum Calcis.*) The two official soaps are of the soluble kind. One is a soda soap, made with olive oil (Castile soap), the other a potassa soap (soft soap). (See *Sapo Mollis.*) The soap of ammonia is noticed elsewhere. (See *Linimentum Ammoniæ.*)

The consistency of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and palmitate they contain, and softer when the oleate predominates; and, as respects the alkali present, they are harder when formed with soda, and softer when containing potassa. Hence it is that of pure soaps, considered as salts, sodium stearate is the hardest and least soluble, and potassium oleate the softest and most soluble.

Preparation. The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, beginning with a weak solution, and as saponification proceeds using a stronger lye until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and the redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution until the excess of alkali forms a strong alkaline solution,which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface; and, when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap.* It may be purified by dissolving it in an alkaline lye and separating it by common salt. During this process the impurities subside, and the soap combines with more water; and hence it becomes weaker, although purer and whiter. If the grain soap be not purified, it will form *marbled soap*,—the colored streaks arising principally from an insoluble soap of oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of ferrous sulphate. The black ferrous oxide is precipitated, and gives rise to dark-colored streaks, which, by exposure to the air, become red in consequence of the conversion of the black oxide into the ferric oxide. When toilet soap is required, the *grained* soap, or, as it is sometimes called, *boiled* soap, is often remelted, perfumed, and worked over by the processes of *milling*, *plotting*, and *moulding*, whereby the soap is brought into the desired shape for popular use. The *cold process* is also used, and is preferred by many because of its simplicity and economy. The following (from Sadtler's *Industrial Organic Chemistry*, 1895, 62) gives the outlines of the process. The so-called "cold process" requires the use of exact weights of well-refined fats and of caustic soda of a given specific gravity (from 32°–36° B.), the quantities being such that only just enough soda is present to completely saponify the fat. The materials are allowed to stand together for a short time and then thoroughly mixed in a copper provided with steam agitating paddles, and kept at a temperature of not over 120° F. The reaction proceeds rapidly, and after some fifteen minutes the materials have so far united that they will not separate on standing, although the complete saponification of the charge may require days. They are then run out into the cooling frames. It is obvious that soaps made in this way retain all the glycerin originally combined with the fatty acids disseminated through the particles of soap, and belong to the class of "filled" or "padded" soaps. When cocoanut oil alone is used, the temperature of working in this cold process need not be higher than 75° F. in summer and 90° F. in winter; if one-half tallow, from 104° to 108° F., and if two-thirds tallow, from 113° to 120° F. is necessary. A well-refined tallow can be saponified in this way, too, and rosin may be added to it.*

* The following very practical process is by W. J. Menzies (*Chemist and Druggist*, Aug. 1880):

On the Manufacture of Soap in small Quantities without Boiling. Take exactly 10 lbs. of double-refined 98-per-cent. caustic-soda powder (Greenbank), put it in any can or jar with 45 lbs. (4½ gallons) of water, stir it once or twice, when

The official *soap* (Sapo, *U. S.;* Sapo Durus, *Br.*) is an olive oil soda soap, made on the same general plan as that just explained.

Common soap is also a soda soap; but instead of olive oil it contains solid animal fats. This soap corresponds with the white soap of northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it is manufactured from kelp and tallow. It was introduced into the U. S. Pharmacopœia of 1860 as the only proper soap for making opodeldoc; but, as this preparation was discarded, this variety of soap was dismissed along with it.

Besides the official soaps of the U. S. and Br. Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. The official soap of the French Codex (1837), called *amygdaline soap* (*almond oil soap*), is formed of caustic soda and almond oil, and is directed to be kept for two months exposed to the air before being used. *Starkey's soap*, also official in the Codex, is prepared by uniting, by trituration, equal parts of potassium carbonate, oil of turpentine, and Venice turpentine. *Beef's marrow soap* is a fine animal oil soap, also included in the French standard of pharmacy. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua luciæ*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with ammonia water. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. The soap is yellow or yellowish brown, and preserves its transparency after desiccation. The German transparent soap always contains a large quantity of cocoanut-oil soap. *Palm soap* is prepared from soda and palm oil, to which tallow is added to increase its firmness. If it be wanted white, the palm oil may be

it will dissolve immediately and become quite hot; let it stand until the lye thus made is cold. Weigh out, and place in any convenient vessel for mixing, exactly 75 lbs. of clean grease, tallow, or oil (*not* mineral oil). If grease or tallow be used, melt it slowly over the fire until it is liquid and *just warm*,—say temperature not over 37·7° C. (100° F.). If oil be used, no heating is required. Pour the lye slowly into the melted grease or oil in a small stream continuously, at the same time stirring with a flat wooden stirrer about three inches broad; continue gently stirring until the lye and grease are thoroughly combined and in appearance like honey. Do not stir too long, or the mixture will separate itself again. The time required varies somewhat with the weather and the kind of tallow, grease, or oil used: from 15 to 20 minutes will be enough. When the mixing is completed, pour off the liquid soap into any old square box for a mould sufficiently large to hold it, previously dampening the sides with water so as to prevent the soap sticking. Wrap up the box well with old blankets, or, better still, put it in a warm place until the next day, when the box will contain a block of 130 lbs. of soap, which can afterwards be cut up with a wire. Remember the chief points in the above directions, which must be exactly followed. The lye must be allowed to *cool*. If melted tallow or grease be used, it must not be more than *warm*. The *exact* weights of double-refined 98-per-cent. powdered caustic soda and tallow or oil must be taken; also the lye must be stirred into the grease, *not* the grease or oil added to the lye. If the grease or tallow used be not clean, or *contain salt*, it must be "rendered," or purified, previous to use, that is to say, boiled with water, and allowed to become hard again to throw out the impurities. Any salt present will spoil the whole operation entirely, but discolored or rancid grease or tallow is just as good as fresh for soap-making purposes.

If the soap turn out streaky and uneven, it has not been thoroughly mixed. If very sharp to the taste, too much soda has been taken. If soft, mild, and greasy, too little soda has been used. In either case it must now be thrown into a pan and brought to a boil with a little more water. In the first case boiling is all that is necessary; in the other instances a very little oil or a very little more of the double-refined powdered caustic soda must be added to the water. These things will never happen, however, if the directions be exactly followed, and after the soap has been made several times with the experience thus gained the process is extremely easy, and the result will be always a good soap. Beef tallow makes the hardest soap, mutton fat a rather softer soap; of oils, cotton-seed is the cheapest and best, but the soap is much softer, lathering very freely indeed. Ordinary household fat or drippings will make a nice soap, and in many places can be obtained at a very trifling cost and in exchange for goods sold. Such grease, however, must be carefully examined for *salt*, which it often contains. It will be evident that any smaller quantity of soap can be made at a time, according to the above directions, by taking the ingredients in exact proportion. It is not advisable to make more than double the quantity prescribed, as it is difficult to work more by hand. By making successive batches, however, a single person can make two tons of soap in a day simply with apparatus (pans, etc.) obtainable in any household.

By adding a few drops of essential oil just when the mixing is completed, a toilet soap is produced. Oil of mirbane (artificial almond oil) is the cheapest, but the perfume is not nearly so pleasant as real almond oil, citronella, or oil of cloves. If made with clean grease or tallow or light-colored oil, the soap produced is quite white.

Sometimes a little coloring matter will make soap *sell* better, although of no better quality. Half an ounce of potassium bichromate dissolved in the *lye* will give a green color; 1 lb. of palm oil melted with the tallow or oil, a yellow color; or a good brown can be got by burning ½ lb. of sugar in a saucepan until black, then dissolving it in a pint of water, and adding it to the melted tallow before mixing.

A *very cheap* and good jelly soft soap can be made with soap. Take 5 lbs. of the hard soap, crush it down or cut it up into as small pieces as possible; put this into a pan or boiler with 10 gallons of water if a strong hard tallow soap; if an oil soap, only half the quantity of water (5 gallons); just bring it to a boil, and stir well, to thoroughly dissolve all the pieces of hard soap; pour or ladle it into any can, tub, or barrel that is tight, and leave it to cool for two or three days. This will give about 80 lbs. of jelly soft soap at an exceedingly small cost. Of course, if made from colored and scented hard soap it will be a colored and scented jelly soap. This is a good way of working up the scraps and bits of soap after cutting up. It is a *very different* article, however, from a *real* potash soft soap, which should invariably be used for washing woollens. It is possible to produce this real potash soft soap in the cold by a process somewhat similar to the above.

bleached by heat, potassium bichromate with sulphuric acid, chlorine, or exposure to the sun. This soap has a yellowish color, and the agreeable odor of violets derived from the oil. *Soap balls* are prepared by dissolving soap in a little water and then forming it with starch into a mass of the proper consistence. *Common yellow soap* (*rosin soap*) derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed, the oil being added to improve its color. Sodium silicate has to some extent been substituted for resin, as more economical. (*A. J. P.*, 1863, p. 466.) Large quantities of lard oil (nearly pure olein) are manufactured into soap.*

All the varieties of soap, except a few of the fancy sort and the olive oil soaps, are manufactured in the United States. The latter are mainly imported from France, Italy, and Spain.

Properties. Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its smell is peculiar, and its taste slightly alkaline. It is usually somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and palmitates predominate. Acids added to an aqueous solution of soap combine with the alkali, and set free the oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold and abundantly in boiling alcohol. This solution constitutes the *tincture of soap*, and forms a very convenient test for discovering lime in natural waters. As the tincture sometimes gelatinizes, it is proposed by M. Bjorklund to remedy this inconvenience by employing soap in the nascent state, that is, containing a large proportion of water. (*Journ. de Pharm.*, 4e sér., ii. 179, 1865.) The efficacy of soap as a detergent depends upon its power of rendering grease and other soiling substances soluble in water and therefore capable of being removed by washing. The chief adulterations in soap are lime, silica, gypsum, heavy spar, steatite, pipe-clay, and sodium sulphate. When adulterated with these substances, it will not be entirely soluble in alcohol. According to Dr. Riegel, glue is an occasional adulteration in Spanish soap, discoverable also by its insolubility in alcohol. The same impurity is sometimes found in other soaps. Soap is officially described as "a white or whitish solid, hard, yet easily cut when fresh, having a faint, peculiar odor free from rancidity, a disagreeable, alkaline taste, and an alkaline reaction. Soluble in water and in alcohol, more readily with the aid of heat. On placing a small, weighed portion of Soap, together with about 10 C.c. of alcohol, in a tared beaker containing sand, evaporating the resulting solution of the Soap to dryness, and drying the residue at 110° C. (230° F.), the loss of weight should not exceed 36 per cent. (absence of an undue amount of *water*). A 4-per-cent. alcoholic solution of Soap should not gelatinize on cooling (absence of *animal fats*). An aqueous solution of Soap should remain unaffected on the addition of hydrogen sulphide or ammonium sulphide test-solution (absence of *metallic impurities*). On dissolving 20 Gm. of Soap in alcohol, with the aid of heat, transferring the undissolved residue, if any, to a filter, and washing it thoroughly with boiling alcohol, it should, after drying, weigh not more than 0·6 Gm. (limit of *sodium carbonate*, etc.); and at least 0·4 Gm. of this residue should be soluble in water (limit of *silica* and *other accidental impurities*). If a solution of 5 Gm. of Soap in 50 C.c. of water be mixed with 3 C.c. of oxalic acid decinormal volumetric solution, the subsequent addition of a few drops of phenolphtalein test-solution should produce no pink or red tint (limit of *alkalinity*)." *U. S.* "Grayish-white, dry, inodorous; becomes horny and pulverizable when kept in dry warm air. Easily moulded when heated. Soluble in *alcohol* (90 per cent.), especially on warming. Soluble in 20 parts of cold *water*, and in 1½ parts of hot *water*. It should not contain more alkaline hydroxide or carbonate than is allowed under 'Sapo Animalis.' It does not impart a greasy stain to white unglazed paper (absence of free oil). Incinerated it yields an ash which does not deliquesce (absence of potassium soap). It should lose about 30 per cent. of moisture when dried at 230° F. (110° C.)." *Br.*

Olive oil soda soap (Sapo), otherwise called *Castile* or *Spanish soap*, is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap*, when good, is of a pale grayish-white color, incapable of giving an oily stain to paper, devoid of

* Upon the supposition that the detergent properties of soap depend exclusively on the alkali it contains, and are consequently proportionate to the quantity of that ingredient, a mode of estimating the relative value of soaps has been suggested by R. Graeger, based on the molecular weight of the fatty constituent,—those soaps being the strongest of which the acid has the lowest combining number. (See *A. J. P.*, 1861, p. 355.)

rancid odor or strong alkaline qualities, and entirely soluble both in water and in alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about 21 per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap thus adulterated is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. The proportion of water may be ascertained by introducing the soap into a saturated solution of sodium chloride, and boiling; when the soap, nearly free from water, concretes into a solid mass. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about 14 per cent. of water. Having less water than the white Castile, it is a stronger and more economical soap, but at the same time is less pure. The impurity arises from the veins of marbling, consisting of ferruginous matters, as already explained, and from various substances added as make-weights. Soap made with animal fat, with the probable addition of sodium silicate, has been sold for Castile soap. The Italian brands of Castile soap which have been so largely used in past years are rapidly depreciating in quality; they are now chiefly made from cotton-seed oil and other substitutes for olive oil.

Animal oil soda soap (Sapo Vulgaris) is a hard soap, of a white color, inclining to yellow. It is made from tallow and caustic soda. This soap possesses the same general properties as the olive oil soda soap.

Composition. It has been already explained that soap consists of certain oily acids united with an alkali. As olive oil is a compound of olein with palmitin and small quantities of the ethers of other fatty acids, so the official "soap" is a mixed sodium oleate and palmitate. The former official "common soap" is principally a sodium stearate; and "soft soap," as defined in the Br. Pharmacopœia, is a mixed potassium palmitate and oleate. The following table, from Roscoe & Schorlemmer, gives an excellent view of the composition of commercial soap.

	Fatty Acids.	Potash, K_2O.	Soda, Na_2O.	Water.	Salt and other Admixtures.
Hard Soaps.					
Old Mottled Soap	81·25	1·77	8·55	8·43	. .
New Tallow Soap	61·0	. .	8·4	28·8	2·3
Marseilles Soap	67·0	. .	7·8	21·2	4·0
Palm-oil Soap, yellow	65·2	. .	9·8	19·9	1·1

Palm-oil Soap	49·6	. .	8·0	35·4	1·1
Soft Soaps.					
Common Soft Soap	42·8	9·1	. .	48·0	. .
London Soft Soap	45·0	8·5	. .	46·5	. .
Belgian Green Soap	36·7	7·0	. .	57·0	. .

Incompatibles. Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the oily acids of the soap; the earths unite with the oily acids, and separate the alkali; while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft, and fit for washing, by adding sufficient sodium or potassium carbonate to precipitate all the lime.

Medical Properties. Soap possesses the properties of a laxative, antacid, and antilithic. It is seldom given alone, but frequently in combination with rhubarb, the astringency of which it has a tendency to correct. Thus combined, it is often administered in *dyspepsia*, attended with *constipation* and *torpor of the liver*. As it is readily decomposed by the weakest acids, which combine with the alkali, it often proves useful in *acidity of the stomach*, and has been recommended as a remedy in the *uric acid diathesis;* but it possesses no power to dissolve calculi, as was once supposed. Externally, soap is a stimulating discutient, and as such has been used by friction in *sprains and bruises*. The late Dr. A. T. Thomson found much benefit to result from rubbing the tumid abdomen of children in *mesenteric fever*, morning and evening,

with a strong lather of soap. For the cure of *itch*, Dr. Schubert recommends a mixture of soft soap and salt, in the proportion of eight ounces of the former to four of the latter, dissolved in a quart of water. With this solution, previously warmed, the patient is to be rubbed, night and morning, until a cure is effected, which generally takes place in three days. M. Thénard recommends a solution of soap as an infallible remedy against the bedbug (Fr. *punaise*), which, as well as the egg, is destroyed by a hot solution made by boiling together one part of soap with fifty parts of water. (*Journ. de Pharm.*, 3e sér., xxviii. 280.) In *constipation* of the bowels, particularly when arising from hardened fæces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is also an ingredient in some liniments and plasters. In toxicology it is used as a counter-poison for the mineral acids, and should always be resorted to in poisoning by these agents, without a moment's delay, and its use continued until magnesia, chalk, or sodium or potassium bicarbonate can be obtained. The mode of administration, in these cases, is to give a teacupful of a solution of soap, made by dissolving it in four times its weight of water, every three or four minutes, until the patient has taken as much as he can swallow. The dose of soap is from five grains to half a drachm (0·33–1·95 Gm.), given in pill.

SAPO ANIMALIS. Br. Curd Soap.

(SĀ'PŌ ĂN-Ị-MĀ'LĬS.)

"Soap made with sodium hydroxide and a purified animal fat consisting principally of stearin; containing about 30 per cent. of water." *Br.*

Sapo domesticus; Savon animal, *Fr.*; Hausseife, *G.*

The British Pharmacopœia 1898 has retained curd soap in its list, and thus describes it: "White or with a very light grayish tint; dry; nearly inodorous; becomes horny and pulverizable when kept in dry warm air. Easily moulded when heated. Soluble in *alcohol* (90 per cent.), especially on warming. Sparingly soluble in cold *water;* soluble in hot *water*. 5 grammes of the dried and powdered soap, digested in boiling *alcohol* (90 per cent.), filtered while hot, and the filter washed thoroughly with more of the boiling *alcohol*, yield a filtrate which should not afford a red or pink coloration with *solution of phenol-phthalein* (limit of alkaline hydroxide); and the filter, when washed with hot water, will yield a solution which, on adding *solution of phenol-phthalein*, should not require more than 3 cubic centimetres of *decinormal volumetric solution of sulphuric acid* to discharge the resulting red color (limit of alkaline carbonate). It does not impart a greasy stain to white unglazed paper (absence of free oil and fat). Incinerated it yields an ash which does not deliquesce (absence of potassium soap). It should lose about 30 per cent. of moisture when dried at 230° F. (110° C.)."

Soap made from animal oils and fats is very largely used for all domestic purposes; it is preferred pharmaceutically for making *solid opodeldoc* because of its partial insolubility in the hydro-alcoholic solvent. (See p. 1194.)

SAPO MOLLIS. U. S., Br. Soft Soap. [Sapo Viridis, U. S. P. 1880. Green Soap.]

(SĀ'PŌ MŎL-LĬS.)

"Soap made with potassium hydroxide and olive oil." *Br.*

Savon mou, Savon vert, Savon à Base de Potasse, *Fr.*; Schmierseife, Kaliseife, *G.*

"Linseed Oil, *four hundred grammes* [or 14 ounces av., 48 grains]; Potassa, *ninety grammes* [or 3 ounces av., 76 grains]; Alcohol, *forty cubic centimeters* [or 1 fluidounce, 169 minims]; Water, *a sufficient quantity*. Heat the Linseed Oil in a deep, capacious vessel, on a water-bath or steam-bath, to a temperature of about 60° C. (140° F.). Dissolve the Potassa in *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Water, add the Alcohol, and then gradually add the mixture, constantly stirring, to the Oil, continuing the heat until a small portion of the mixture is found to be soluble in boiling Water without the separation of oily drops. Then allow the mixture to cool, and transfer it to suitable vessels. The Potassa used in this process should be of the full strength directed by the Pharmacopœia (90 per cent.). Potassa of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 8100 by the percentage of absolute Potassa (potassium hydrate) contained therein." *U. S.* The above process was introduced into the U. S. P. 1890 with the view of affording a soft soap for medicinal purposes which shall be of uniform strength. *Soft soap* is prepared on

the same general principles as hard soap, potash being employed as the alkali, and a fatty matter, rich in olein, as the oil. The French soft soap is made with the seed oils, such as rape-seed, hemp-seed, etc.; the Scotch and Irish, with fish oil and some tallow; and our own, with refuse fat and grease. A lye of wood-ashes is the form of potash usually employed. In forming this soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a potassa soap completely dissolved in the solution of its alkali, which is consequently present in excess. As made in this country, it is usually semi-fluid, slippery, capable of being poured from one vessel to another, and of a dirty brownish-yellow color and indefinitely varying strength. It is officially described as "a soft, unctuous mass, of a yellowish-brown or brownish-yellow color. Soluble in about 5 parts of hot water to a nearly clear liquid; also in 2 parts of hot alcohol without leaving more than 3 per cent. of insoluble residue." *U. S.* "Yellowish-white, sometimes yellowish-green, almost inodorous, of an unctuous consistence. Readily soluble in *alcohol* (90 per cent.), especially on warming, the liquid, on filtration, yielding not more than 3 per cent. of residue (limit of potassium carbonate, insoluble soaps, etc.). It should not contain more alkaline hydroxide or carbonate than is allowed under 'Sapo Animalis.' It does not impart an oily stain to paper (absence of free oil). Incinerated it yields an ash which is very deliquescent, and which should afford no reaction with the tests for copper." *Br.*

For more than one hundred years, under the name of "*green soap*," there has been used in Europe a soap made by saponifying linseed, rape-seed, or other vegetable oils with various refuse oils, usually including fish oils, an excess of potash, and a little soda. The green color of this soap was probably due to the presence of chlorophyll in the impure vegetable oils used. This green soap, or so-called "*German soap*," was formerly largely imported into America, but at present has been almost entirely superseded by soft soap made in this country, from which it does not differ in the nature of its active constituents or in its therapeutic properties.

If a green soap be wanted, it may be made by the process given in the foot-note.* The soft soap of France, the *savon vert* of the French Codex, has a greenish color and usually the consistence of a soft ointment. It is made of hemp-seed oil, or sometimes of the dregs of olive oil, and potash.

Medical Properties and Uses. Soft soap is used in medicine almost exclusively in the treatment of *eczema rubrum*, although sometimes used in other diseases of the skin in which a very powerfully stimulant detergent application is desired. It acts chiefly by virtue of the excess of potash, which enables it to destroy fatty matters rapidly, to remove exudation, and to affect the nutrition of the skin. The tincture, the form in which it is usually employed, may be well rubbed upon the part, either in full strength or diluted, and immediately afterwards the skin must be well washed to remove the alkali, and then zinc oxide or other bland ointment applied.

SARSAPARILLA. U. S. (Br.) Sarsaparilla.

(SĂR-SĄ-PĄ-RĬL'LĄ.)

"The root of Smilax officinalis, Kunth, Smilax medica, Chamisso et Schlechtendal, Smilax papyracea, Duhamel, and of other, undetermined species of Smilax (nat. ord. Liliaceæ)." *U. S.* "The dried root of Smilax ornata, Hook. f. Imported from Costa Rica and commonly known as Jamaica sarsaparilla." *Br.*

Sarsæ Radix, *Br.;* Jamaica Sarsaparilla; **Radix Sarsaparillæ,** *P. G.;* Salsepareille, *Fr.;* Sarsaparille, Sarsaparilla, *G.;* Salsapariglia, *It.;* Zarzaparilla, *Sp.*

In the present state of our knowledge, it is impossible to decide with positiveness from what species the several commercial varieties of the drug are respectively derived. This much is certain, that they do not proceed from the same plant. Of the many species belonging to this

* "*German Soft Soap.*" Mr. E. B. Shuttleworth has furnished the following process for its preparation. "In a clean pot or dish, preferably of iron or copper, and capable of containing at least three times the quantity, put one part by weight of linseed oil; heat gently, and add, in two portions, three parts in all, by measure, of liquor potassæ, U. S. P. or B. P., providing either come up to the standard requiring 5·8 and 5·84 per cent. of potassium hydrate. Boil quietly and stir frequently until the mass becomes clear, which with four ounces of oil and twelve ounces (fluid) of liquor will require about one hour, and with ten pounds of oil about five hours. If, during the process, the mass becomes too thick to stir easily, add a little water. Allow the soap to become cool, but, before it sets, work in the coloring matter, which must be previously prepared by boiling finely-powdered indigo with water until the color is formed into a thin paste. Twenty grains of indigo, boiled with one and a half ounces of water until the mixture is reduced to about one drachm, will answer for the soap from four ounces of oil. The soap must not be too hot, nor must it be reboiled after adding the coloring matter, or the green will be destroyed." (*Canad. Pharm. Journ.*, June, 1878.)

genus, few possess any medicinal power; and Hancock states that of the six or eight which he found growing in the woods of Guiana only one presented in any degree the sensible properties of the genuine sarsaparilla, the rest being insipid and inert. The root (rhizome) of *Smilax china*, a native of China and Japan, has been employed under the name of *China Root* for similar purposes with the official sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown color externally, whitish or of a light flesh-color internally, without odor, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of Smilax, is the product of *Hemidesmus indicus*.* (See *Hemidesmus*.) All the species of Smilax are climbing or trailing plants, with prickly stems,—a character expressed in the name of the medicine, which is derived from two Spanish words (*zarza parilla*), signifying a small thorny vine.

Humboldt, and much more recently Warszewicz, collected *S. officinalis*, with roots agreeing in all respects with the Jamaica sarsaparilla of commerce, on the Magdalena River in Colombia. The plant is said also to be cultivated in Jamaica. (Flückiger and Hanbury.) Schiede has proved that the Vera Cruz sarsaparilla is the root of *S. medica*. *S. syphilitica* has been claimed as a sarsaparilla plant.

S. officinalis. H. B. K. *Nov. Gen. et Sp.* (1815) 271. In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five- or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. Large quantities of the root are said to be sent down the Magdalena River to Mompox and Carthagena. It is supposed to yield the Jamaica sarsaparilla of commerce.

S. papyracea, Duham, *Arb.*, ed Nov. 1, 242, is said to have foliage like *S. officinalis*, with a multiangular stem, with squamiform thorns on the angles, and petioles which are vaginate for one-fourth their length. It is thought to be the source of Pará sarsaparilla.

S. medica. Schlecht. et Cham., in *Linnæa* (1831), 47. This species has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate, the upper cordate-ovate. In the old leaves the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle, and pedicels about three lines long.

The medicinal species of Smilax grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizome, from which the stems of the plant rise. The whole root with the rhizome is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The commercial sarsaparillas are conveniently divided into the mealy and non-mealy sarsaparillas. The first class comprises especially the Honduras, Guatemala, and Brazilian varieties; the second the Jamaica, Mexican, and Guayaquil sarsaparillas. A very convenient key for distinguishing the commercial sarsaparillas by certain anatomical characters has been devised by Luerssen in his *Handbuch der Medicin-pharm. Botanik*, ii. 404.

Honduras sarsaparilla (Fig. 1) is the variety most used in this country. Regarding the botanical origin of this drug little or nothing is definitely known. It is brought from the Bay of Honduras, and comes in bundles two or three feet long, composed of several roots folded lengthwise and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibres, either lying loose or still adhering to the roots. The roots externally are a dirty grayish or reddish brown; the cortical portion beneath the epidermis often appears amylaceous when broken.

The *Jamaica* or *red sarsaparilla* of foreign writers is little known by that name in the United States. The island of Jamaica is merely its channel of exportation to Europe; and it

* Under the name of *Raiz de china de México*, the Mexican Pharmacopœia recognizes the root of *S. rotundifolia* as diaphoretic and depurative, but, according to Prof. Maisch, this reference is incorrect. (See *A. J. P.*, 1879.)

is probably derived originally from Central America. It does not materially differ in properties from Honduras sarsaparilla, its chief peculiarity being the reddish color of the epidermis, which is also sometimes found in that variety. It is said also to yield a larger proportion of extract, and to contain less starch. As found in commerce it is in bundles from twelve to eighteen inches long by four or five in thickness, consisting of long slender roots folded up, with numerous radical fibres attached.*

The *Mexican* or *Vera Cruz sarsaparilla* (Fig. 3) comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. This variety was formerly little esteemed; but, from the acrid taste which it possesses, it is probably of equal value to the other kinds. It is probably derived from *Smilax medica.*

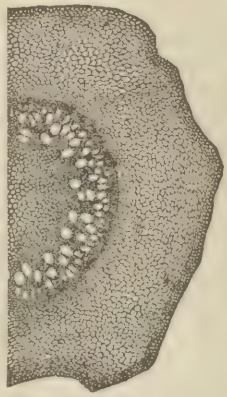

FIG. 1.—Honduras Sarsaparilla.

FIG. 2.—Rio Negro Sarsaparilla.

FIG. 3.—Mexican Sarsaparilla.

Another variety is the *Carácas sarsaparilla*, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, leaving much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and carefully. The radicles are often very amylaceous internally, in this respect resembling the following variety.

The *Brazilian* (Fig. 2), or, as it is called in Europe, the *Lisbon* or *Pará sarsaparilla*, is not very plentiful in commerce. It comes from the ports of Pará and Maranham, in cylindrical bundles from three to five feet in length by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizome) and stems, and having few radical fibres. It was also shown in the Brazilian exhibit in the Centennial Exhibition, neatly cut and tied into bundles about a foot long and eight inches in diameter. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *sarsa of the Rio Negro*, and is considered the most valuable variety of the drug. It is distinguished by the amylaceous character of its interior structure, and has considerable acrimony. It was said by Martius to be derived from *Smilax syphilitica;* but Dr. Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Pará, as the product of an undescribed species, certainly not *S. syphilitica.* According to Richard, it is the product of the *S. papyracea* of Poiret. (See *A. J. P.*, xv. 277.)

* A smilax is cultivated in Jamaica as a sarsaparilla, but probably yields little or none of the Jamaica sarsaparilla of commerce. Its roots are said to be of a light brown color, and more amylaceous than the commercial Jamaica sarsaparilla. The question as to the identity of the cultivated plant has been considerably discussed. In 1889 Sir Joseph Hooker, having, however, only male flowers grown in Kew Gardens, decided that it is not the *Smilax officinalis* H. B. K., but is probably identical with the *Smilax ornata* of Lemaire. (*Chem. and Drug.*, 1889.)

The variety described by Professor Bentley under the name of *Guatemala sarsaparilla* was collected in the province of Sacatapeques, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acrimony, and is probably one of the most efficient varieties. Professor Bentley ascribes it to *S. papyracea*. For a particular description of the root, see *P. J. Tr.*, xii. 472.

Guayaquil sarsaparilla, according to Mr. Spruce, grows in valleys on the western slopes of the equatorial Andes. It is usually not in bundles, but carelessly packed in bales. "The rhizome and a portion of the stem are often present, the latter being round and prickly. The root is dark, large, and coarse-looking, with a good deal of fibre. The bark is furrowed, rather thick, and not mealy in the slenderer portions of the root, which is near the rootstalk; but, as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting when cut a fawn-colored or pale yellow interior."

Properties. The dried sarsaparilla roots are several feet in length, about the thickness of a goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion, covered with a thin easily separable epidermis, of an inner layer of ligneous fibre, and of a central pith. The epidermis is of various colors, generally ash-colored, grayish brown, or reddish brown, and sometimes very dark. It is composed of several rows of elongated flattened cells, with their walls thickened by secondary deposits. The cortical portion is in some specimens whitish, in others brown, and not unfrequently of a pink or rosy hue. It is occasionally white, brittle, and almost powdery like starch. It is formed of a loose parenchymatous tissue, whose cells are often loaded with starch and raphides. Between it and the woody centre is a circle of small cells, which form the so-called nucleus sheath. The woody part is usually very thin, and composed of longitudinal fibres, which allow the root to be split with facility through its whole length. Its vascular bundles contain pitted ducts and prosenchymatous cells. Scattered vascular bundles sometimes occur in the central medulla, which is composed of large medullary cells. The cells of the endoderm are nearly square in transverse section, and uniformly thickened.

Sarsaparilla in its ordinary state is nearly or quite inodorous, but in decoction acquires a decided and peculiar smell. To the taste it is mucilaginous and very slightly bitter, and, when chewed for some time, produces a disagreeable acrid impression, which remains long in the mouth and fauces. "The thick, woody, knotty rhizome, if present, should be removed." *U. S.* The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion, while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes; and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water, cold or hot, but are impaired by long boiling. They are extracted also by diluted alcohol. According to Hancock, the whole of the active matter is not extracted by water. He observes in his paper upon sarsaparilla, published in the *London Medico-Botanical Transactions*, when speaking of the sarsaparilla from Pará and the Rio Negro, "After exhausting half a pound of this sort by two digestions, boiling, and pressure, I added to the dregs half a pint of proof spirit, and digested this with a gentle heat for a few hours in a close vessel; then, affusing hot water to the amount of that taken off from the first boiling, and pressing again, I procured by the last operation about four pints of an infusion which possessed the acrid properties of the sarsa in a much higher degree even than that obtained by the first decoction with simple water." It appears that in South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists. It has been suggested that sarsaparilla, the virtues of which are admitted to be impaired by long boiling, might also be injured by the degree of heat applied in the water- or steam-bath. But the contrary appears to have been proved by Prof. J. F. Judge, of Cincinnati. (*Proc. A. P. A.*, 1873, p. 595.)

Parillin. (*Smilacin. Pariglin. Salseparin. Parillinic acid.*) The crystalline principle in which the virtues of sarsaparilla reside is now called *parillin*. It was first discovered by Dr. Palotta, who described it in 1824 under the name of *pariglin*. Subsequently, M. Folchi

supposed that he had found another principle, which he called *smilacin*. Prof. Flückiger recommends the preparation of *parillin* by exhausting the crushed root with warm alcohol and distilling the tincture until the residue weighs one-sixth of the root. It is then gradually mixed with one and a half times its weight of water, and after several days the liquid is decanted from the light yellow precipitate, which is then mixed with about half its volume of alcohol, transferred to a filter, and washed with alcohol of 20 or 30 per cent. Parillin is less soluble in weak than in strong alcohol or in water. The yield was 0·18 and 0·19 per cent. It is white, inodorous, almost tasteless in the solid state, but bitter, acrid, and nauseous when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, without crystallizing on cooling. It is very soluble in alcohol, especially at the boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much on agitation. According to Flückiger, concentrated sulphuric acid yields a yellow solution, which, on absorbing moisture, gradually turns cherry-red; warm diluted sulphuric acid colors parillin greenish, then red, and finally brown; phosphoric acid has a similar reaction, but the color is more greenish-yellow. The aqueous solution is precipitated by alcoholic solution of lead acetate, by lead subacetate, and by tannin, and when warmed reduces alkaline copper tartrate, but does not react with other tests for sugar until after it has been boiled with a dilute acid, when the solution acquires a green fluorescence. This is best observed if a trace of parillin is dissolved in warm concentrated sulphuric acid, and disappears on dilution with water or on neutralizing with ammonia. Parillin is not sternutatory: its acrid taste is best observed in alcoholic solution. (See *A. J. P.*, xii. 245.) The solutions of parillin are without acid or alkaline reaction. By treatment with dilute mineral acids, it is resolved into *parigenin* and sugar. M. Poggiale found parillin both in the cortical and in the medullary part of the root, but most largely in the former. W. von Schulz (*P. J. Tr.*, 1892, 6) has shown that Dragendorff's *smilacin* or sarsaparill-saponin, $C_{20}H_{32}O_{10}$, *sarsa-saponin*, $C_{22}H_{36}O_{10}$, discovered by himself, and Flückiger's *parillin*, $C_{26}H_{44}O_{10}$, are three homologous compounds all belonging to the same series, having the general formula $C_nH_{2n-8}O_{10}$. These three all split up into *sarsa-sapogenin* (parigenin of Flückiger) and one or more molecules of glucose on boiling with dilute acids. Prof. Kobert (*A. J. P.*, 1892, 465) comes to practically the same results, stating the constituents to be *parillin* ($C_{26}H_{44}O_{10} + 2\frac{1}{2}H_2O$), insoluble in water; *saponin* (sarsaparill-saponin), $5(C_{20}H_{32}O_{10} + 2\frac{1}{2}H_2O)$, soluble in water; and *sarsa-saponin*, $12(C_{22}H_{36}O_{10} + 2H_2O)$, easily soluble in water, and the most poisonous of the constituents.

The sarsaparilla of commerce is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of Smilax. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert.

Medical Properties and Uses. Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal complaint, in which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed till about a century ago, when it was again brought into notice by Sir William Fordyce and others, as a useful adjuvant and corrigent of mercury in *lues venerea*. Since that period very different opinions have been entertained of it. Some, among whom was Dr. Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, among both regular practitioners and empirics, would seem to have placed its efficacy beyond reasonable doubt. Its most extensive and useful application is in the treatment of *secondary syphilis* and *syphiloid diseases* and that shattered state of the system which sometimes follows the imprudent use of *mercury* in these affections. It is also employed, though with less obvious benefit, in *chronic rheumatism*, *scrofulous affections*, certain *cutaneous diseases*, and other depraved conditions of health. Its mode of action is less evident than its ultimate effects. It is said to increase the perspiration and urine; but, allowing it to do so, the effect is too slight to explain its remedial influence; and even that which is produced has been ascribed by some to the medicines with which it is generally associated, or to the liquid in which it is exhibited. In this ignorance of its precise *modus operandi*, we call it an alterative.

Sarsaparilla may be administered in the form of infusion, decoction, syrup, or fluid extract.

A beer made by fermenting an infusion of the drug with molasses is said to be a popular remedy in South America.* The smoke of sarsaparilla has been highly recommended in asthma. (*Journ. de Pharm.*, xviii. 221.)

SASSAFRAS. U. S. (Br.) Sassafras.

(SĂS'SĄ-FRĂS.)

"The bark of the root of Sassafras variifolium (Salisbury), O. Kuntze (nat. ord. Laurineæ)." *U. S.* "The dried root of Sassafras officinale, T. Nees and Eberm." *Br.*

Sassafras Radix, *Br.;* Sassafras, *Fr., G.;* Sassafras, Sassafrasso, *It.;* Sasafras, *Sp.*

SASSAFRAS MEDULLA. U. S. Sassafras Pith.

(SĂS'SĄ-FRĂS MĘ-DŬL'LĄ.)

"The pith of Sassafras variifolium (Salisbury), O. Kuntze (nat. ord. Laurineæ)." *U. S.*

Laurus sassafras. Linn. *Sp. Pl.* 1753.—*Laurus variifolia*, Salisb. *Prodromus*, etc., 1796.—*Sassafras officinale.* Nees ab Esenbeck and Ebermaier (1830).—*Sassafras variifolia*, Salisb. O. Kuntze.†—*Sassafras sassafras.* Karsten, *Deutsch. Fl.* (1880–83). This is an indigenous tree, of middling size, rising in favorable situations from thirty to fifty feet, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little more than a shrub. The bark of the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side; but the greater number are three-lobed. Their mean length is four or five inches. The flowers, which appear before the leaves, are small, of a pale greenish-yellow color, and disposed in racemes which arise from the branches below the leaves and have linear bracts at their base. The corolla is divided into six oblong segments. The male flowers have nine stamens; the hermaphrodite, which are on a different plant, have only six, with a simple style. The fruit is an oval drupe, about as large as a pea, of a deep blue color when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception. For the microscopical character of the root and bark, see E. S. Bastin, *A. J. P.*, June, 1895.

The sassafras is common throughout the United States, and extends into Mexico. The fresh flowers have a slightly fragrant odor, and almost all parts of the plant are more or less aromatic. The best time for collecting the pith is after the occurrence of frost in autumn; and the same is the case also with the bark of the root. The wood of the root is brownish white, the bark spongy and divisible into layers. Although the Br. Ph. recognizes the whole root as official, the activity resides in the bark, which alone should be employed.

1. *Sassafras Pith.* This is in slender cylindrical pieces, very light and spongy, with a mucilaginous taste, and in a slight degree the characteristic flavor of the sassafras. It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which, though ropy and viscid, has much less tenacity than that of gum arabic and will not answer as a substitute in the suspension of insoluble substances. It differs also from solutions of ordinary gum, in remaining limpid when added to alcohol. This mucilage is much employed as a soothing application in inflammation of the eyes, and forms an agreeable and useful drink in dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

2. *Bark of Sassafras Root.* As found in commerce, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter color than that of the exposed surfaces. The living bark is nearly white, but becomes colored, on exposure, immediately after collection. Its odor is highly fragrant, its taste sweetish and gratefully aromatic. These properties are extracted by water and alcohol. According to Dr.

* The following is a formula recommended by Hancock. "Take of Rio Negro sarsa, bruised, 2 pounds: bark of guaiac, powdered, 8 ounces; raspings of guaiac wood, anise-seeds, and liquorice root, each 4 ounces; mezereon, *bark of the root*, 2 ounces; treacle [molasses], 2 pounds; and a dozen bruised cloves; pour upon these ingredients about four gallons of boiling water, and shake the vessel thrice a day. When fermentation has well begun, it is fit for use, and may be taken in the dose of a small tumblerful twice or thrice a day." This formula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, might be omitted, or replaced by the wood.

† It is unfortunate that the Pharmacopœia should have adopted a name which is not recognized by either Sargent; in his *Sylva*, or Britton and Brown or Engler and Prantl. The latter authorities recognize *S. officinale*, Nees, whereas the others hold to *Sassafras sassafras* (L.), Karst.

Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar decomposition product of tannic acid called *sassafrid*, tannic acid, gum, albumen, starch, lignin, and salts. The sassafrid bears some analogy to cinchonic red, and, like it, appears to be a derivative of the tannin, which exists in much larger proportion in the fresh bark than in that long kept. (Procter, *A. J. P.*, 1866, p. 490.) Owing to its volatile oil and tannic acid, the bark of sassafras root is an aromatic stimulant and astringent. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavor of which it improves, while it renders them more cordial to the stomach. The volatile oil may be used as an aromatic. In overdoses it is capable of producing marked narcotic poisoning, and it is said to act upon the lower animals as a narcotic. Dr. John Bartlett has reported several cases in which its use apparently caused abortion.

SCAMMONIÆ RADIX. Br. Scammony Root.

(SCAM-MŌ′NI-Æ RĀ′DĬX.)

"The dried Root of Convolvulus Scammonia, Linn." *Br.*

The root of the Scammony is recognized by the British Pharmacopœia solely for the preparation of the resin. It is officially described as "Brownish-gray or yellowish-gray, tapering or nearly cylindrical roots, varying usually from one to three inches (two and a half to seven and a half centimetres) or more in diameter. The Root is frequently contorted and the surface longitudinally furrowed. It is enlarged at the crown, and bears the remains of slender aerial stems. The fracture is very coarsely fibrous; internally the color is light or dark gray. The section exhibits an abnormal wood, consisting of numerous irregularly arranged wood bundles; and, when examined under the microscope, appears beset with starch grains of characteristic shape, and, especially in the cortical region, with resin-cells. Odor characteristic; taste at first somewhat sweet, afterwards slightly acrid. It yields to *alcohol* (90 per cent.) a resin which should have the properties of Scammony Resin." *Br.* The wood consists of compressed pale brown, coarsely porous, usually subdivided, fibres in a parenchymatous tissue similar to the bark. For microscopic structure, see *Dragendorff's Jahresbericht*, 1875.

SCAMMONIUM. U. S., Br. Scammony.

(SCAM-MŌ′NI-ŬM.)

"A resinous exudation from the living root of Convolvulus Scammonia, Linné (nat. ord. Convolvulaceæ)." *U. S.* "A gum-resin obtained by incision from the living root of Convolvulus Scammonia, Linn. Known in commerce as virgin scammony." *Br.*

Scammonée, *Fr.;* Scammonium, *G.;* Scamonea, *It.;* Escamonea, *Sp.*

Convolvulus scammonia. L. *Sp. Pl.* (1753) 55; Willd. *Sp. Plant.* i. 845; *B. & T.* 187. This vine has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes fifteen or twenty feet upon the ground or on neighboring plants, and furnished with smooth, bright green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together, upon the peduncles, which are round, axillary, solitary, and of nearly twice the length of the leaf. The plant is a native of Syria, Anatolia, and the Archipelago.

Scammony is collected, according to Russell, in the following manner. In the month of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells, or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, chalk, ashes, fine sand, etc.; and it has been supposed that scammony sometimes consists wholly or in great part of the expressed juice of the root, evaporated to dryness by exposure to the sun or by artificial heat. According to Landerer, the roots from which the juice has been collected are in some places boiled with water in copper vessels, and the extract added to the juice, not so much with the purpose of adulteration as under the impression that it favorably modifies the action of the drug. Scammony is exported chiefly from Smyrna, though small quantities are said to be sent out of the country at Alexandretta, the sea-port of Aleppo. Dr. Pereira was

informed by a merchant who resided in Smyrna that it is brought in a soft state into that city upon camels, and afterwards adulterated by individuals called scammony-makers. The adulteration appears to be conducted in conformity with a certain understood scale, more or less foreign matter being added according to the price. The materials employed are chiefly chalk and some kind of flour or meal. Very little comparatively is exported perfectly pure. We obtain scammony either directly from Smyrna, or indirectly through some of the Mediterranean ports.*

The name of *Aleppo scammony* was formerly given to the better kinds of the drug, and of *Smyrna scammony* to those of inferior quality,—the distinction having probably originated in some difference in the character of the scammony obtained at these two places. But no such difference now exists, as scammony is brought from Smyrna of every degree of purity. It has been customary, in this country, to designate the genuine drug, of whatever quality, as Aleppo scammony, while the name of Smyrna scammony has been given to a spurious article manufactured in the south of France, and to other factitious substitutes. It is quite time that these terms should be altogether abandoned. We shall treat of the drug under the heads of genuine and factitious scammony.

Genuine Scammony. This is sent into commerce in drums or boxes, and is either in irregular lumps, in large solid masses of the shape of the containing vessel, into which it appears to have been introduced while yet soft, or in circular, flattish or plano-convex cakes. It seldom reaches us in an unmixed state. Formerly small portions of pure scammony were occasionally to be met with in Europe, contained in the shells in which the juice was collected and dried. This variety, denominated *scammony in shells*, is now scarcely to be found. The pure drug is called *virgin scammony*. It is in irregular pieces, often covered with a whitish-gray powder, friable and easily broken into small fragments between the fingers, with a shining grayish-green fracture soon passing into greenish black, and exhibiting under the microscope minute air-cells and numerous gray semi-transparent splinters.† It is easily pulverized, affording a pale ash-gray powder. When rubbed with water it readily forms a milky emulsion. It has a rather strong, peculiar odor, comparable to that of old cheese. The taste is feeble at first, and afterwards somewhat acrid, but without bitterness. It gives no evidence, when the requisite tests

* An interesting account of the collection and preparation of scammony in Anatolia, in the vicinity of Smyrna, has been communicated by Mr. S. H. Maltass to the *London Pharmaceutical Journ. and Trans.* (xiii. 264). The juice is collected in the same manner as described by Russell in reference to Syria. The product, however, of each plant is somewhat less. In some districts, according to Maltass, ten plants produce only a drachm of scammony; in others the average from each root is a drachm; and in a good soil a plant four years old will yield two drachms. The juice received in the shells is mixed with another portion scraped from the cut surface of the root; and this mixture is the pure or *lachryma scammony*. Only a small quantity of this is taken to Smyrna, the greater part being adulterated by the peasants before it reaches the markets. Sometimes the juice is worked up with a decoction of the roots, in which case it is black, heavier than the preceding, and not so easily broken. Sometimes they add a calcareous earth, in a proportion varying from 10 to 150 per cent. The kind thus prepared is usually kept for some time in Smyrna, and is apt to ferment, so as to become porous and lose its gloss. It is in irregular lumps, and is the kind usually sold in London as *lachryma scammony*. Another kind sold in London in rough lumps, and probably under the same name, is prepared in the interior of the country by mixing the juice with wheat starch, ashes, earthy matters, gum arabic or tragacanth, and sometimes wax, yolk of egg, pounded scammony roots and leaves, flour, or resin. A kind much used in Great Britain is prepared by the Jews in Smyrna, and is in the form of cakes as described in the text. It is of two qualities. The *first quality* is prepared by mixing *skilip* (which is an inferior kind of scammony prepared at Angora, and consists of from 30 to 40 per cent. of juice and 60 to 70 of starch) with 60 per cent. of inferior scammony from the neighborhood of Smyrna: the *second quality*, by mixing *skilip* with about 30 per cent. of the latter kind, and adding about 10 per cent. of gum arabic and black-lead. The first quality contains about 50 per cent. of resin, the second about 30 per cent. For an account of specimens of scammony sent by Mr. Maltass from Smyrna, see a paper by Mr. D. Hanbury in *P. J. Tr.* (xiii. 268).

Prof. Ch. Boulier, of Algiers, gives the following account of the collection of scammony in the northwestern parts of Anatolia. The plant is not cultivated, but grows wild in rocky places covered with brushwood. At the flowering period, about the end of June and beginning of July, the peasants go forth in search of localities among the mountains where it is most abundant, and, having satisfied themselves on this point, return home, provide themselves with the requisite implements, and set out for the place of collection. Clearing away the brushwood and stems, the peasant digs deeply around the root, then cuts off the top obliquely, and affixes a mussel-shell to the root so as to receive the juice as it flows from the dependent part. He then passes on to other plants, upon which he operates in like manner. After a time he retraces his steps, and empties the shells successively into a tinned copper vessel. Next day he goes over the same ground, and scrapes with a knife from the cut surface the juice which has in the mean time flowed out and partly concreted. This he mixes with that previously collected, and, when his vessel is full, takes it to some neighboring market, where it is bought up and sent to the wholesale druggists at Constantinople and Smyrna. The juice reaches the market in a pasty state, and whitish like cheese, except where exposed to the air. It is in these centres of trade, or on its way from the collectors, that the drug undergoes the various sophistications to which it is subjected,—the peasant himself being usually honest and not disposed to adulterate. (*Ibid.*, April, 1860, p. 521.)

† According to Maltass, the purest scammony has a reddish-black fracture, unless it has been mixed with water in its preparation, in which case it is black and very glossy. (*P. J. Tr.*, xiii. 266.)

are applied, of the presence of starch or calcium carbonate, leaves but a slight residue when burned, and yields about 80 per cent. of its weight to ether. Considerable quantities of what is called virgin scammony have been imported into this country since the drug-law went into operation; but, though some specimens are tolerably pure, the drug, on the whole, falls far short of the proper standard. Dr. E. R. Squibb examined many specimens, and found the proportion of resin to vary from 25 to 79·7 per cent.; only two or three, out of more than 30 examined, approaching the latter degree of purity within 10 per cent. (*A. J. P.*, Jan. 1863.)*

The official description and tests for scammony are as follows. "In irregular, angular pieces or circular cakes, greenish-gray or blackish, internally porous, and breaking with an angular fracture, of a resinous lustre; odor peculiar, somewhat cheese-like; taste slightly acrid; powder gray or greenish-gray. When triturated with water, Scammony yields a greenish emulsion; it does not effervesce on the addition of diluted hydrochloric acid, and the decoction, when cold, does not assume a blue color on the addition of iodine test-solution (absence of *starch*). Ether dissolves at least 75 per cent. of it; and, when the ether has been evaporated, the residue, dissolved in hot solution of potassium hydrate, is not reprecipitated by diluted sulphuric acid." *U. S.* "It should afford only the slightest reactions with the tests for starch, and should yield at least 70 per cent. of resin soluble in *ether*, and not more than 3 per cent. of ash on incineration. An alcoholic solution should not afford a blue color with *test-solution of ferric chloride* (absence of guaiacum resin)." *Br.*

The form of scammony chiefly found in our markets is that in circular cakes. These are sometimes flattish on both sides, but generally somewhat convex on one side and flat on the other, as if dried in a saucer or other shallow vessel. They are from four to six inches in diameter, and from half an inch to an inch and a half or even two inches thick in the centre, and are often found in fragments. They are hard and heavy, with a faintly shining roughish fracture, and when broken exhibit in general a structure very finely porous, sometimes almost compact, and in a very few instances cavernous. Their color externally is a dark ash or dark olive or slate color approaching to black; internally somewhat lighter and grayish, with an occasional tinge of green or yellow, but deepening by exposure. The small fragments are sometimes slightly translucent at the edges. The mass, though hard, is pulverizable without great difficulty, and affords a light-gray powder. It imparts to water with which it is triturated a greenish milky appearance. The smell is rather disagreeable, and similar to that of the pure drug. The taste, very slight at first, becomes feebly bitterish and acrid. This kind of scammony is never quite pure, and much of it is considerably adulterated. In some of the cakes calcium carbonate is the chief impurity; in others the adulterating substance is probably meal, as evidences of the presence of starch and lignin are afforded; and in others, again, both these substances are found. Christison discovered in the chalky specimens from 15 to 38 per cent. of calcium carbonate; in the amylaceous, from 13 to 42 per cent. of impurity. It was probably to the flat, dark-colored, compact, difficultly pulverizable, and more impure cakes that the name of *Smyrna scammony* was formerly given. These have been erroneously ascribed by some to *Periploca secamone*, a plant growing in Egypt.

Scammony is ranked among the gum-resins. It is partially dissolved by water, much more largely by alcohol and ether, and almost entirely, when pure, by boiling diluted alcohol. Its active ingredient is resin, which constitutes from 80 to 90 per cent. of pure dry scammony. (See *Resina Scammonii.*) The gum-resin has been analyzed by various chemists, with varying results, as the character of the specimens examined is insufficiently determined by the terms Aleppo and Smyrna scammony employed to designate them. The resin is now known to be identical with that found in the root of the Mexican *Ipomœa orizabensis*, known in commerce as male jalap; and the name *jalapin* is given to it. (See *Jalapa.*) Bouillon-Lagrange and Vogel obtained from 100 parts of Aleppo scammony 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of Smyrna scammony, 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances. It is obvious that both the specimens upon which they operated were very impure. Marquart found in pure scammony (*scammony in shells*) 81·25 per cent. of resin, 3·00 of gum with salts, 0·75 of

* Dr. Squibb gives the following description of the drug imported as *virgin scammony*. "It generally occurs in solid square tin boxes, containing 25 to 28 pounds each. Occasionally, however, it is in round wooden boxes or drums of a similar capacity. The scammony is in irregular, rough and fissured masses of various sizes, sometimes porous, but commonly solid, hard, and semi-resinous, having a tough, dull fracture. It is of a very dark grayish-green color internally, often nearly black, but more of an ash color externally. It is rarely dry enough to be pulverulent, yet still more rarely too moist to be rubbed into coarse powder, and it generally loses 6 per cent. in drying sufficiently to make a fine powder." (*A. J. P.*, Jan. 1863, p. 49.)

wax, 4·50 of extractive, 1·75 of starchy envelopes, bassorin, and gluten, 1·50 of albumen and lignin, 3·75 of ferruginous alumina, chalk, and magnesium carbonate, and 3·50 of sand. Christison found different specimens of pure scammony to contain, in 100 parts, from 77 to 83 parts of resin, from 6 to 8 of gum, from 3·2 to 5 of lignin and sand, and from 7·2 to 12·6 of water, with occasionally a little starch, probably derived accidentally from the root, and not in sufficient quantity to cause a cold decoction of the gum-resin to give a blue color with iodine. Mr. Hanbury, of London, found 91·1 per cent. of resin in the purest scammony in shells. As already stated, scammony is seldom quite pure as found in commerce. Much of it contains not more than 50 per cent. of the resin, some not more than 42 per cent., and the worst varieties as little as 10 per cent., or even less. Sometimes the cakes are of good quality on the outside, and inferior within. In view of this uncertainty as to the strength of scammony, it is undoubtedly best to abandon its internal use altogether, employing only the resin, which is of uniform strength. Indeed, the resin has been officially substituted for the gum-resin in the compound extract of colocynth.

Factitious Scammony. Montpellier Scammony. Much spurious scammony is manufactured in the south of France, said by Guibourt to be made from the expressed juice of *Cynanchum monspeliacum*, incorporated with various resins and other purgative substances. M. Thorel, however, a pharmaceutist of Avallon, denies that this plant is employed in its preparation. (*Journ. de Pharm.*, xx. 107.) It has been occasionally imported into the United States and sold as Smyrna scammony. It is usually in flat semicircular cakes, four or five inches in diameter and six or eight lines thick, blackish both externally and within, very hard, compact, rather heavy, of a somewhat shining and resinous fracture, a feeble balsamic odor wholly different from that of genuine scammony, and a very bitter nauseous taste. When rubbed with the moistened finger it becomes dark gray, unctuous, and tenacious. We have seen another substance sold as Smyrna scammony, which was obviously spurious, consisting of blackish, circular, flat cakes, or fragments of such cakes, rather more than half an inch thick, very light, penetrated with small holes, as if worm-eaten, and when broken exhibiting an irregular, cellular, spongy texture. Dr. Pereira described a factitious substance sold as *Smyrna scammony*, which was in circular flat cakes about half an inch thick, blackish, and of a slaty aspect, breaking with difficulty, of a dull black fracture, and of the sp. gr. 1·412. Moistened and rubbed, it had the smell of guaiac; the adulteration was also detected by chemical tests.

Medical Properties and Uses. Scammony is an energetic cathartic, apt to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who not only gave it as a purgative, but also applied it externally for the cure of various cutaneous diseases. On account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated.* It should be given in emulsion with mucilage, sugar, almonds, liquorice, or other demulcent; and its disposition to gripe may be counteracted by the addition of an aromatic. The dose is from five to fifteen grains (0·33–1 Gm.) of pure scammony, from ten to thirty (0·65–1·95 Gm.) of that commonly found in the market.

SCILLA. U. S., Br. Squill.

(SQĬL'LĄ—sĭl'lą.)

"The bulb of Urginea maritima (Linné), Baker (nat. ord. Liliaceæ), deprived of its dry, membranaceous outer scales, and cut into thin slices, the central portions being rejected." *U. S.* "The bulb of Urginea Scilla, Steinheil, divested of its dry membranous outer scales, cut into slices, and dried." *Br.*

Bulbus Scillæ, *P. G.;* Squills; Squille, Scille, *Fr.;* Meerzwiebel, *G.;* Scilla, *It.;* Cebolla albarrana, *Sp.*

Urginea maritima (L.). Baker, *Journ. Linn. Soc.* (1873) 221.—*Urginea scilla.* Steinheil. *Ann. Sci. Nat.* (1834) 330.—*Scilla maritima.* L. *Sp. Pl.* (1753) 308; Willd. *Sp. Plant.* ii. 125. This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one

* *Triplex Pills.* Dr. J. W. Francis, of New York City, employed a combination of purgatives which afterwards became very well known as triplex pills. The original formula, obtained through Dr. E. R. Squibb, is as follows. Powdered Scammony, Powdered Socotrine Aloes, Blue Mass, of each, 1 *troyounce;* Croton Oil, 20 *minims;* Oil of Caraway, 1½ *fluidrachms;* Tincture of Aloes and Myrrh, 2 *fluidrachms.* Mix well, and make into 400 pills. The usual aperient or laxative dose is one pill at bedtime until the natural condition is restored. (*Proc. A. P. A.*, 1872.)

to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf. The squill grows on the sea-coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the official portion. It is generally dried for use, but is sometimes imported in the recent state packed in sand.

Properties. The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and the *white squill*. In the former the exterior coating is of a deep reddish-brown color, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscidity of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Dried squill, as found in commerce, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white color with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but often flexible from the presence of moisture, for which it has a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at the base. The odor is very feeble, the taste bitter, nauseous, and acrid.

The virtues of squill are extracted by water, alcohol, and vinegar. It has been analyzed by Vogel, M. J. H. Marais, Lebourdais, Tilloy, Merck, and lastly by Schmiedeberg (*Zeit. Physiol. Chem.*, 111, 112) with varying results. The bitter principle, not yet obtained pure, is *scillitin*. Merck, however, obtains three compounds of this class,—*scillipikrin*, *scillitoxin*, and *scillin*. Jarmersted (*Arch. f. Exper. Path.*, 11, 22) obtained a glucoside which he called *scillain*, but which seems to be identical with scillitoxin. Schmiedeberg (*loc. cit.*) found a peculiar mucilage, analogous to dextrin, which he calls *sinistrin*, $(C_6H_{10}O_5)_n$. It is white, easily soluble in water, insoluble in alcohol, lævo-rotatory; on boiling with dilute sulphuric acid it yields levulose and an inactive sugar of reducing properties. The mucilage is not affected by saliva or diastase. This last statement, however, is contradicted by F. Kurtz (*A. J. P.*, 1894, 246), who says that diastase acts upon it, producing a reducing sugar. Kurtz (*loc. cit.*) also obtained a reducing sugar (probably dextrose) along with the gum direct by extracting the bulb with hot alcohol. S. Wanizewski (*A. J. P.*, 1893, 498) finds *scillinine*, soluble in alcohol, but insoluble in water and in chloroform; *scillapicrine*, soluble in both water and alcohol; and *scillamarine*, soluble in both chloroform and alcohol. The bulbs of *Scilla maritima* also yield a slightly colored liquid oil of unpleasant odor when distilled in a current of steam. (*Husemann's Pflanzenstoffe*, 2d ed., p. 406.) Examined by the microscope, the bulb is seen to be pervaded by innumerable minute acicular crystals, consisting of inorganic salts, chiefly, according to M. Marais, calcium carbonate, with a little calcium chloride. (*Ibid.*) According to Hartwich, the mucilage occurs either in the form of large drops, filling the parenchymatous cells, or as masses enclosing the raphides. For an elaborate microscopic study, with plates, see *Arch. d. Pharm.*, July, 1889. Water distilled from it had neither taste nor smell, and was drunk by Vogel to the amount of six ounces without effect. When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

Medical Properties and Uses. Squill is expectorant, diuretic, and in large doses emetic and purgative. In overdoses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine; and it has retained to the present period a deserved popularity. As an expectorant, it is used in cases both of deficient and of superabundant secretion from the bronchial mucous membrane,—in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances it operates by stimulating the vessels of the lungs; and it should not be used when there is a high grade of inflammation, with arrested secretion. In *dropsy* it is much employed, especially in connection with digitalis, but, as it is distinctly irritant to the kidneys, it should not be used when there

is irritation or active inflammation of those organs. On account of its great uncertainty and occasional harshness, it is very seldom prescribed as an emetic, except in *croup*, in which it is usually given in the form of syrup. When given in substance it is most conveniently administered in the form of pill. The dose, as a diuretic or an expectorant, is one or two grains (0·065 or 0·13 Gm.) repeated two or three times a day, and gradually increased till it produces slight nausea or evinces its action upon the kidneys or lungs. From six to twelve grains (0·4–0·8 Gm.) will generally vomit. The vinegar and syrup of squill are official, and are much used. An *acetic extract* has been prepared by Mr. F. D. Niblett, by digesting a pound of squill with three fluidounces of acetic acid and a pint of distilled water, with a gentle heat, for forty-eight hours, then expressing, and, without filtration, evaporating to a proper consistence. One grain is equal to about three grains of the powder. (*P. J. Tr.*, xii. 133.)

SCOPARIUS. U. S. (Br.) Broom.

(SCŌ-PĀ'RĮ-ŬS.)

"The tops of Cytisus Scoparius (Linné), Link (nat. ord. Leguminosæ)." *U. S.* "The fresh and the dried tops of Cytisus Scoparius, Link." *Br.*

Scoparii Cacumina, *Br.;* Broom Tops; Herba Scoparii; Genêt à balais, *Fr.;* Gemeine Besenginster, Besenginster, Pfriemenkraut, *G.;* Scoparia, *It.;* Retama, *Sp.*

Cytisus scoparius (L.). Link, *Enum. Hort. Berol.* (1822) 241.—*Spartium scoparium.* L. *Sp. Pl.* (1753) 709.—*Sarothamnus scoparius.* Wimm., Koch, *Syn. Fl. Germ. et Helv.* (1837) 152. This is a common European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright green, very flexible branches, and small, oblong, downy leaves, usually ternate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow color, and solitary upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures.

The whole plant has a bitter, nauseous taste, and, when bruised, a strong, peculiar odor. The tops of the branches are the official portion. They are "in thin, flexible, branched twigs, pentangular, winged, dark green, nearly smooth, tough, usually free from leaves; odor peculiar when bruised; taste disagreeably bitter." *U. S.* The leaves, when present, are small, sessile, and simple above, stalked and trifoliate below. The seeds are said to be used sometimes, and to be as active as the tops. Water and alcohol extract their active properties. According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow coloring matter, tannin, a sweet substance, mucilage, albumen, and lignin. Dr. Stenhouse has separated from them two principles, *scoparin*, $C_{21}H_{22}O_{10}$,* and an alkaloid, *sparteine*, $C_{15}H_{26}N_2$. The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It is slightly soluble only in cold water, more readily in hot water with greenish light yellow color, easily soluble in aqueous ammonia and caustic and carbonated alkalies. It is decomposed by heat. When fused with caustic potash it yields, according to Hlasiwetz, phloroglucin and protocatechuic acid. Sparteine was obtained by distillation from the mother-waters of the scoparin. It is a colorless liquid, having a peculiar bitter taste, and all the properties of a volatile alkaloid. It is heavier than water, and boils at 288° C. if distilled in a current of hydrogen gas. It dissolves only slightly in water, but takes up some water itself. In contact with water it becomes opalescent. It turns yellowish on distillation in air, but can be distilled colorless in an atmosphere of carbon dioxide. It is colorless, but becomes brown by exposure to light; it has at first an odor of aniline, but this is altered by rectification. It readily neutralizes acids and forms crystallizable salts, which are extremely bitter. Its sulphate occurs in colorless crystals, and is freely soluble in water. (See *P. J. Tr.*, June 28, 1879; also *Sparteinæ Sulphas*, p. 1265.) By the action of potassium bichromate and sulphuric acid, *oxysparteine*,† $C_{15}H_{24}N_2O$, is formed, and by the action of hydrogen dioxide upon this, a deliquescent *trioxy-*

* Goldschmidt and Himmelmayr (*Apoth. Zeit.*, 1893, 566) give the following formula of scoparin: $C_{19}H_{16}O_8(OH)(OCH_3)$.

† *Oxysparteine*, $C_{15}H_{24}N_2O$. This is an alkaloidal oxidation product of sparteine, originally described by F. Ahrens (*Ber. Chem. Ges.*, 1891). It occurs in white, somewhat hygroscopic needles, melting at about 84° C., soluble in water, alcohol, ether, and chloroform. It has been found by Hurthle (*Arch. f. Exp. Path. u. Therap.*, 1892) to be a cardiac stimulant, decreasing the pulse-rate, but markedly increasing the arterial pressure and heart-work. The hydrochlorate, which occurs in large needles (often consolidated together) and is very soluble in water, has been used hypodermically by Dr. von Oefele in cases of *heart-failure*. The dose is half a grain (0·032 Gm.), rapidly increased to one and a half grains (0·097 Gm.). The system is said soon to become accustomed to it.

sparteine, $C_{15}H_{24}N_2O_3$, is obtained; if the hydrogen dioxide act upon sparteine itself, *dioxysparteine*, $C_{15}H_{24}N_2O_2$, is formed as a solid, crystallizing in prisms melting at 128·5° C. Zinc and hydrochloric acid reduce sparteine to *hydrosparteine*, $C_{15}H_{28}N_2$, a thick liquid boiling at from 281°–284° C. (Schmidt, *Pharmaceutische Chemie*, 3te Auf., Bd. ii. 1276.)

Medical Properties and Uses. Broom is diuretic and cathartic, and in large doses emetic, and has been employed with great advantage in *dropsy*, for which it was recommended by Meade, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce (30 C.c.) every hour till it operated by stool or urine. The seeds may be given in powder, in the dose of from ten to fifteen grains (0·65–1 Gm.).

Scoparin probably represents the diuretic and purgative influences of scoparius, although its physiological and therapeutic properties have not as yet been sufficiently investigated. Poisonous doses of *sparteine* cause in the lower animals tremblings, incoördination, increase of reflexes, clonic and tonic convulsions, embarrassment of the respiration, acceleration of the pulse, and enfeeblement of the heart, followed by gradual enfeeblement of all the functions, convulsions, and death from asphyxia. Sparteine paralyzes the respiratory centres and the motor centres of the spinal cord, and has a very feeble influence upon the muscles, lessening, though not destroying, their excitability. Dr. Laborde was the first to call attention to its action upon the heart, and his results have been confirmed by Griffe, Garand, and Masius. Under the influence of the alkaloid there is a very great increase in the size and height of the cardiac wave. If the dose have been a small one, the pulse will be at first accelerated. After larger doses there is a slowing of the pulse. Observers agree in stating that the arterial pressure is not materially changed unless the dose is toxic, when it steadily falls; but small doses weaken and larger ones paralyze the peripheral pneumogastric nerve. Upon the vaso-motor system sparteine appears to have no influence unless in large toxic doses, when it perhaps acts as a paralyzant. It does not represent the diuretic influence of scoparius. Prof. Sée affirms as the result of personal experience that sparteine is of very great value in *cardiac affections*, increasing the force of the cardiac beat, and especially producing regularity in cases of irregular cardiac action. For the latter purpose, he states, it is the most powerful remedy known. Other clinicians have recorded experience favorable to the value of sparteine, but the conclusion of Hiero Stoessel, that sparteine is inferior as a heart tonic to digitalis, and to be employed only as a succedaneum to that drug, probably indicates correctly the scope of its use. It has the great advantage of acting very quickly, the symptoms commencing about twenty minutes after its absorption, and reaching their maximum in four or five hours, but persisting one or two days. It is probably not safe to commence with doses greater than one-sixth of a grain (0·011 Gm.), although observers seem to be in accord in believing that much larger amounts are usually necessary. Voigt, Prior, Sée, and Leo all advise doses of one and a half grains (0·097 Gm.) repeated four or five times in the twenty-four hours. It is affirmed that no cumulative effects need be feared.

As the result of experiments upon the lower animals, Langlois and Maurange (*Archiv. de Phys. Norm. et Path.*, vii., 1895) believe that sparteine and oxysparteine are valuable remedies for the maintenance of cardiac action during chloroformization, acting partly by stimulating the heart, partly by depressing the pneumogastric nerve. G. G. Cottam asserts (*T. G.*, Nov. 1896), as the result of a clinical study, that one-tenth grain of the sparteine sulphate, given hypodermically just before the inhalation of chloroform, will prevent any cardiac depression from the anæsthetic.

SCUTELLARIA. U. S. Scutellaria. [Scullcap.]

(SCŪ'TĘL-LĀ'RĮ-Ą.)

"The herb of Scutellaria lateriflora, Linné (nat. ord. Labiatæ)." *U. S.*

Hoodwort, Madweed; Scutellaire, *Fr.*; Helmkraut, *G.*

Several species of Scutellaria have attracted attention. *Scutellaria galericulata*, or common *European scullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odor, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers. The indigenous species, *S. integrifolia*, L. (syn. *S. hyssopifolia*, L.), is intensely bitter, and might probably be found useful as a tonic.

Scutellaria lateriflora. L. *Sp. Pl.* (1753) 598. This is an indigenous perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue color, and disposed in long, lateral, leafy racemes. The

tube of the corolla is elongated, the upper lip concave and entire, the lower three-lobed. The plant grows in moist places by the sides of ditches and ponds in the United States and Canada.

The dried tops are officially described as "about 50 Cm. [twenty inches] long, smooth; stem quadrangular, branched; leaves opposite, petiolate, about 5 Cm. long, ovate-lanceolate or ovate-oblong, serrate; flowers in axillary, one-sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped; odor slight; taste bitterish." *U. S.* To the senses scullcap does not indicate, by any peculiar taste or smell, the possession of medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no very obvious effects, and probably is of no remedial value, although at one time it was esteemed as a remedy in *hydrophobia*. It has also been used in *neuralgic* and *convulsive affections*, *chorea*, *delirium tremens*, and *nervous exhaustion* from fatigue or over-excitement. (*A. J. P.*, xxiii. 370; *N. J. Med. Rep.*, v.; *Med. and Surg. Rep.*, 1870.) The so-called *scutellarin* is not a pure proximate principle. It is prepared by mixing a concentrated tincture with water, precipitating by alum, and then washing and drying, and given in doses varying from one to three or four grains (0·065–0·20 or 0·26 Gm.). Dose of the fluid extract, from one to two fluidrachms (3·75–7·5 C.c.).

SENEGA. U. S. (Br.) Senega.

(SĔN'Ē-GĄ.)

"The root of Polygala Senega, Linné (nat. ord. Polygaleæ)." *U. S.* "The dried root of Polygala Senega, Linn." *Br.*

Senegæ Radix, *Br.;* Senega Root, Senega Snakeroot; Polygale de Virginie, *Fr.;* Klapper-Schlangenwurzel, Senegawurzel, *G.;* Poligala Virginiana, *It.*

Besides *P. senega*, two other species have attracted some attention in Europe—*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but, as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.*

Polygala senega. L. *Sp. Pl.* (1753) 704; Willd. *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.* ii. 97; Barton, *Med. Bot.* ii. 111; *B. & T.* 29. This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five sepals, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved and two-celled, with two oblong-ovate, blackish, hairy seeds, slightly longer than the lobes of the caruncle. In *P. alba* (Nutt.) the seeds are silky and about twice the length of the caruncle lobes.

The *Polygala senega* grows in almost all parts of the United States east of the Rocky Mountains. It is collected for market in Kentucky and the States west and southwest of it, and also in Wisconsin and the Northwestern States. It was formerly abundant in Canada and the Northeastern Atlantic States, but through the activity of the collectors and the destruction of the forests it has been gradually almost exterminated; and in the Southwestern States the same process is going on. There are two varieties of the plant, the typical *P. senega*, the form found in the Northeastern United States, and the variety *latifolia*, which extends from Maryland and Pennsylvania to Michigan and Tennessee. This variety is distinguished by its height (from ten to twenty inches) and its very large, ovate or ovate-lanceolate leaves, which taper towards each end and attain a length of four inches. The root of commerce seems to be obtained from both varieties. It is brought into market in bales weighing from fifty to four hundred pounds.

Properties. As the root occurs in commerce,† it is of various sizes, from that of a straw

* A senega which was first used in Japan, and which has been referred by some writers to *P. japonica*, by others to *P. tenuifolia*, has been examined by Herr Reuter, who finds in it 0·8 per cent. of resin, traces of methyl salicylate, and 8·8 per cent. of an oil which has somewhat the odor of patchouli.

† The official senega, which is described in the text, is often known in commerce as *Southern senega*, or *small senega*, the roots seldom attaining the size of an ordinary lead-pencil, and four to five hundred of the dried roots being required to make a pound. These roots are marked with the characteristic keel, which is, however, much more distinct in the young than in the old roots. In the decade between 1870 and 1880, true senega root began to be more or less replaced in the American market by a larger root, collected in Wisconsin and Minnesota and farther west. This is the *northern*, the *white*, the *false*, or the *large senega* of trade. It is a much larger root than true senega, probably eighty to one hundred to the pound. The knot at the top of the root is from one to three inches in

to that of the little finger, presenting a thick knotty head, which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and with a projecting keel-like line, extending along its whole length. The epidermis is corrugated, transversely cracked, of a yellowish-brown color in the young roots, and brownish gray in the old. In the smaller branches the color is a lighter yellow. The bark is thick, hard, and resinous, and whitish in its interior; it contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The color of this is gray. On microscopic examination the bark is seen to be composed of—1st, an outer layer, composed of a series of tubular cells; 2d, a middle layer of thin-walled, parenchymatous cells; 3d, an inner layer containing bast-cells. The keel is produced by the excessive development of this last layer of bark upon one side. There is no medulla. The odor of senega is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acrid, leaving a peculiar irritating sensation in the fauces. These properties, as well as the medical virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent. The root was analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulon d'Astafort, Folchi, and Trommsdorff, and subsequently by M. Quevenne. The virtues of senega appear to reside chiefly, if not exclusively, in the acrid principle first called *senegin* or *polygalic acid*, which is now recognized as being merely saponin. Quevenne obtained it pure by the following process. Powdered senega is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling, it deposits the principle in question

Senega, transverse section, magnified.

diameter; below it the root abruptly contracts to from half an inch to an inch in diameter; it is usually from eight to ten inches long, more fleshy and much less contorted than true senega, nearly free from small rootlets, but breaking up below in from four to eight descending branches; very light-colored, with the ligneous portion thick and regular, and in the circular outlines of the section, with the keel rudimental or not rarely altogether absent. The taste is similar to that of true senega, but somewhat more mucilaginous and less rapidly acrid. In structure, false senega root is very similar to the true root; it has, indeed, been asserted that there are anatomical differences between the two senegas, but O. Linde (*P. J. Tr.*, xvi. 724) has been unable to make out any such differences. According to L. E. Sayre (*A. J. P.*, Sept. 1897), it is not possible to distinguish the two drugs when powdered. For description of the roots of a number of species of Polygala, see *Flora*, Jan. 1886.

There has been much discussion as to the plant which yields false senega. By some it was thought to be the product of *Polygala boykinii*. Nuttall and Messrs. J. U. and C. G. Lloyd identified the fresh plant as a variety of *P. senega*, intermediate between the typical form and *P. latifolia*. *P. boykinii* is a Southern plant, and it appears most probable (see *A. J. P.*, 1889) that the plant which yields the drug is *Polygala alba* of Nuttall, whose habitat extends from Texas northward to the British possessions and southward into the mountainous districts of Mexico. Pursh and Nuttall, also Torrey and Gray, have at times expressed doubt as to the specific difference of the species from *P. senega*, but according to Rothrock it possesses the following characters: "Leaves linear to oblanceolate, sessile or barely petioled, margins slightly revolute; stem leafy half-way to the summit; flowers deciduous, leaving the rachis roughened after their fall."

in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. M. Quevenne found it, when given to dogs, to occasion vomiting, and much embarrassment in respiration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs; and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of senega in croup. (*Journ. de Pharm.*, xxii. 449, and xxiii. 227.) M. Bolley showed that the active principle was resolvable by hydrochloric acid into glucose and a peculiar substance called *sapogenin*. Rochleder (*Chem. Centralbl.*, 1867, p. 925) confirmed this view of the identity of polygalic acid and saponin. Later investigators assert the existence of two homologous principles in the senega root,—*senegin*, $C_{17}H_{28}O_{10}$, and *polygalic acid*, $C_{19}H_{30}O_{10}$. That this latter is a variety of saponin is no doubt true. Christophson (*Journ. Pharm.*, 1874) and Schneider (*Arch. d. Pharm.* [3], 7, 394) have also thoroughly established the existence of saponin in senega root. According to the researches of Trommsdorff and Schneider, saponin is contained solely in the bark, the woody tissues being inert. (See *Quillaja*, p. 1133.) L. Reuter (*Arch. d. Pharm.*, 1889, 309 and 452) finds that the constituents of senega root are fixed oil and resin, traces of volatile oil (a mixture of valerianic ether and methyl salicylate), sugar (7 per cent.), senegin or saponin (from 2 to 5 per cent.), yellow coloring matter, and malates. The quantity of methyl salicylate* varied in different samples from 0·25 to 0·33 per cent. See also Schroeder's analysis (*A. J. P.*, 1896, 178). Kain (*Pharm. Zeit.*, 1898, 562) states that he has discovered a lævo-rotatory glucoside distinguished from saponin by its mild taste, solubility in absolute alcohol, and in its not giving a precipitate with barium hydrate.

From the experiments of M. Quevenne it appears that senega yields its virtues to water, cold or hot, and to boiling alcohol, and that the extracts obtained by means of these liquids have the sensible properties of the root. But under the influence of heat a portion of the acrid principle unites with the coloring matter and coagulated albumen, and thus becomes insoluble in water; and the decoction, therefore, is not so strong as the infusion, if time is allowed, in the formation of the latter, for the full action of the menstruum. In forming an aqueous extract, the infusion should be prepared by percolation, as it is thus most concentrated, and consequently requires less heat in its evaporation. In preparing the infusion, the temperature of the water, according to M. Quevenne, should not exceed 104° F.

The roots of *Panax quinquefolium*, or ginseng, were at one period frequently mixed with the senega, but are easily distinguishable by their shape and taste. The roots of *Gillenia trifoliata* and *Asclepias vincetoxicum*, L. (*P. J. Tr.*, ix. 411), and of *Triosteum perfoliatum* (see PART II.), are noted as occurring in commercial senega; they are readily detected by the absence of the keel-like line.

Medical Properties and Uses. Senega is a stimulating expectorant and diuretic, and in large doses emetic and cathartic. It appears, indeed, to excite more or less all the secretions, proving occasionally diaphoretic and emmenagogue, and increasing the flow of saliva. Its action, however, is especially directed to the lungs; and its expectorant virtues are those for which it is chiefly employed. It was introduced into practice about a century ago by Dr. Tennant, of Virginia, who recommended it as a cure for the bite of the *rattlesnake*, and in various pectoral complaints. As an expectorant it is employed in cases not attended with acute inflammatory action, or in which the inflammation has been in great measure subdued. It is peculiarly useful in *chronic catarrhal affections*, in the secondary stages of *croup*, and in *capillary bronchitis*. Employed so as to purge and vomit, it has proved useful in *rheumatism*; and some cases of *dropsy* are said to have been cured by it. It has also been recommended in *amenorrhœa*. The dose of powdered senega is from ten to twenty grains (0·65–1·3 Gm.); but the medicine is never used in substance. The dose of the syrup is from one to two fluidrachms (3·75–7·5 C.c.). Polygalic acid may be employed in the dose of from the fourth of a grain to a grain (0·016–0·065 Gm.), and may be administered either in pill, capsule, or mixture. For a formula for its preparation, see *A. J. P.*, 1860, 150.

* Methyl salicylate occurs in very many, if not all, of the species of the genus Polygala. (See paper by Kremers and James, *Pharm. Review*, xvi.)

CASSIA. See *Cassia Fistula.*

The plants which yield senna belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded together by Linnæus in a single species, which he named *Cassia senna.* Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt and had an opportunity of examining the plant in its native country. Besides the official species, it is probable that *C. lanceolata* of Forskhal and *C. æthiopica* of Guibourt contribute towards commercial senna. The leaves of a number of species of Cassia are utilized like senna leaves in the respective countries in which they grow, among which may be mentioned *C. marylandica*, L.; *C. cathartica*, Mart.; *C. rugosa*, Don; *C. splendida*, Vog.; *C. lævigata*, Willd.; *C. multijuga*, Rich.; and *C. chamæcrista*, L.

Cassia acutifolia. Delile, *Flore d'Egypte* (1812), 219.—*C. senna.* Linn. *Sp. Pl.* 377.—*C. lanceolata.* Collad. *Hist. Cass.* 93, t. 15.—*C. lenitiva.* Bisch. *Bot. Zeit.* (1850) 885.—*Senna acutifolia.* Batka, *Proc. Linn. Soc.* (1854) 282. This is described as a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts. The leaves are alternate and pinnate, with glandless footstalks, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green color. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-colored seed. *C. acutifolia* grows wild in great abundance in Upper Egypt, Nubia, Sennaar, and other parts of Africa. This species furnishes the greater part of the variety known in commerce by the name of Alexandria senna.

Cassia angustifolia. Vahl, *Symb. Bot.* i. 29.—*C. elongata.* Lemaire, *Journ. de Pharm.* (1821) 345; Fée, *Journ. de Chim. Méd.* vi. 232; Carson, *Illust of Med. Bot.* i. 36, pl. 29. This name was conferred by M. Lemaire upon the plant from which the India senna of commerce is derived. The botanical description was completed by M. Fée from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Dr. Wallich afterwards succeeded in raising the plant from seeds found in a parcel of senna taken to Calcutta from Arabia; and it has been described by Dr. Royle, Wight and Arnott, and Dr. Lindley. As usually grown, it is annual; but with care it may be made to live through the year, and then assumes the character of an undershrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inward so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from an inch to twenty lines. The petioles are without glands; the stipules minute, spreading, and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the apex, and an inch and a half long by somewhat more than half an inch broad. This plant is found in Southern Arabia and on the coast of East Africa from Mozambique to the Somali land. It has been said to grow in the interior of India, and is cultivated at Tinnevelly for medical use.

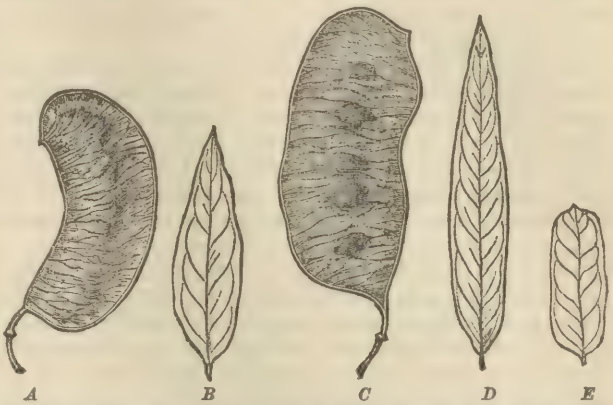
Cassia obovata. Colladon, *Hist. Cass.* 92, t. 15. The stem of this species is rather shorter than that of *C. acutifolia*, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown color, and covered with a very short down, which is perceptible only by the

aid of a magnifying glass. They contain from eight to ten seeds. This species grows wild in Syria, Egypt, Senegambia, and Jamaica. (*P. J. Tr.*, Sept. 1867.) It has been cultivated successfully in Italy, Spain, and the West Indies. It is said to be no longer gathered for senna, although its leaflets and pods occur in Alexandria senna.

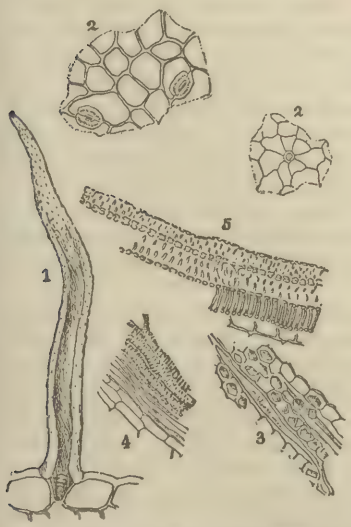
C. lanceolata of Forskhal (*Fl. Ægypt. Arab.*, 85; syn. *C. Sophera*, L., *Sp. Pl.* 379), found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference of opinion, however, exists upon this point. De Candolle considered it a variety of the *C. acutifolia* of Delile, from which it differs chiefly in having leaflets with glandular petioles; and, as Forskhal's description preceded that of Delile, he designated the species by the name of *C. lanceolata*. Forskhal's plant has been supposed by some to be the source of the India or Mocha senna; but the leaflets in this variety are much longer than those of *C. lanceolata*, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of Abu-Arisch, whence it is taken by the Arabs to Mecca and Jedda. This is probably the *C. lanceolata* of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of *Mecca senna*.

Cassia æthiopica of Guibourt, *Hist. Drogues*, 3e éd., iii. 219 (*C. ovata* of Mérat), formerly confounded with *C. acutifolia*, is considered by Dr. Lindley to be a distinct species. It grows in Nubia, Fezzan, to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.

Several varieties of this valuable drug are known in commerce. Of these, four have been received in America,—the Alexandria, the Tripoli, the India, and the Mecca senna,—but only two are recognized by the Pharmacopœia.



1. Alexandria Senna. Though the name of this variety is derived from the Egyptian port at which it is shipped, it is in fact gathered very far in the interior. The Alexandria senna does not consist exclusively of the product of one species of Cassia. The history of its preparation is not destitute of interest. The senna plants of Upper Egypt yield two crops annually, one in spring and the other in autumn. They are gathered chiefly in the country beyond Syene. The natives cut the plants, and, having dried them in the sun, strip off the leaves and pods, which they pack in bales and send to Boulak, in the vicinity of Cairo, the great entrepôt for this article of Egyptian commerce. This senna from Upper Egypt, consisting chiefly though not exclusively of the product of *C. acutifolia*, was here formerly mixed with the leaflets of *C. obovata*, brought from other parts of Egypt, and even from Syria, with the leaves of *Cynanchum oleæfolium* (*C. argel* of Delile, *Solenostemma argel*, Hayne), known commonly by the name of *argel* or *arguel*, and sometimes with those of *Tephrosia apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together were five parts of *C. acutifolia*, three of *C. obovata*, and two of *Cynanchum*. Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is no such uniformity in the constitution of Alexandria senna; and, though the three chief ingredients may still sometimes be found in it, they are not in the same fixed proportions; and not unfrequently the Cynanchum leaves are wholly wanting. This variety of senna is often called in French pharmaceutical works *séné de la palthe*, a name derived from an impost formerly laid upon it by the Ottoman Porte. A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients: 1, the leaflets of *C. acutifolia*, characterized by their acute form, and their length, almost always less than an inch; 2, the leaflets of *C. obovata*, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3, the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; 4, the leaves of *Cynanchum oleæfolium*, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter color, and the regularity of their base. In this last character they



A *B* *C* *D*

A, leaf of Cynanchum oleæfolium: *B*, leaf of Tephrosia apollinea; *C*, fruit of the same; *D*, leaf of Coriaria myrtifolia. (After De Lanessan.)

strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. Discrimination between this and the other ingredients is of some importance, as the Cynanchum must be considered an adulteration. It is said by the French writers to produce hypercatharsis and much irritation of the bowels, but was found by Christison and Mayer to occasion griping and protracted nausea, with little purgation. The flowers and fruit of the Cynanchum were also often present, the former white and in small corymbs, the latter an ovoid follicle rather larger than an orange-seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the *acutifolia* or *obovata*, equalling in this respect the Cynanchum, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. The leaflets and fruit of *Tephrosia apollinea*, which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. As now imported, Alexandria senna is often quite free from the leaves of Cynanchum, and may have few or none of the leaflets of obovate senna. It is probably brought directly to Alexandria from Upper Egypt, without having undergone intermixture at Boulak or other intervening place.

A, fruit of Cassia acutifolia; *B*, leaf of same; *C*, fruit of Cassia angustifolia; *D*, leaf of same; *E*, leaf of Cassia ovalifolia. (After De Lanessan.)

Senna leaf. 1, section of epidermis with a long hair; 2, epidermis with stomata; 3, bast-cells with crystals from a vein; 4, fragment of the nerve of the leaf; 5, wood vessels out of the petiole.

In Europe, this senna is said to have been sometimes adulterated with the leaflets of *Collutea arborescens*, or bladder senna, and the leaves of *Coriaria myrtifolia*, a plant of Southern Europe, said to be astringent and even poisonous. An account of these plants is given in PART II. The leaflets of the Coriaria are ovate-lanceolate, grayish green with a bluish tint, and are readily known, when not too much broken up, by their strongly-marked midrib and two lateral nerves running from the base nearly to the summit. Another addition to Alexandria senna has been detected by M. Lacroix, of Mâcon, France, in the leaves of the *Globularia turbith* (*Globularia alypum*, Linn.), which seem to have taken the place of the *Colutea arborescens*, because more closely resembling the senna leaflet. The leaves of the Globularia are spatulate, much enlarged towards the upper end, rounded at the extremity, but always terminating in a short sharp point. Besides, they are brown, thick, firm, and hard to the touch, while those of the Colutea are green, very thin, and soft. They have an acrid, very bitter taste, but are without nauseous odor. They are asserted to be cathartic, but milder than senna, and capable of being substituted for it in twice the dose. (*Journ. de Pharm.*, 4e sér., i. 413.) In detecting the adulteration of senna, the apothecary may avail himself not only of the general physical characteristics of the leaves, but also of the fact that whilst the senna leaf, containing no tannic acid, does not precipitate ferric chloride, most leaves used in adulteration do alter the ferric solution. The microscopic characteristics of the false

leaves, though varying greatly, are almost always very different from those of senna. In the senna leaflets the epidermis from the upper and under surface is very similar. The stomata are numerous; the epidermal hairs are unicellular and deciduous, leaving, when detached, a base which has the appearance of an annular pad, around which the neighboring cells seem to radiate. The parenchyma of the cell has a thick epidermis, and is divided into three layers, the uppermost and lowest of which consist of palisade tissue, and are separated by a zone of very small, rounded, parenchymatous cells. Stellate crystals of calcium oxalate are scattered throughout the parenchyma; and prismatic crystals, one in each cell, occur clustered around the bast tissue of the principal veins.

Alexandria Senna is officially described as "leaflets about 25 Mm. long and 10 Mm. broad, lanceolate, or lance-oval, subcoriaceous, brittle, rather pointed, unequally oblique at the base, entire, grayish-green, somewhat pubescent, of a peculiar odor, and a nauseous, bitter taste. It should be free from stalks, and from Argel leaves (the leaves of *Solenostemma Argel* Hayne, nat. ord. *Asclepiadeæ*), which are frequently present; these leaves are thicker, one-veined, wrinkled, glaucous, and even at the base." *U. S.*

2. Tripoli Senna. Genuine Tripoli senna consists in general exclusively of the leaflets of one species of Cassia, formerly considered to be a variety of *C. acutifolia*, but now admitted to be distinct, and named *C. æthiopica*. The leaflets, however, are much broken up; and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of *C. acutifolia* in Alexandria senna; and their nerves are much less distinct. The general opinion at one time was that it was brought from Sennaar and Nubia to Tripoli in caravans; but, it is reasonably asked by M. Fée, how could it be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert? It is probably collected at Fezzan, immediately south of Tripoli. For a microscopical description of Alexandria senna, see *Proc. A. P. A.*, 1882, p. 238.

3. India Senna. This variety is in Europe sometimes called *Mocha senna*, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of *Cassia elongata*, with some of the leafstalks and pods intermixed. The eye is at once struck by the great length (about two inches) and comparative narrowness of the leaflets, so that the variety may be readily distinguished. The pike-like shape of the leaflet has given rise to the French name of *séné de la pique*. Many of the leaflets have a yellowish, dark-brown, or blackish color, probably from exposure after collection; and the variety has commonly in mass a characteristic dull tawny hue. It is generally considered inferior in purgative power. Leaflets of a senna resembling the Indian were brought by Dr. Livingstone from Southern Africa, where the plant grows abundantly. (*P. J. Tr.*, xvii. 499.) "*India Senna* consists of leaflets from 3 to 5 Cm. long, and 10 to 15 Mm. broad; lanceolate, acute, unequally oblique at the base, entire, thin, yellowish-green or dull green, nearly smooth; odor peculiar, somewhat tea-like; taste mucilaginous, bitter, and nauseous. It should be free from stalks, discolored leaves, and other admixtures." *U. S.*

A variety of India senna has reached this country which is the produce of Hindostan, being cultivated at Tinnevelly, and probably other places in the south of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is the same as that from which the common Indian senna is derived. The drug is exported from Madras to England, where it is known by the name of *Tinnevelly senna*. It is a fine unmixed variety, consisting of unbroken leaflets, from one to two or more inches long, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green color. Mr. T. B. Groves, however, states as the result of his experiments that Tinnevelly senna contains only two-thirds as much of the active principle as does the Alexandrian. (*P. J. Tr.*, Oct. 1868, p. 202.)

4. Mecca Senna. After the publication of the fifth edition of this Dispensatory, a variety of senna was imported under the name of *Mecca senna*, consisting of the leaflets, pods, broken stems, and petioles of a single species of Cassia. The leaflets were oblong-lanceolate, on the average longer and narrower than those of *Cassia acutifolia*, and shorter than those of *Cassia elongata*. The variety in mass had a yellowish or tawny hue, more like that of India than like that of Alexandria senna. May it not have been the product of the *Cassia lanceo-*

lata of Forskhal? We might infer so from the name, and from the character of the leaflet. Landerer, however, speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of Mecca senna, which he says comes from the interior of Africa.

Much study has been given to the question of distinguishing the powder of Alexandria and India senna by means of the microscope. (See papers by Sayre, *A. J. P.*, 1896, 1897; Schneider, *American Druggist*, 1897; Denniston, *Pharm. Review*, vol. xvi.) As a result of these studies it is asserted that it is possible to take advantage of the greater hairiness of the Alexandria senna as a practical distinction, it being alleged that a piece of the epidermis of Alexandria leaf contains always twice as many hairs as does a similar-sized shred of epidermis from the India senna. It is especially proposed to count the number of epidermal cells between two hairs or their scars, the average distance of the hairs from one another being in the Alexandria senna three epidermal cells, and in the India six cells. Advantage may also be taken of the difference in the neighboring cells of the stomata; in the majority of stomata, in each case, there are two of the neighbor-cells, but in India senna the proportion is one having three neighbor-cells to seven having two, and in the Alexandria the proportion is one having three to two having two.

Commercial senna is prepared for use by *garbling*, or picking out the leaflets, and rejecting the leafstalks, the impurities, and the leaves of other plants. The pods are also rejected by some apothecaries. They were preferred by the Arabian and mediæval physicians of Europe to the leaves, whilst Pereira states that they are much milder in their operation than the leaflets. This has been explained by the researches of E. F. Salmon, who has found that they contain about 25 per cent. more cathartin than the leaves, but no resinous principle or volatile oil. (*P. J. Tr.*, Oct. 1889.) The griping of senna being largely due to the resin, it is *a priori* to be expected that the pods would act more kindly than the leaves. Dr. A. W. Macfarlane has found this to be actually the case. From six to twelve pods for the adult, or from three to six for the young or very aged, infused in a claret-glass of cold water, in his experience, act very kindly but very thoroughly upon the whole intestine.*

Properties. The odor of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, *Pharm. Centralbl.*, Feb. 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown color, and has the odor and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired; but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (*Pharm. Centralbl.*, 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown color as to water; but rectified alcohol and ether, digested upon the powdered leaves, become of a deep olive-green.

Lassaigne and Feneulle first isolated a substance to which they gave the name of *cathartin*, but it proved to be a mixture; Bley and Diesel (*Pharm. Centralbl.*, 1849, p. 126) isolated a yellow coloring matter, which they called *chrysoretin*, but which Martius identified as *chrysophan*; Ludwig (*Arch. d. Pharm.* (2), 119, p. 42, and 190, p. 69) obtained two bitter principles, *sennapicrin* and *sennacrol*, the first insoluble, the second soluble in ether; but the active purgative principle was first discovered in 1866 by Dragendorff and Kubly (*Viertelj. f. Prakt. Pharm.*, 16, pp. 96 and 337), who found it to be a glucoside of weak acid character, and named it *cathartic acid*. Mr. Thos. B. Groves, in 1868 (*P. J. Tr.*, 1869, p. 196), unaware of Dragendorff and Kubly's discovery, isolated the same principle, and found for it the same reactions. For a method of preparing cathartic acid, by Mr. Ralph Stockman, see *P. J. Tr.*, 1885, p. 740. Its formula is given as $C_{180}H_{96}N_2SO_{82}$, and by boiling its alcoholic solution with acids it yields *cathartogenic acid* and sugar. Gensz (*A. J. P.*, 1893, 334), who prepared it later by the

* Mr. E. F. Salmon prepares a black-looking, perfectly tasteless liquid, said to be active in doses of one-half to two fluidrachms, by the following formula. Macerate one pound of bruised pods in six pints of cold distilled water for twenty-four hours; decant; macerate again for twelve hours in three pints of cold water; evaporate the strained liquors to thirteen fluidounces; add four ounces of diluted alcohol; filter after a few hours. (*Chemist and Druggist*, 1889.)

method of Kubly and Stockmann, gives the formula $C_{30}H_{36}NO_{15}$. It is amorphous, difficultly soluble in cold water, readily soluble in boiling water. The best solvent is a 30 to 40 per cent. alcohol; ether, benzene, chloroform, and petroleum ether are without solvent action. Alkalies with heat decompose it. It is prepared by partially precipitating with alcohol infusion of senna, concentrating to a syrupy consistence *in vacuo*, filtering, treating the filtrate with a large proportion of absolute alcohol, and repeatedly dissolving in water, and precipitating by alcohol the precipitate thus obtained. It is purified by submitting it (dissolved in moderately strong hydrochloric acid) to dialysis on a diaphragm of parchment paper, cathartic acid having strong colloidal properties. Mr. Groves found that ammonium cathartate purged moderately in the dose of three and three-quarters grains, with considerable griping, and that of certain mixed cathartates seven and a half grains purged violently, with much griping and sickness, and continued to act through most of a day. He considers four grains a fair dose. It should be given in connection with an aromatic and a saline cathartic. *Magnesium cathartate* is soluble. The salts of this acid in aqueous solution are decomposed and rendered inert by long exposure to heat in contact with the air. (Groves, *P. J. Tr.*, Oct. 1868, 200–1.) Dragendorff and Kubly also found chrysophanic acid in small proportions, the two substances, *sennacrol* and *sennapicrin*, previously mentioned, and a peculiar non-fermentable saccharine principle, with the formula $C_{21}H_{44}O_{19}$, which they named *catharto-mannite*. (*Journ. de Pharm.*, 4e sér., v.) Mr. A. Seidel proposes the name of *sennit* for catharto-mannite, and gives a process for its preparation in *A. J. P.*, 1885.

Some results of experiments on the properties of senna which more particularly concern the pharmacist are noted in a paper contained in the *Journal de Pharmacie* (Janv. 1874, p. 80), and require to be mentioned here, because they tend to fix certain points which are left undetermined in the above statement. An extract made by evaporating in the air an aqueous infusion of senna possesses but partially the purgative properties of the leaves. If the extract be redissolved in a large quantity of water, and the solution be again evaporated, the extract now obtained will be quite inert. It follows that a prolonged decoction of senna destroys its cathartic powers. The presence of an alkali in the decoction increases the rapidity of the destruction. An infusion of senna in lime water, heated to the boiling point, and then deprived of lime by a stream of carbonic acid, becomes inert. An infusion of senna, made to boil after the addition of caustic potassa, and then neutralized by an acid, is also inert. The mineral acids destroy the purgative powers of senna, but less energetically than the alkalies; the vegetable acids exercise the same power but feebly. Concentrated alcohol does not dissolve the active principle, which is soluble in cold water. It was Heerlein who first determined the complete want of purgative power in the pure alcoholic extract of senna. Nevertheless, this extract possesses in a high degree the odor and taste of senna, and, taken internally, without purging, imparts a deep-yellow color to the urine, which the alkalies change to red. The leaves exhausted by alcohol have all their purgative effect, but lose the power of affecting the urine so that an alkaline solution shall color it red. These facts prove that chrysophanic acid is not the purgative principle of senna. The fact that alcohol removes the odor and taste of senna without affecting its purgative action may sometimes be advantageously applied in cases in which the taste of senna is extremely offensive. Mr. L. Siebold, after experimenting with senna leaves washed with alcohol, arrived at the following conclusions. 1. Strong spirit does not remove any of the active principle (cathartic acid) from senna leaves. 2. The therapeutic action of cathartic acid is assisted by one or more of the constituents yielded by senna to strong spirit, though the latter produce no purgative effect when taken alone. 3. Senna exhausted by alcohol is a reliable and pleasant purgative, but somewhat weaker in its action than the unexhausted leaves.*

Incompatibles. Many substances produce precipitates with the infusion of senna; but it does not follow that they are all medicinally incompatible, as they may remove only inert ingredients. Cathartic acid is precipitated by infusion of galls and solution of lead subacetate. Lead acetate and tartarized antimony, which disturb the infusion, have no effect upon the solution of this substance.

Medical Properties and Uses. Senna was first used as a medicine by the Arabians.

* *Vinum Sennæ. Senna Wine.* Alexandria Senna Leaves, *one and a half ounces;* Sherry Wine, *twenty-seven ounces.* Macerate for eight days, press, and strain; then add five grains of Gelatin, dissolved in two and a half drachms of distilled water, and then the following: Tincture of Orange Peel, *one ounce;* Tincture of Ginger, *a half-ounce;* Aromatic Tincture, *eighty minims;* Honey, *two ounces.* Again allow to stand for ten days, and filter. This wine is reputed to be an excellent aperient for persons suffering from hemorrhoids. It should be taken in tablespoonfuls, according to the effect desired. (*Dieterich's Pharm. Manual.*)

It was noticed in their writings as early as the ninth century; and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for *fevers* and *febrile complaints*, and other cases in which a decided but not violent impression is desired. A disadvantage is that it is apt to produce severe griping. This effect, however, may be obviated by combining with the senna some aromatic, and some one of the alkaline salts, especially potassium bitartrate, potassium tartrate, or magnesium sulphate. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the saline substances to their influence in promoting the solubility of that principle, is not satisfactory. The purgative effect of senna is considerably increased by combination with bitters,—a fact noticed by Cullen, and abundantly confirmed by subsequent experience. The decoction of guaiac is said to exert a similar influence. Senna yields one or more of its principles to the urine, as, from twenty to thirty minutes after it has been taken, this secretion acquires the property of being reddened by ammonia. (*Journ. de Pharm.*, Aôut, 1863.) Senna taken by nurses is said to purge sucking infants, and an infusion injected into the veins operates as a cathartic. The dose of senna in powder is from half a drachm to two drachms (1·95–7·8 Gm.); but the drug is never prescribed in this form. In official preparations "Tinnevelly senna may be used in place of Alexandria senna." *Br.* 1885. Dose of cathartic acid as a laxative from 0·25 to 0·4 Gm.

SERPENTARIA. U. S. (Br.) Serpentaria. [Virginia Snakeroot.]

(SËR-PĘN-TĀ'RĮ-Ą.)

"The rhizome and roots of Aristolochia Serpentaria, Linné, and of Aristolochia reticulata, Nuttall (nat. ord. Aristolochiaceæ)." *U. S.* "The dried rhizome and roots of Aristolochia Serpentaria, Linn., or of Aristolochia reticulata, Nutt." *Br.*

Serpentariæ Rhizoma, *Br.;* Serpentary Rhizome; Couleuvrée de Virginie, Serpentaire de Virginie, *Fr.;* Virginianische Schlangenwurzel, *G.;* Serpentaria Virginiana, *It., Sp.*

Many species of Aristolochia have been employed in medicine. The roots of all of them are tonic and stimulant; and their supposed possession of emmenagogue properties has given origin to the name of the genus. *A. clematitis*, *A. longa*, *A. rotunda*, and *A. pistolochia* are still retained in many official catalogues of the continent of Europe, where they are indigenous. The root of *A. clematitis* is very long, cylindrical, as thick as a goose-quill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown color, a strong, peculiar odor, and an acrid, bitter taste; that of *A. longa*, L., is spindle-shaped, from a few inches to a foot in length, of the thickness of the thumb or thicker, fleshy, very brittle, grayish externally, brownish yellow within, bitter, and of a strong, disagreeable odor when fresh; that of *A. rotunda*, L., is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish yellow internally, and similar to the preceding in odor and taste; that of *A. pistolochia*, L., consists of numerous slender yellowish or brownish fibres, attached to a common head, and possessed of an agreeable aromatic odor, with a taste bitter and somewhat acrid. Many species of Aristolochia growing in the West Indies, Mexico, and South America have attracted attention for their medicinal properties; and some, like our own snakeroot, have acquired the reputation of being antidotes for the bites of serpents. *A. cymbifera*, Martius, is much used in Brazil under the names of *milhommen*, *jarra*, or *jarrinha*, and probably has medical activities similar to those of the official species.* In the Argentine Republic the root of *A. argentina* is used as a diuretic and diaphoretic, especially in *rheumatism*. In the East Indies *A. indica* is employed for similar purposes with the European and American species; and the Arabians are said by Forskhal to use the leaves of *A. sempervirens* as a counter-poison. *A. fœtida* of Texas and Mexico, or *Yerba del Indio*, is used as a local stimulant to foul ulcers.† A number of species of Aristolochia are employed as a remedy for snake-bites in various parts of the world, as *A. serpentaria*, L., in North America; *A. maxima*, L. (the rhizome of which is called *Guaco od. Contra Capitano*), in South America; *A. anguicida*, L., in the Antilles; *A. brasiliensis*, Mart. et Zucc.; *A. cymbifera*, Mart. et Zucc.; *A. macroura*, Gom.; *A. trilobata*, L., etc. There is

* *Brazilian Aristolochia* as it comes into the European markets consists of pieces about 10 Cm. (4 inches) long, gray-brown, longitudinally wrinkled, the thickest roots being split; the transverse section shows a rather thick bark, and a ligneous cylinder, which is distinctly radiating, and contains wide dotted ducts and wood-fibres; the bark and medullary rays contain much starch, and, in numerous but slightly enlarged cells, a mixture of yellow resin and volatile oil. The taste and odor are warm and camphoraceous.

† Henry Trimble and S. S. Jones found in this root fixed oil, resin, tannin, coloring matter, lignin, albuminoids, mucilage, etc. (*A. J. P.*, 1886, 113.)

no sufficient reason for supposing that any of them is effective. We have in the United States six species, of which four—*A. serpentaria*, *A. hirsuta*, *A. hastata*, and *A. reticulata*—contribute to furnish the snakeroot of the pharmacies.

Aristolochia serpentaria. L. *Sp. Pl.* (1753) 961; Willd. *Sp. Plant.* iv. 159; Bigelow, *Am. Med. Bot.* iii. 82; Barton, *Med. Bot.* ii. 41; *B. & T.* 246. This species of Aristolochia is an herbaceous plant, with a short rhizome and numerous slender roots. Several stems often rise from the same rhizome. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green color, and supported on short petioles. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. The tube of the calyx is curved like the letter S, enlarged at the base (ovary) and at its throat, the short limb being obtusely three-lobed. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is fleshy and from three- to six-lobed. The fruit is an hexangular, six-celled capsule, containing several small flat seeds. The plant grows in rich shady woods throughout the Middle, Southern, and Western States, abounding in the valley of the Ohio and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania, West Virginia, Ohio, Indiana, and Kentucky, and is brought eastward chiefly by the routes of Wheeling and Pittsburg. As it reaches Philadelphia, it is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with adhering dirt.

Serpentaria rhizome, transverse section.

A. hirsuta. Muhlenberg, *Catalogue*, 81; Bridges, *A. J. P.* xiv. 121. In Muhlenberg's *Catalogue* this species was named without being described; and botanists, supposing from the name that it was identical with *A. tomentosa*, generally confounded the two plants. In *Index Kewensis* *A. hirsuta*, Muhl., is given as a synonym for *A. tomentosa*, Sims. A description of *A. hirsuta* in the handwriting of Muhlenberg, and a labelled specimen of the plant, in the possession of the Academy of Natural Sciences of Philadelphia, have been found to correspond with a dried specimen from Virginia. *A. tomentosa* is a climbing plant, growing in Missouri and Southern Illinois to Alabama and Florida, and ascending to the summit of the highest trees. It has a thick, creeping root, entirely different in shape from that of the official species, though possessed of an analogous odor. *A. hirsuta* has a root like that of *A. serpentaria*, consisting of a knotty caudex, sending out numerous slender simple fibres, sometimes six inches in length. From this arise several jointed, flexuose, pubescent stems, less than a foot high, with one or two pubescent bracts, and several large roundish-cordate leaves, of which the lower are obtuse, the upper abruptly acuminate, and all pubescent on both sides and at the margin. From the joints near the root originate from one to three solitary peduncles, each bearing three or four leafy bracts and one flower. The peduncles, bracts, and corolla are all hairy. This species grows in Virginia, West Virginia, and perhaps other parts of the West and South. It probably contributes to the serpentaria of commerce, as its leaves have been found in bales of the drug.

A. hastata. Nuttall, *Gen. of N. Am. Plants*, 200.—*A. sagittata.* Muhlenberg, *Catal.* This is now considered to be nothing more than a variety of *A. serpentaria*, from which it differs in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from

that of the official plant, and is frequently mixed with it, as is proved by the presence of the characteristic hastate leaves in the parcels brought into market.

A. reticulata. Nuttall, *Trans. Am. Phil. Soc.* (1837) 162; Bridges, *A. J. P.* xvi. 118; Carson, *Illust. of Med. Bot.* ii. 32, pl. 77. This plant was probably first observed by Mr. Nuttall, as a specimen labelled "*A. reticulata*, Red River," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From a root similar to that of *A. serpentaria* numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bracts at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the ovary. The hexangular capsule is deeply sulcate. This species grows from Virginia to Louisiana, Texas, Arkansas, and the Indian Territory.

Bales of a variety of serpentaria were some years since brought to Philadelphia which is certainly the product of this species, as specimens of all parts of the plant have been found in the bales, and the roots, which differ somewhat from those before known, are homogeneous in character. One of these bales was brought from New Orleans, and was said to have come down the Red River and to have been collected by the Indians. The chief difference between this and the ordinary Virginia snakeroot is in the size of the radicles, which are much thicker and less interlaced in the new variety. Each root has usually a considerable portion of one or more stems attached to the caudex. The color is yellowish. The odor and taste are scarcely if at all distinguishable from those of common serpentaria; and there is no doubt that the root is equally effectual as a medicine. From a chemical examination by Mr. T. S. Wiegand, it appears to have the same constituents, and to differ only in containing a rather larger proportion of gum, extractive, and volatile oil.

Mr. J. A. Ferguson (*A. J. P.*, 1887, p. 481) found in the rhizome volatile oil, resin, tannin, mucilage, glucose, malic acid, extractive, albuminoids, lignin, etc.

Properties. Virginia snakeroot is officially described as follows: "The rhizome is about 25 Mm. long, thin, bent; on the upper side with approximate, short stem-bases; on the lower side with numerous, thin, branching roots about 10 Cm. long; dull yellowish-brown, internally whitish; the wood-rays of the rhizome longest on the lower side; odor aromatic, camphoraceous; taste warm, bitterish, and camphoraceous. The roots of *Aristolochia reticulata* are coarser, longer, and less interlaced than those of *Aristolochia serpentaria*." *U. S.* They are also straighter. The color, which in the recent root is yellowish, becomes brown by time; that of the powder is grayish. Examined microscopically (see cut), the rhizome is seen to have only a moderately thick bark, composed chiefly of small-celled liber tissue; the woody tissue is formed of reticulated or pitted vessels and long prosenchymatous cells; the medulla is situated to the upper side of the centre, and has its cells large and thin-walled. The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, rendered turbid by the addition of water. Chevallier found in the root volatile oil, a yellow bitter principle, soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green, fragrant volatile oil, 28·5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144·5 of water. The active ingredients are probably the volatile oil and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia; alkaline solution of cupric tartrate shows, moreover, the presence of a glucose sugar. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the odor of the root. The volatile oil has been carefully investigated by J. C. Peacock (*A. J. P.*, 1891, 257). He found it to contain a terpene, $C_{10}H_{16}$, boiling at 157° C., of sp. gr. 0·865 (probably pinene); a compound ester boiling at 211° C., sp. gr. 0·9849, which on saponification yielded borneol, $C_{10}H_{18}O$, and a crystalline acid; a fraction boiling at from 239°–240° C., sp. gr. 0·9888, and of the composition $C_{18}H_{20}O$; and some green or bluish-green fluorescent oil in small quantity, which decomposes even when distilled under reduced pressure. The borneol ester constitutes about 60 per cent. of the oil. A principle called *aristolochine* has been investigated by Jul. Pohl (*Arch. f. Exper. Path. u. Pharm.*, xxix). He obtained it as a yellow crystalline mass, soluble in chloroform, ether, acetone, acetic anhydride, and alcohol, insoluble in petroleum ether, benzene, and carbon

disulphide, almost insoluble in cold water, slightly soluble in hot water. An ultimate analysis gives for its composition $C_{32}H_{22}NO_{13}$. O. Hesse obtained from the root of *Aristolochia argentina* an alkaloid to which he gives the name *aristolochine*, but has furnished no formula; a principle, *aristolin*, $C_{15}H_{28}O_3$; *physosterin palmitate*, in white scales, fusing at 82° C.; and a mixture of acids to which he gives the names *aristic acid*, $C_{18}H_{13}NO_7$, *aristidic acid*, $C_{17}H_{10}(CH_3)NO_7$, and *aristolic acid*, $C_{15}H_{13}NO_7$.*

The roots of *Spigelia marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts. (See *Spigelia*.) We have seen the young roots of *Polygala senega* mixed with serpentaria. Independently of their difference in odor and taste, they may be distinguished by being simple, and by a projecting line running from one end to the other of the root. Another adulteration has been detected by Mr. P. S. Milleman, of Chicago, who found in a parcel a large quantity of "golden seal" (*Hydrastis canadensis*). The rhizomes, with rootlets attached, were from a quarter of an inch to an inch in length, and about one-eighth of an inch in diameter. (*A. J. P.*, 1874, p. 516.)

Medical Properties and Uses. Serpentaria is a stimulant tonic, acting also as a diaphoretic or diuretic, according to the mode of its application. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. In *exanthematous diseases* in which the eruption is tardy or has receded and the grade of action is low, it is thought to be useful by promoting the cutaneous affection. It has been recommended in *intermittent fevers*, and may be serviceable as an adjunct to quinine. It is sometimes given in *dyspepsia*. The dose of fluid extract is from twenty minims to half a fluidrachm (1·25–1·9 C.c.). According to Pohl, aristolochine in sufficient dose produces in the higher animals violent irritation of the gastro-intestinal tract and of the kidneys, with death in coma from respiratory paralysis.

SEVUM. U.S. (Br.) Suet. [Mutton Suet.]

(SĒ'VŬM.)

"The internal fat of the abdomen of Ovis Aries, Linné (class, Mammalia; order, Ruminantia), purified by melting and straining. Suet should be kept in well-closed vessels impervious to fat. It should not be used after it has become rancid." *U. S.* "The internal Fat of the abdomen of the sheep, Ovis Aries, Linn., purified by melting and straining." *Br.*

Sevum Præparatum, *Br.;* Prepared Suet; Sebum, *P. G.;* Sebum Ovillum; Mutton-Suet; Suif, Graisse de Mouton, *Fr.;* Hammelstalg, Talg, *G.;* Grasso duro, *It.;* Sebo, *Sp.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water. Mutton suet is of a firmer consistence, and requires a higher temperature for its fusion, than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, palmitin, and olein, containing approximately 70 per cent. of stearin and palmitin and 30 per cent. of olein. These principles are described under the *Fixed Oils* (page 902). It is officially described as "a white, solid fat, nearly inodorous, and having a bland taste when fresh, but becoming rancid on prolonged exposure to the air. Insoluble in water or cold alcohol; soluble in 44 parts of boiling alcohol, in about 60 parts of ether, and slowly in 2 parts of benzin. From its solution in the latter, kept in a stoppered flask, it slowly separates in a crystalline form on standing. An alcoholic solution of Suet is neutral or has only a slightly acid reaction to litmus paper moistened with alcohol. Suet melts between 45° and 50° C. (113° and 122° F.), and congeals between 37° and 40° C. (98·6° and 104° F.)." *U. S.* "White, smooth, almost odorless; melting point between 112° and 120° F. (44·4° and 48·9° C.); commences to re-solidify at about 100° F. (37·8° C.). Freely soluble in *petroleum spirit*, slowly soluble in *benzol*, insoluble in cold *alcohol* (90 per cent.), slightly soluble in *ether* or boiling *alcohol* (90 per cent.)." *Br.* Mr. E. Dieterich examined a large number of samples of mutton and beef suet, and found that they were without exception acid and that neutral suet does not exist. The melting point of mutton suet is

* The resinous *aristinic acid* has been obtained from a number of species of the genus *Aristolochia*, notably by Walz from *A. clematitis*, by Chevallier from *A. serpentaria*, by Dymock and Warden from *A. indica*, by Hesse from *A. argentina*, by Hooper from *A. bracteata*. Hooper has also obtained a closely allied, if not identical, resinous acid from the aristolochiaceous plant *Bragantia Wallichii*, besides an alkaloid, which, under the name of *Alpam*, has long been used in Western India as an antidote to snake venom. The allied species, *Bragantia tomentosa*, of Blume, is said to be employed in Java as an emmenagogue.

between 48·5° and 50·5° C.; that of beef suet, between 47·5° and 48° C. The specific gravity of mutton suet lies between 0·937 and 0·952; that of beef suet, between 0·943 and 0·952. (*Arch. d. Pharm.*, 1887, 496.)

SINAPIS. Br. Mustard.

(SĮ-NĀ'PĬS.)

"The dried ripe seeds of Brassica nigra, Koch, and Brassica alba, Boiss., powdered and mixed." *Br.*

The British Pharmacopœia describes powdered mustard seed as "a greenish-yellow powder with a bitter pungent taste, inodorous when dry, but exhaling when moist a characteristic pungent odor. A cooled decoction is not rendered brown by a solution of *boric acid* (absence of turmeric), and should yield no characteristic reaction with the tests for starch."

SINAPIS ALBA. U. S. (Br.) White Mustard.

(SĮ-NĀ'PĬS ĂL'BĄ.)

"The seed of Brassica alba (Linné), Hooker filius et Thompson (nat. ord. Cruciferæ)." *U. S.* "The dried ripe seeds of Brassica alba, Boiss." *Br.*

Sinapis Albæ Semina, *Br.;* White Mustard Seeds; Semen Erucæ; Yellow Mustard Seed; Moutarde blanche, *Fr.;* Weisser Senf, *G.*

SINAPIS NIGRA. U. S. (Br.) Black Mustard.

(SĮ-NĀ'PĬS NĪ'GRĄ.)

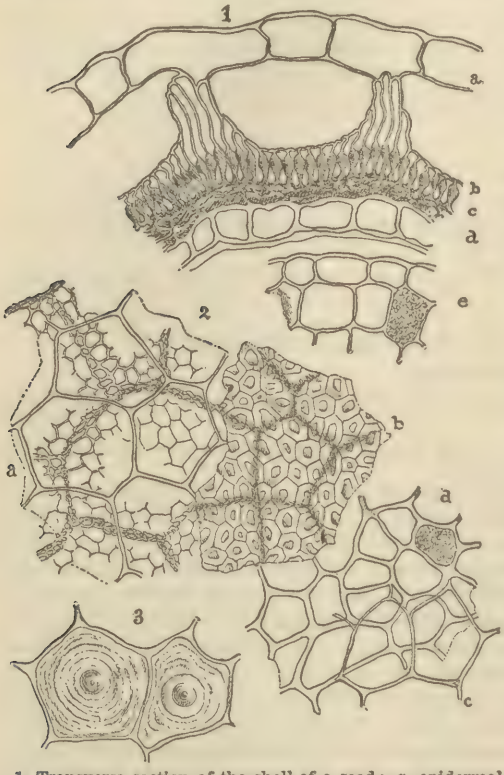
"The seed of Brassica nigra (Linné), Koch (nat. ord. Cruciferæ)." *U. S.* "The dried ripe seeds of Brassica nigra, Koch." *Br.*

Sinapis Nigræ Semina, *Br.;* Black Mustard Seeds; Semen Sinapis, *P. G.;* Moutarde noire (grise), Moutarde, *Fr.;* Senfsamen, Schwarzer Senf, *G.;* Senapa, *It.;* Mostaza, *Sp.*

Linnæus described two genera, Brassica and Sinapis, and subsequent botanists have greatly disagreed as to whether they should be considered distinct or not. Both Pharmacopœias at present follow Bentham and Hooker. Engler and Prantl and Britton and Brown, however, ascribe the origin of white mustard to *Sinapis alba*, L., and of black mustard to *Brassica nigra* (L.), Koch. The genus Sinapis differs from Brassica in that the pods of the former are terminated by a long, flat, sword-like beak, whereas in Brassica the beak is cylindrical or conical.

Sinapis nigra. Linné. *Sp. Pl.* (1753) 668.—*Brassica nigra.* Koch, in *Roehl. Deutschl. Fl.* (1833) 713. Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed, those higher on the stem are smooth, and less lobed; and the uppermost are entire, narrow, smooth, and dependent. The flowers are small, yellow, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, and furnished with a slender beak; seeds numerous, dark brown.

Sinapis alba. Linné. *Sp. Pl.* (1753) 668.—*Brassica alba.* Boiss. *Voy. Espag.* (1839–45) 39. The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.



Both plants are natives of Europe and cultivated in our gardens; and *S. nigra*, L., has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the pharmacies, both whole and in the state of very fine powder as prepared by the manufacturers for the table.* The latter is sometimes mixed with spice and ground into a smooth paste with water in a mill resembling a paint-mill, and then is known as *French mustard.*

The *Brassica juncea*, Coss. (*Sinapis juncea*, L.), is extensively grown in India, and its seeds

* The seeds of *Brassica iberifolia*, according to Prof. O. Harz, are sometimes sold as true white mustard seed. He examined some obtained from Bavaria, which had been returned by customers to the dealers on account of their bitter and disagreeable taste. He furnishes characteristic microscopical tests for distinguishing the false from the true mustard seed. His statement, however, that powdered white mustard seed when mixed with water is odorless, and that the false gives off a strong odor of essential oil of mustard, would seem to be a good reason for preferring the false seed. (*P. J. Tr.*, 1887, 478.)

are largely exported to Europe. The same plant is also cultivated in Southern Russia. The seeds afford a very fine yellow mustard flour, and, according to Paul Birkenwald, yield 1·67 parts per hundred of volatile oil, against 1·89 parts per hundred of the true black mustard seed. (*Schweiz. Wochenschr. f. Pharm.*, 1888.)

Black mustard seeds are officially described as "about 1 Mm. in diameter, almost globular, with a circular hilum; testa blackish-brown or grayish-brown, finely pitted, hard; embryo oily with a curved radicle, and two cotyledons, one folded over the other; free from starch; inodorous when dry, but when triturated with water, of a pungent, penetrating, irritating odor; taste pungent and acrid." *White mustard seeds* are much larger, of a yellowish color and less pungent taste. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard*, or simply *mustard*, and is prepared by crushing and pounding the seeds and then sifting them, the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. It is often adulterated with wheat flour colored by turmeric, to which red pepper is added to render the mixture sufficiently hot. The skin of white mustard seeds contains a mucilaginous substance which is extracted by boiling water. When bruised or powdered, both kinds impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, called *oil of mustard*, of a greenish-yellow color, little smell, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard consists of the glycerin compounds of stearic, oleic, and *erucic* or *brassic* acid, $C_{22}H_{42}O_2$, a homologue of oleic acid. Small quantities of *behenic* acid, $C_{22}H_{44}O_2$, also occur in oil of black mustard. This fixed oil is a yellow non-drying oil of from 0·915 to 0·920 sp. gr. at 15° C., solidifying at from —12° to —16°. It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odor in the seeds when bruised in a dry state, and their pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amygdala Amara*); and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. The composition and peculiar decompositions of the volatile oil of black mustard have already been described. (See *Oleum Sinapis Volatile.*)

1. Transverse section of the shell of a seed: *a*, epidermal layer with cells empty; *b*, connecting layer; *c*, layer of pigment-cells; *d*, parenchymatous cells; *e*, embryo. 2. Fragment of seed from a surface point of view; parts as in 1. 3. Cells from the epidermal layer, full of mucilage.

A principle was extracted by Dr. Will from white mustard seed, with the aid of alcohol. It has been named *sinalbin*, and has the formula $C_{30}H_{44}N_2S_2O_{16}$. It is decomposed, after the analogy of sinigrin (potassium myronate), into acrinyl sulphocyanate, C_8H_7NSO, sinapine bisulphate, $C_{16}H_{25}NSO_9$, and sugar, $C_6H_{12}O_6$, an albuminoid substance being formed at the same time. "The acrinyl sulphocyanate (C_8H_7NSO) is a very active principle, oily, insoluble in water, not volatile. It may be obtained by causing ether to act on the product of the decomposition of sinalbin. Treated by an alkali and then neutralized by an acid, it colors ferric chloride red." (*Journ. de Pharm.*, Avril, 1872, 327.)

The following analyses of mustard seeds and mustard flour are by Piesse and Stansell (*Analyst*, 1880, p. 161):

	White Mustard, whole seeds.		White Mustard, ground.		Brown Mustard, whole seeds.	Brown Mustard, ground.

Prof. J. U. Lloyd has proposed standards for black and white mustard seed, mainly directed towards limiting the proportion of starch; the latter is not a constituent of ripe mustard seed, but commercial mustard nearly always contains starch, due to starch-bearing seeds accidentally present in the mustard seed, or to fraudulent admixture. (*A. J. P.*, 1898, 433.)

Medical Properties and Uses. Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in *dyspepsia*, and in other complaints attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful (15·5 Gm.) once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The powder, commonly called simply mustard, in the quantity of from one to two teaspoonfuls (3·9–7·8 Gm.), is an efficient and prompt stimulant emetic, especially valuable in *narcotic poisoning*. As a condiment mustard acts as a stimulant to the gastric mucous membrane, and by virtue of this stimulant action it will sometimes relieve obstinate *hiccough*. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible and the degree of pain can afford no criterion of the sufficiency of the action. The volatile oil is powerfully rubefacient, and capable of producing speedy vesication, but certainly is less controllable than is the mustard poultice. For external application as a rubefacient, 30 drops of the oil may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. (See *Linimentum Sinapis Compositum*.) To form a *sinapism* it has been recommended to mix 20 drops of the volatile oil with 3·5 drachms of glycerin and 5 drachms of starch. It has been given internally in *colic*, two drops being incorporated with a six-ounce mixture, and half a fluidounce (15 C.c.) given for a dose. In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odor is perceptible in the blood, and it is said to impart the smell of horse-radish to the urine. A *spirit of mustard* may be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit.

SODIUM. Br. Sodium.

(SŌ'DI-ŬM.)

"The metal sodium as met with in commerce. It should be preserved in well-stoppered bottles under mineral naphtha." *Br.*

Sodium, *Fr.;* Natrium, Natronmetall, *G.;* Sodio, *It., Sp.*

Sodium is a peculiar metal, the hydrate of which is known as the alkali soda. It was dis-

covered by Sir H. Davy in 1807, who obtained it in small quantity by decomposing the alkali by the agency of galvanic electricity. Sodium was formerly prepared on a large scale by igniting an intimate mixture of dry sodium carbonate, coal, and chalk. The amount of metal obtained by this method is, however, not over 40 per cent. of the theoretical result. A much improved process was next brought out by Castner (*Journ. Soc. Chem. Indus.*, 1887, 174), in which an iron carbide, or a mixture of fine iron and coke, is used to reduce the caustic soda, according to the reaction $6NaOH + FeC_2 = 2Na_2CO_3 + 6H + Fe + 2Na$. The reduction of the sodium hydrate takes place at a temperature of about 800° C., and is carried out in steel crucibles, each of which holds 5·6 kilos of sodium hydrate and 1·97 kilos of carbide. The product of the reaction consists of about 4·85 kilos of sodium carbonate and 0·933 kilo of metallic sodium. This latter collects in a receiver connected with the top of the crucible, while the sodium carbonate is dissolved out from the residue and is causticized preparatory to being used again. This process in turn has been replaced by the electrolytic processes. The most successful of these is that of Castner, who uses an electrolyte of fused caustic soda in an iron pot or crucible with an anode of iron and a cathode of copper. The sodium is reduced at a comparatively low temperature, and is ladled from the vessel into moulds. The process is carried out at present on a large scale by the Niagara Electro-Chemical Co., and at Oldbury, England, and several places in Germany. By this electrical process the price of metallic sodium has been reduced to fifty cents per pound.

Sodium is a soft, malleable, ductile solid, of a silver-white color. It possesses the metallic lustre in a high degree, when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0·97, and its fusing point 95·6° C. (204° F.). Its chemical affinities resemble those of potassium, but are less energetic. Like potassium, it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on warm water it inflames. In both cases the water is decomposed, hydrogen is liberated, and sodium hydrate generated. Like potassium, if exposed with a bright surface to the air, it undergoes a slow combustion, which renders it luminous in the dark. It combines with oxygen to form the monoxide, Na_2O, and a peroxide, Na_2O_2. This latter oxide is always formed when the metal is burned in the open air. "A soft metal, rapidly oxidizing in the air, but showing a bright metallic surface when freshly cut. It violently attacks water or alcohol (90 per cent.), with evolution of hydrogen, little or no insoluble matter remaining. It imparts an intense yellow color to flame. Each gramme very cautiously added to water affords a solution which should require for neutralization at least 42·6 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

Sodium is a constituent of a number of important medicinal preparations, and is briefly described in this place as an introduction to these compounds. Its monoxide only is salifiable, and reacts with water to form the alkali soda, which, united to acids, gives rise to a numerous class of compounds, called sodium salts. These are characterized by communicating to the blowpipe flame a rich yellow color, and by not being precipitable by any reagent except potassium metantimoniate. Sodium monoxide consists of two atoms of sodium and one atom of oxygen. This reacts with water to form sodium hydrate (caustic soda), $Na_2O + H_2O = (NaOH)_2$. The dioxide (or peroxide), Na_2O_2, is now manufactured on a large scale from the metal, and used as a substitute for hydrogen peroxide in bleaching processes. It forms a canary-yellow powder, which decomposes rapidly in the presence of moisture.

The official combinations containing sodium are caustic soda, sodium chloride, the solutions of soda and chlorinated soda, sodium acetate, arsenate, benzoate, bicarbonate, bisulphite, borate, bromide, carbonate, chlorate, hypophosphite, hyposulphite, iodide, nitrate, nitrite, phosphate, pyrophosphate, salicylate, sulphate, sulphite, and sulphocarbolate, and potassium and sodium tartrate. The description of some of these combinations will immediately follow; and the remainder are commented on under their respective titles.

SODA. U. S. (Br.) Soda. [Sodium Hydrate. Sodium Hydroxide. Caustic Soda.]

NaOH; 39·96. (SŌ'DA.) NaOH; 40.

"Soda should be kept in well-stoppered bottles made of hard glass." *U. S.*

Sodium Hydroxide. *Br.* (Appendix), Soda Caustica; Caustic Soda, Hydrate of Soda; Natrum Causticum, s. Hydricum; Soude caustique, *Fr.*; Natron, Aetznatron, *G.*

"Take of Solution of Soda *two pints.* Boil down the solution rapidly, in a silver or clean iron vessel, until there remains a fluid of oily consistence, a drop of which when removed on a

warmed glass rod solidifies on cooling. Pour the fluid on a clean silver or iron plate, or into moulds, and, as soon as it has solidified, break it in pieces, and preserve it in stoppered green glass bottles." *Br.* 1885.

The Solution of Soda, being a solution of the caustic alkali, yields it on evaporation in the solid state. Metallic vessels are used in consequence of the chemical action of soda on earthenware or porcelain, and the product is directed to be kept in green glass bottles because these resist its action better than those of white glass. Soda is usually poured into cylindrical moulds to harden, or allowed to solidify in mass, and broken into irregular fragments.

"The sodium hydroxide, sodium hydrate, or 'caustic soda,' of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It affords the reactions characteristic of sodium. It usually contains as impurities alumina, carbonates, chlorides, phosphates, silicates, and sulphates. A clear solution of caustic soda may be used, instead of a solution of *Purified Sodium Hydroxide*, in all analytical operations in which the foregoing impurities would not vitiate the result.

"*Purified Sodium Hydroxide* may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is *Purified Sodium Hydroxide.* It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina.

"*Pure Sodium Hydroxide* may be prepared by the interaction of pure barium hydroxide and sodium sulphate, or by the interaction of pure sodium and water. A solution of Pure Sodium Hydroxide is required only in testing for small quantities of aluminium." *Br.* 1898, *Appendix.*

Soda is made commonly now on a large scale by simply modifying the Leblanc process (see *Sodii Carbonas*), so that more coal is added in the black-ash fusion, when carbonate is reduced to hydrate with the liberation of carbon monoxide by the action of the quick-lime, the reactions being $CaCO_3 + C = CaO + 2CO$ and $Na_2CO_3 + CaO + H_2O = 2NaOH + CaCO_3$. It is also made as the corresponding compound caustic potash is, by the decomposition of sodium carbonate in solution by quick-lime. (See *Liquor Sodæ.*) It may also be purified from carbonate, and from lime salts and other impurities, as the potassa is purified by treatment with alcohol, which dissolves the alkali, but leaves the salts insoluble. (See *Sodii Carbonas*, page 1241.) Chemically pure caustic soda can be made with commercial success from metallic sodium. The sodium is oxidized in water, using small pieces in succession, and keeping the temperature from rising too high. Caustic soda so obtained is free from sodium chloride and sulphate, and from alumina, silica, and ferric oxide. (*A. J. P.*, xlii. 50.) Klas Lindroth obtains a soda containing a mere trace of carbonate and chloride by evaporating the solution of impure soda until it has a sp. gr. of 1·375, and allowing it to crystallize at a temperature of 17° F. (*A. J. P.*, xliv. 106.) The manufacture of caustic soda in the United States has developed very greatly within the last few years, it being manufactured in connection with soda ash at the works of the Solvay Process Co., of Syracuse, New York, and Detroit, Michigan, and the Michigan Alkali Co., at Wyandotte, Michigan, and electrolytically at Niagara Falls by the Matthiessen Alkali Co. The importations of caustic soda are therefore decreasing, and will probably soon cease entirely.

It is officially described as "dry, white, translucent pencils, or fused masses, showing a crystalline fracture, odorless, and having an acrid and caustic taste. Great caution is necessary in tasting and handling it, as it rapidly destroys organic tissues. Exposed to the air, it rapidly deliquesces, absorbs carbon dioxide, and becomes covered with a dry coating of carbonate. Soluble in 1·7 parts of water at 15° C. (59° F.), and in 0·8 part of boiling water; very soluble in alcohol. When heated to about 525° C. (977° F.), Soda melts to a clear, oily liquid, and at a bright red heat it is slowly volatilized unchanged. When introduced into a non-luminous flame, it imparts to it an intense, yellow color. A solution of Soda, even when greatly diluted, gives a strongly alkaline reaction with litmus paper. The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of *organic matter*), and, after being acidulated with acetic acid, separate portions of it should yield no precipitate on the addition of platinic chloride test-solution, or sodium cobaltic nitrite test-solution, or excess of tartaric acid test-solution (limit of *potassium*). If 1 Gm. of Soda be dissolved in 10 C.c. of water and the solution slightly supersaturated with acetic acid, 10 C.c. of the solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *copper*, *lead*, etc.), nor by the subsequent addition of ammonia water

in slight excess (absence of *iron*, *aluminum*, etc.). The remainder of the acidulated solution should not be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). If a solution of 1·2 Gm. of Soda in 10 C.c. of water be slightly supersaturated with nitric acid, then 0·5 C.c. of decinormal silver nitrate volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If to a solution of 2·5 Gm. of Soda in 10 C.c. of water, strongly supersaturated with hydrochloric acid, 0·1 C.c. of barium chloride test-solution be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If 0·7 Gm. of Soda be dissolved in 1·5 C.c. of water, and the solution added to 10 C.c. of alcohol, not more than a slight, white precipitate should occur within 10 minutes (limit of *silicate*, etc.). After boiling this alcoholic solution with 5 C.c. of calcium hydrate test-solution and filtering, not the slightest effervescence should take place on adding the filtrate to an excess of diluted hydrochloric acid (limit of *carbonate*). If 0·2 Gm. of Soda be dissolved in 2 C.c. of water and carefully mixed with 5 C.c. of pure sulphuric acid and 3 drops of indigo test-solution, the blue color should not be entirely discharged (limit of *nitrate*). To neutralize 0·4 Gm. of Soda should require not less than 9 C.c. of normal sulphuric acid (each C.c. corresponding to 10 per cent. of pure sodium hydrate), phenolphtalein being used as indicator." *U. S.*

As prepared by the Br. 1885 process, caustic soda is in grayish-white fragments, opaque, brittle, and extremely corrosive. It is deliquescent, very soluble in water, soluble in alcohol, and possessed of all the alkaline properties of potassa, from which it differs in imparting a yellow color to flame, and in not giving in solution a yellow precipitate with platinic chloride or a crystalline precipitate with tartaric acid in excess. When heated it melts, and at an intense heat evaporates. Though deliquescent, like potassa, it does not, like that alkali, become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbonic acid of the air, potassa forms a deliquescent and soda an efflorescent salt. It is apt to contain 20 or 25 per cent. of water and impurities originating from the sodium carbonate used in preparing the solution from which it is made. The official volumetric assay permits the presence of 10 per cent. of impurities. (See *Potassa*.) If the solution be colored brown by hydrogen or ammonium sulphide, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept. It is used externally as a caustic in the same manner as potassa, when cast into sticks. It has the advantage of being less deliquescent, and is probably milder.* It may be used also for making the solution of soda extemporaneously. (See *Liquor Sodæ*.) For the general effects of soda upon the system, see *Sodii Carbonas*.

SODII ACETAS. U. S. Sodium Acetate.

$NaC_2H_3O_2.3H_2O$; 135·74. (SŌ′DI-Ī Ą-CĒ′TĂS.) $NaC_2H_3O_2.3H_2O$; 136.

"Sodium Acetate should be kept in well-stoppered bottles." *U. S.*

Acetate of Soda; Natrum Aceticum, *P. G.*; Acetas Sodicus (Natricus), Terra Foliata Tartari Crystallisata, Terra Foliata Tartari; Acétate de Soude, *Fr.*; Essigsaures Natron, *G.*; Acetato di Soda, *It.*

Sodium acetate may be easily prepared by adding crystals of sodium carbonate to acetic acid until it is neutralized, filtering, concentrating the solution, and crystallizing. It is prepared in the large way in the manufacture of crude pyroligneous acid, for the purpose of being decomposed, so as to yield the official acetic acid, by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have been given under *Acidum Aceticum*.

Properties. It is officially described as in "colorless, transparent, monoclinic prisms, or a granular, crystalline powder, odorless, and having a cooling, saline taste. Efflorescent in warm, dry air. Soluble, at 15° C. (59° F.), in 1·4 parts of water, and in 30 parts of alcohol; in 0·5 part of boiling water, and in 2 parts of boiling alcohol. When heated to 60° C. (140° F.), the salt begins to liquefy. At 123° C. (253·4° F.), it becomes dry and anhydrous; at 315° C.

* *London Paste.* The formula used at the London Throat Hospital for preparing this caustic is as follows. Take of caustic soda and unslaked lime equal parts. Reduce to a fine powder in a warm mortar, and mix intimately. Keep in well-closed bottles, and when required for use take as much as is sufficient. It is recommended for destroying enlarged tonsils or the elongated uvula, where treatment with the "guillotine" or scissors is objected to. This preparation resembles the Vienna Paste, but is preferable in consequence of its being less liable to spread beyond the limits of application. Soda being used instead of potash, and water in place of alcohol, the operation is much less painful. (*N. R.*, Aug. 1878.)

(599° F.), it is decomposed, with evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intense, yellow color, gives an alkaline reaction with litmus paper, and effervesces with acids. The aqueous solution (1 in 20) of the salt colors litmus paper or test-solution blue, but does not redden phenolphtalein test-solution, unless carbonate be present. If 5 C.c. of the aqueous solution be heated with 1 C.c. of sulphuric acid and 0·5 C.c. of alcohol, acetic ether will be formed, recognizable by its odor. On the addition of a few drops of ferric chloride test-solution, the solution assumes a deep-red color, and, when boiled, yields a brown precipitate. If a non-luminous flame be colored by the introduction of the salt, and viewed through a blue glass, the yellow color should entirely disappear, no red color taking its place (absence of *potassium*). If to 5 C.c. of the aqueous solution (1 in 20), slightly acidulated with acetic acid, an equal volume of hydrogen sulphide test-solution be added, no color or turbidity should appear, either at once (absence of *arsenic*, *lead*, *zinc*, etc.), or after adding ammonia water in slight excess (absence of *iron*, etc.). The aqueous solution, acidulated with acetic acid, should not be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). If a solution of 1 Gm. of the salt in 50 C.c. of water be slightly acidulated with nitric acid, then 0·5 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If to a solution of 2 Gm. of the salt in 10 C.c. of water, acidulated with hydrochloric acid, 0·1 C.c. of barium chloride test-solution be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If 1·36 Gm. of Sodium Acetate be completely decomposed at a red heat, and the residue dissolved in water, it should require, for complete neutralization, 10 C.c. of normal sulphuric acid (corresponding to 100 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* Sodium acetate, when crystallized, consists of one acetic acid radical, one atom of sodium, and 3 molecules of water.

Medical Properties and Uses. Sodium acetate is diuretic, but is very rarely used as a medicine. The dose is from twenty grains to two drachms (1·3–7·8 Gm.). It is employed principally to yield acetic acid by the action of sulphuric acid. In prescribing this salt, the fact, first noticed by M. Violette, should not be forgotten, that a mixture of equal parts of it and potassium nitrate, if heated, explodes with great violence. (*N. R.*, April, 1873.)

SODII ARSENAS. U. S., Br. Sodium Arsenate.

$Na_2HAsO_4.7H_2O$; 311·46. (SŌ′DI-Ī ĂR′SĒ-NĂS.) $Na_2HAsO_4.7H_2O$; 311·9.

"Sodium Arsenate should be kept in well-stoppered bottles." *U. S.* "The anhydrous salt, di-sodium hydrogen arsenate, Na_2HAsO_4, obtained by exposing to a temperature of 300° F. (148·9° C.) crystallized sodium arsenate, which may be prepared by treating with water the product of the fusion of arsenious anhydride with sodium nitrate and sodium carbonate." *Br.*

Natrum Arsenicum, Arsenias Natricus (Sodicus); Sodium Arseniate; Arseniate of Soda; Arséniate de Soude, *Fr.*; Arsensaures Natron, *G.*

In the United States Pharmacopœia the crystallized salt is official, while the anhydrous salt is the only one recognized in the British authority.

The process for this salt was first made official by the Br. Pharmacopœia of 1864, and by the U. S. Pharmacopœia of 1870.* In the process, the arsenous acid is converted into arsenic acid at the expense of the nitric acid of the sodium nitrate, and then combines with the soda of both salts, carbonic acid and nitrous fumes being given off. The reaction seems to be as follows:

$$As_2O_3 + 2NaNO_3 + Na_2CO_3 + H_2O = (Na_2HAsO_4)_2 + N_2O_3 + CO_2.$$

According to Mr. Higgins, the gases emitted in this process contain more or less arsenic,—an inconvenience which may be avoided by first dissolving the arsenous acid in a solution of caustic soda, and then adding the nitrate. The calcination should be performed in a reverberatory furnace. The gases which escape up the chimney are now free from arsenic, and consist only of ammonia and nitrous vapors. (*Journ. de Pharm.*, 4e sér., ii. 177.)

* "Take of Arsenious Acid, in fine powder, *two troyounces;* Nitrate of Sodium, in fine powder, *eight hundred and sixteen grains;* Dried Carbonate of Sodium, in fine powder, *five hundred and twenty-eight grains;* Distilled Water, boiling hot, *half a pint.* Having mixed the powders thoroughly, put the mixture into a large clay crucible, and cover with the lid. Expose it to a full red heat until effervescence has ceased, and complete fusion has taken place. Pour the fused salt on a porcelain slab, and, as soon as it has solidified, and while it is still warm, put it into the hot water, and stir until it is dissolved. Filter the solution, and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering paper, keep them in a well-stoppered bottle." *U. S.* 1870.

Properties. Sodium arsenate is in "colorless, transparent, monoclinic prisms, odorless, and having a mild, alkaline taste (the salt is very poisonous). Efflorescent in dry air, and somewhat deliquescent in moist air. Soluble in 4 parts of water at 15° C. (59° F.), and very soluble in boiling water; very sparingly soluble in cold, but soluble in 60 parts of boiling alcohol. When gently heated, the salt loses 5 molecules of water (28·8 per cent.), and is converted into a white powder. At 148° C. (298·4° F.) the rest of the water of crystallization is lost, the salt fuses, and at a red heat is converted into pyroarsenate. It imparts an intense, yellow color to a non-luminous flame. The aqueous solution (1 in 20) of the salt yields a white precipitate with barium chloride test-solution, or with calcium chloride test-solution, and a dark red precipitate with silver nitrate test-solution, all of which precipitates are soluble in nitric acid. If 0·5 C.c. of the aqueous solution (1 in 20) be mixed with 2 C.c. of hydrochloric acid, and a drop of this mixture be placed upon a bright piece of copper-foil, upon applying a gentle heat, a dark steel-gray film will be deposited from the drop upon the copper. If to 2 C.c. of the aqueous solution (1 in 20) 5 C.c. of silver nitrate decinormal volumetric solution be added, and the precipitate redissolved by excess of ammonia water, no black precipitate of reduced silver should appear on boiling (absence of *arsenite*). If to 5 C.c. of the aqueous solution 1 C.c. of ammonium sulphide test-solution be added, no turbidity or coloration should appear (absence of *lead*, *copper*, *iron*, etc.)." *U. S.* "A white powder, soluble in 6 parts of *water*, and yielding an alkaline solution. It is only slightly soluble in cold or boiling *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of arsenates. A solution of 1 gramme of Sodium Arsenate with 1 of *glacial acetic acid*, in 50 cubic centimetres of *water*, should require 2·03 grammes of *lead acetate* for complete precipitation. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, calcium, magnesium, potassium, ammonium, carbonates, chlorides, nitrates, or sulphates. It should not lose weight on being heated to 300° F. (148·9° C.) (absence of hydrous sodium arsenate)." *Br.*

Anhydrous sodium arsenate has the composition Na_2HAsO_4; in crystals it sometimes contains 12 mols. of water, equal to 53·73 per cent. of its weight. According to the official formula, this salt also crystallizes with 7 mols. of water, or 40·39 per cent. "The latter salt loses 40·38 per cent. of its weight when dried at 300° F. (148·9° C.), becoming anhydrous. An aqueous solution of 12·4 grains of anhydrous arseniate of sodium, acidulated with acetic acid, requires not less than 34 grains of acetate of lead for complete precipitation." *Br.* 1885. If the temperature of a solution of the salt be kept at 30° C. (86° F.), crystals will be deposited which contain 4 mols. of water. J. Lefort examined 10 different samples of the salt, obtained from as many different sources, and found their water of crystallization to vary from 44·05 to 57·45 per cent. (*Journ. de Pharm. et de Chim.*, 1880, 487.)

In medical properties this salt agrees with the other preparations of arsenic (see *Acidum Arsenosum*), and may be employed for the same purposes. The dose of the crystallized salt is stated at from one-twelfth to one-third of a grain (0·005–0·02 Gm.), that of the anhydrous salt from one-fortieth to one-tenth of a grain (0·0016–0·006 Gm.); but it is generally prescribed in the form of solution. (See *Liquor Sodii Arsenatis.*) Arsenic has been used to a considerable extent hypodermically in the treatment of *chorea* and other nervous diseases. According to the clinical studies of H. N. Moyer, sodium arsenate is preferable to Fowler's solution for this purpose, as being more uniform in composition and less irritating. The drug should be kept for use in hypodermic tablets. Dr. Moyer gives from one-tenth to one-twentieth of a grain in from ten to fifteen minims of distilled water.

Pearson's arsenical solution is an aqueous solution of sodium arsenate, and much weaker than the official solution. (See PART II., *National Formulary.*) This preparation is considerably used on the continent of Europe in the form of bath, for which it is preferred to arsenous acid or the arsenites. The arsenical bath has been especially commended by M. Guéneau de Mussy in *nodose rheumatism*, or *rheumatic gout:* dose for a bath, from half a drachm to two or three drachms (1·95–7·8 or 11·65 Gm.). (*Ann. de Thérap.*, 1865, 270.)

SODII BENZOAS. U. S., Br. Sodium Benzoate.

$NaC_7H_5O_2$; 143·71. (SŌ'DI-Ī BĔN'ZŌ-ĂS.) $NaC_7H_5O_2$; 144.

"Sodium benzoate, C_6H_5COONa, may be obtained by neutralizing benzoic acid with sodium carbonate." *Br.*

Sodæ Benzoas; Benzoate of Soda.

Sodium benzoate is easily made by adding benzoic acid to a concentrated hot solution of sodium carbonate or bicarbonate until effervescence ceases, and allowing the solution to cool and

crystallize. R. Rother, in order to avoid annoyances in the effervescence, mixes four ounces of benzoic acid and two and three-quarters ounces of sodium bicarbonate in an evaporating-dish with from two to four fluidounces of alcohol; when a uniform mixture is produced, from three to six fluidounces of water are added, heat applied gently, and the powder granulated.

Properties. It is officially described as "a white, amorphous powder, odorless, or having a faint odor of benzoin, and a sweetish, astringent taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 1·8 parts of water, and in 45 parts of alcohol; in 1·3 parts of boiling water, and in 20 parts of boiling alcohol. When heated, the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. If a few drops of ferric chloride test-solution be added to an aqueous solution of the salt, a flesh-colored precipitate will be deposited. If 5 C.c. of diluted nitric acid be added to a solution of 1 Gm. of the salt in 10 C.c. of water, a white precipitate of benzoic acid will be produced, which, after being thoroughly washed, should conform to the tests of purity given under *Acidum Benzoicum*. The filtrate from the precipitated benzoic acid should not be rendered turbid by silver nitrate test-solution (absence of *chloride*), nor by barium chloride test-solution (absence of *sulphate*). Five C.c. of the aqueous solution (1 in 20) should not give a precipitate with 0·5 C.c. of sodium cobaltic nitrite test-solution (limit of *potassium*). If to 5 C.c. of the aqueous solution (1 in 20) an equal volume of hydrogen sulphide test-solution be added, no coloration or turbidity should be perceptible either before or after the addition of 1 C.c. of ammonia water (absence of *lead*, *iron*, etc.). If 2 Gm. of Sodium Benzoate be ignited in a porcelain capsule until most of the carbonaceous matter is destroyed, and the residue be then dissolved in 20 C.c. of water, it should require for complete neutralization not less than 13·9 C.c. of normal sulphuric acid (corresponding to at least 99·8 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "Soluble in less than 2 parts of cold *water*, in 24 parts of cold *alcohol* (90 per cent.), and in 12 of boiling *alcohol* (90 per cent.). An aqueous solution has a faintly alkaline reaction, and gives a yellowish or flesh-colored precipitate when mixed with *test-solution of ferric chloride*. A strong aqueous solution, to which a little *diluted hydrochloric acid* is added, affords a crystalline precipitate of benzoic acid. Each gramme of the salt, when heated, melts, emitting an odor of benzoin, then chars, and finally leaves a residue which affords the reactions characteristic of sodium, and, when dissolved in *water*, requires for neutralization from 6·8 to 6·9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, iron, calcium, magnesium, potassium, ammonium, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates." *Br.*

Medical Properties. This salt was suggested as long ago as 1857, by MM. Socquet and Bonjean, as a remedy in *gout* and *rheumatism*, and is certainly valuable in *lithæmia* and *lithæmic gravel* for the purpose of aiding in the elimination of uric acid. It has also been highly commended in *puerperal fever*, and in *tuberculosis*.* (*Brit. Med. Journ.*, ii. 1879, 498, 982.) From one to two drachms (3·9–7·8 Gm.) may be given, in divided doses, during the day.

SODII BICARBONAS. U. S., Br. Sodium Bicarbonate.

$NaHCO_3$; 83·85. (SŌ′DI-Ī BI-CĂR′BO-NĂS.) $NaHCO_3$; 84.

"Sodium Bicarbonate, $NaHCO_3$, may be obtained by exposing crystals of sodium carbonate to carbonic anhydride, or by the interaction of sodium chloride and ammonium bicarbonate." *Br.*

Natrum Bicarbonicum, *P. G.;* Natrum Carbonicum Acidulum; Bicarbonas Sodicus; Bicarbonate of Soda, Sodium Hydrocarbonate, Acid Sodium Carbonate; Bicarbonate de Soude, Sel digestive de Vichy, *Fr.;* Doppeltkohlensaures Natron, *G.*

Two kinds of sodium bicarbonate were formerly official,—one, which is known by the title of this article, and which, to comply with the test, must not have more than one per cent. of impurity, and the other, "commercial bicarbonate," which must contain at least 95 per cent. of pure bicarbonate. To obtain a salt which would comply with the official test it was necessary to purify the commercial salt, and the process of the U. S. Pharm. 1870 will be found as serviceable as any to accomplish this purpose.† The U. S. Pharm. 1890 recognizes only

* *Sodium Boro-benzoate.* According to Mr. Thos. S. Wiegand, this salt may be made by adding benzoic acid to a hot solution of borax to saturation and evaporating to dryness; or by making an aqueous solution of three ounces of borax and another with four ounces of sodium benzoate, mixing, and evaporating to dryness, the yield is about six ounces. The dose is from twelve to fifteen grains. (*A. J. P.*, 1884, p. 615.)

† "Take of Commercial Bicarbonate of Sodium, in powder, *sixty-four troyounces;* Distilled Water, *six pints*. Introduce the powder into a suitable conical glass percolator, cover it with a piece of wet muslin, and pour the Water

the purer salt, having dismissed *Sodii Bicarbonas Venalis.* Sodium bicarbonate must now contain 98·6 per cent. of the pure salt.

Immense quantities of sodium bicarbonate were formerly imported from Great Britain, but the importation has fallen off, and is only trifling at present, amounting in 1897 to only 965,669 lbs., of a value of $13,982. It is now made of excellent quality by the Pennsylvania Salt Manufacturing Co., at Natrona, Pa., using cryolite as raw material, and by the Solvay Process Co., of Geddes, near Syracuse, N. Y., using the ammonia-soda process. (See *Sodii Carbonas.*) In the Pharmacopœia of 1886 a process for making sodium bicarbonate was given, but it has since been abandoned, as the salt can be made much more economically on the large scale. The process consists in treating crystallized sodium carbonate, contained in suitable chambers, with carbon dioxide gas until the carbonate has taken up another molecule of carbon dioxide. It is formed by the union of neutral carbonate, Na_2CO_3, with carbon dioxide gas, CO_2, in the presence of water, H_2O, according to the following reaction: $Na_2CO_3 + CO_2 + H_2O = (HNaCO_3)_2$, two molecules of the bicarbonate being generated. The necessary water is obtained through the liberation of the water of crystallization of the carbonate; in fact, provision has to be made for the escape of the excess by placing the crystals upon perforated bottoms.

We are informed that sodium bicarbonate is also prepared in breweries, in the same manner as potassium bicarbonate or saleratus, by placing the carbonate in suitable vessels over the fermenting beer in the vats, so as to be constantly immersed in an atmosphere of carbonic acid. It is sold under the same name as the analogous salt of potassa, but is usually distinguished as *soda sal aëratus.*

Properties. The purified bicarbonate is officially described as "a white, opaque powder, odorless, and having a cooling, mildly alkaline taste. Permanent in dry, but slowly decomposed in moist air. Soluble in 11·3 parts of water at 15° C. (59° F.); above that temperature the solution loses carbon dioxide, and at a boiling heat the salt is entirely converted into normal carbonate. Insoluble in alcohol and in ether. When heated, the salt is decomposed into normal carbonate, water, and carbon dioxide, and finally, at 100° C. (212° F.), loses about 36·3 per cent. of its weight. At a bright red heat it melts. To a non-luminous flame it imparts an intense, yellow color. The solution, when freshly prepared with cold, distilled water, without shaking, gives a very faint alkaline reaction with litmus paper. The alkalinity increases by standing, agitation, or increase of temperature. With acids the solution effervesces strongly. If 1 Gm. of the salt be dissolved in 19 C.c. of water, it should yield a perfectly clear and colorless solution, leaving no residue. If 5 C.c. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride test-solution (absence of *sulphocyanate*). If 1 Gm. of the salt be dissolved in 3 C.c. of acetic acid, it should yield no precipitate within an hour after being mixed with 0·5 C.c. of sodium cobaltic nitrite test-solution (limit of *potassium*). If 0·6 Gm. of the salt be dissolved, without agitation, in 10 C.c. of cold water, and 0·1 C.c. of normal sulphuric acid added, no red color should appear upon the addition of 2 drops of phenolphtalein test-solution (limit of *normal carbonate*). If 5 C.c. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the solution should not be rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, either at once (absence of *arsenic*, etc.), or after the addition of ammonia water in slight excess (absence of *iron*, *aluminum*, etc.). Five C.c. of the aqueous solution, acidulated with acetic acid, should not be rendered turbid by 0·5 C.c. of ammonium oxalate test-solution (absence of *calcium*). If 1·2 Gm. of Sodium Bicarbonate be dissolved in 10 C.c. of diluted nitric acid, then 0·5 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 2·5 Gm. of the salt be dissolved in 11 C.c. of diluted hydrochloric acid, then 0·1 C.c. of nitric acid and 0·1 C.c. of barium chloride test-solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*, *sulphite*, and *hyposulphite*). If Sodium Bicarbonate be heated in a test-tube, no *ammoniacal* vapor should be emitted. To neutralize 0·85 Gm. of Sodium Bicarbonate should require not less than 10 C.c. of normal sulphuric acid (corresponding to at least 98·6 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "In

gradually upon it. When the liquid has ceased to drop, or when the washings cease to precipitate a solution of sulphate of magnesium, remove the Bicarbonate of Sodium from the percolator, and dry it on bibulous paper, in a warm place." *U. S.* 1870.

powder or small opaque monoclinic crystals, white, of a saline taste, soluble in 11 parts of cold *water*. It affords the reactions characteristic of sodium and of bicarbonates. Each gramme should require for neutralization from 11·8 to 11·9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, calcium, magnesium, potassium, sulphites, or thiosulphates, and only the slightest characteristic reactions with the tests for chlorides, sulphates, or ammonium. A solution of the salt in cold *water* gives a whitish precipitate, becoming brownish-red on standing, with *test-solution of mercuric chloride* (distinction from sodium carbonate). The addition of *test-solution of ferric chloride* to the aqueous solution acidulated with *hydrochloric acid* should cause no red coloration (absence of thiocyanates). 20 parts of Sodium Bicarbonate are neutralized by 16·7 parts of Citric Acid, and by 17·8 parts of Tartaric Acid." *Br.* The salt furnished by the manufacturers very rarely comes up to the requirements of the Pharmacopœias. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with magnesium sulphate, and by a solution in 40 parts of water affording, without agitation, an orange-colored or reddish-brown precipitate with corrosive sublimate. The pure bicarbonate is not precipitated by platinic chloride, nor, when treated with nitric acid in excess, by barium chloride or silver nitrate. The non-action of these tests shows the absence of salts of potassa, and of sulphates and chlorides. For Wenzell's method of testing sodium bicarbonate, see *Proc. A. P. A.*, 1894, 277.

When the solution is exposed to heat, the salt gradually parts with carbonic acid, and, at the temperature of 100° C. (212° F.), is converted into sesquicarbonate. At a red heat the second equivalent of carbonic acid is expelled, and the anhydrous carbonate is left. More or less sodium carbonate is always present in the commercial bicarbonate. Its presence may be known by a decided alkaline taste and reaction, and by a cold solution of the salt yielding a precipitate with magnesium sulphate. The pure bicarbonate is not precipitated by platinic chloride. The incompatibles of this salt are the same as those of the carbonate, except magnesium sulphate in the cold, which decomposes the carbonate, but not the bicarbonate.

Sodium hyposulphite has been detected in small amount in European sodium bicarbonate by E. Mylius, who supersaturated the suspected bicarbonate in solution with sulphuric acid, and added a little pure zinc, when the odor of hydrogen sulphide was produced. A slight trace of arsenic was also discovered in the sodium bicarbonate. (*Archiv d. Pharm.*, 1886, p. 598.) Prof. F. B. Power subsequently examined samples of American bicarbonate, and found them all free from hyposulphite and arsenic: he detected, however, traces of chlorides, ammonia, and monocarbonate in the commercial salt. (*Pharm. Rundschau*, 1887, p. 35.) Mr. E. Kuhlmann recommends rosolic acid as the best test for detecting monocarbonate: if a small fragment be placed in a solution of sodium bicarbonate, the liquid remains perfectly colorless even after a quarter of an hour if the salt be pure; but if it contain from one to four per cent. of monocarbonate a rose-red color will be produced after a few moments, and *immediately* in the presence of larger quantities, rapidly changing them to purple-red. (*Arch. d. Pharm.*, 1887, p. 72.)

Medical Properties. This salt has the general medical properties of the carbonate, but, from its mild taste and its less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in *calculous cases* characterized by excess of uric acid. The continued use of the carbonate in these cases is liable to induce phosphatic deposit after the removal of the uric acid. According to D'Arcet, who made the observation at the springs of Vichy, this objection does not apply to the bicarbonate, especially when taken in carbonic acid water; for this salt, by its superabundant acid, has the power of maintaining the phosphates in solution even after the alkali has caused the uric acid to disappear. The same remark is applicable to potassium bicarbonate. Sodium bicarbonate has been given in *infantile croup*, with apparent advantage in promoting the expulsion of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. Dr. Lemaire has proposed it as an antiphlogistic remedy in the treatment of *pneumonia*, *membranous angina*, and *croup*, supposing it to act on the principle of removing from the blood the excess of fibrin which exists in that liquid in inflammation. Its utility in membranous angina has been confirmed by M. Marchal (de Calvi). According to M. Jeannel, the use of sodium bicarbonate lessens the sugar in the urine of diabetic patients. The dose for an adult is from ten grains to a drachm (0·65–3·9 Gm.), and is taken most conveniently in a glass of carbonic acid water. When given in angina, fifteen grains (1 Gm.) may be administered every half-hour in a tablespoonful of water.

SODII BISULPHIS. U. S. Sodium Bisulphite.

$NaHSO_3$; 103·86. (SŌ′DI-Ī BĪ-SŬL′PHIS.) $NaHSO_3$; 104.

"Sodium Bisulphite should be kept in a cool place, in small, well-stoppered bottles, filled as full as possible." *U. S.*

Sodium bisulphite is prepared by thoroughly saturating a concentrated solution of sodium carbonate or bicarbonate with sulphurous acid gas, and collecting the crystals which form upon the cooling of the liquid. As found in commerce, it usually contains sodium hyposulphite and sulphate, is not reliable, and will not respond to the official tests: even when kept in well-stopped bottles it will readily lose its crystalline character, and the quantity of sulphurous acid gradually diminishes. The bisulphite, under the technical name of *leucogen*, is largely used in many industries. It serves as bleaching agent in washing wool, and is also used in the steeping of grain, and in preserving meats and vegetable juices, because of its reducing and anti-fermentative character.

Properties. It is officially described as in "opaque, prismatic crystals, or a granular powder, exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble, at 15° C. (59° F.), in 4 parts of water, and in 72 parts of alcohol; in about 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an acid reaction with litmus paper. On the addition of hydrochloric or sulphuric acid, the aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate test-solution and held over the escaping gas. If 1·2 Gm. of Sodium Bisulphite be dissolved in 10 C.c. of diluted nitric acid, and the solution heated sufficiently to expel the gases, then 0·5 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 2·5 Gm. of Sodium Bisulphite be dissolved in 11 C.c. of diluted hydrochloric acid with the aid of sufficient heat to expel the sulphur dioxide, the solution should not be turbid (absence of *hyposulphite*). After adding to it 0·15 C.c. of barium chloride test-solution, and removing the precipitate, if any, by filtration, a portion of the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If to 5 C.c. of the preceding filtrate an equal volume of hydrogen sulphide test-solution be added, no turbidity or coloration should occur (absence of *arsenic*, etc.). If 0·26 Gm. of Sodium Bisulphite be dissolved in 20 C.c. of water, recently boiled to expel air, and a little starch test-solution be added, at least 45 C.c. of iodine decinormal volumetric solution should be required to produce a permanent blue tint after agitation (corresponding to at least 90 per cent. of pure Sodium Bisulphite)." *U. S.*

Medical Properties. The medical properties are those of the sulphites generally. (See *Sodii Sulphis.*)

SODII BORAS. U. S. (Br.) Sodium Borate. [Borax.]

$Na_2B_4O_7.10H_2O$; 380·92. (SŌ′DI-Ī BŌ′RĂS.) $Na_2B_4O_7.10H_2O$; 382.

"This salt, sodium pyroborate, $Na_2B_4O_7.10H_2O$, occurs native. It is also made artificially by neutralizing native boric acid with sodium carbonate, or by boiling native calcium borate with solution of sodium carbonate." *Br.*

Borax, *Br., P.G.;* Sodæ Biboras, Biborate of Soda, Sodium Biborate, Sodium Pyroborate; Natrum Biboricum (Biboracicum), Boras Sodicus; Borate de Soude, Borax, *Fr.;* Borax, Borsaures Natron, *G.;* Boracе, *It.;* Borax, *Sp.;* Boorak, *Arab.*

Borax was known to the ancients; but its chemical nature was first ascertained by Geoffroy in 1732. It exists native, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds, associated with calcium borate, in the district of Iquique, in the republic of Ecuador. This mineral (*boronatrocalcite*), which has become an article of commerce, and is considerably used as a substitute for borax, contains, according to T. L. Phipson, 34 per cent. of water, 11·95 of soda, 14·45 of lime, 34·71 of boric acid, 1·34 of chlorine, 1·10 of sulphuric acid, 0·60 of silica, and 2 of sand, and may be considered as a compound essentially of one mol. of crystallized sodium borate and two mols. of calcium borate, with two mols. of water. It is said also to contain usually some iodine and bromine. (*G. Sims.*)

Borax has long been known to occur in certain lakes of Thibet and Persia, from which it was obtained by spontaneous evaporation. It constitutes the impure borax called in commerce *tincal.*

An abundant source of borax has been developed within the limits of the United States. The existence of a borax lake in California was first made known by Dr. J. A. Veatch, who visited it in September, 1856, and, upon examining its waters, found borax among its constituents. The borax lake is a small offset of a large sheet of water, called Clear Lake, which is situated in the midst of a volcanic region, about 36 miles from the Pacific, and about 100 miles north of San Francisco. The smaller lake is separated from the larger by a low ridge of volcanic materials loosely massed together. It is of variable dimensions according to the season, being sometimes dry, at other times filled with water to the extent of about a mile in length and half a mile in breadth. In September, 1863, the water, being analyzed by Dr. G. E. Moore, was found to contain in a gallon 2401·56 grains of solid matter, of which about one-half was common salt, one-quarter sodium carbonate, and the remainder chiefly sodium borate, equivalent to 535·08 grains of the crystallized biborate to the gallon. The borax, being the least soluble of the saline constituents, from time to time, as the water becomes saturated, crystallizes out, and is deposited at the bottom of the lake, where it has accumulated in large quantities. The crystals of borax, from the minutest speck up to a diameter of two or three inches, intermixed with blue mud, form a layer at the bottom of the lake of variable thickness,—18 inches in one place that was examined. This deposit forms an apparently inexhaustible supply of borax, for as fast as removed in one place it is deposited in another by crystallization from the water, which, supplied from the volcanic regions around, promises to continue furnishing the borax for an indefinite period. Already the lake has supplied large quantities of borax to commerce. Iron coffer-dams are sunk to the bottom of the lake, the water pumped out, and the mixed mud and crystals removed. The crystals are picked out, and the earth, which is strongly impregnated with borax, is lixiviated, and the solution thus obtained evaporated in boilers till crystals form. In 1868 operations practically ceased at Borax Lake, but were continued at the neighboring Hachinhama Lake until 1873. At present the supply of American borax comes from the more easily worked deposits in the sandy deserts about Death Valley, southeast of Pyramid Lake, in Nevada, in the Slate Range district, San Bernardino Co., and the Saline Valley, Inyo Co., California. In order to reduce as much as possible the cost of transportation, the boraxes of the Pacific coast are made usually of high quality, and the so-called "boracic acid glass," one pound of which is equal to three pounds of ordinary borax, is prepared. For an interesting description of the Slate Range district, see *Chem. News*, 1886, 245. The most important deposits now (1899) being worked in California are the *colemanite* (*calcium borate*) deposits twelve miles northeast of Daggett in the Mojave Desert. The formation (one hundred feet or more in width) has been traced for fully ten miles. The colemanite is readily dissolved by sodium carbonate solution, when the borax crystallizes out. The total production of borax in the United States for 1897 was 21,422,000 lbs., or 9717 metric tons.

The world's production of borax and boric acid minerals for 1896 was as follows: United States (refined borax), 6649 metric tons; Chili (ulexite, etc.), 8486 metric tons; Germany (boracite), 184 tons; Italy (crude boric acid), 2616 tons; Peru (ulexite in 1895), 4000 tons; Turkey (pandermite), 11,375 tons.

Preparation of Artificial Borax. Large quantities of borax are now made for the European market by the direct combination of *native boric acid* with soda. The acid is found abundantly in the crater of Vulcano, one of the Lipari Islands, but principally in a volcanic region of Tuscany occupying a space of ten or twelve miles. Within this region are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating-pans, heated by the natural vapor, where it receives sufficient concentration to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid, thus obtained, contains, on an average, 84 per cent. of boric acid, the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The seven works in the neighborhood of Castelnuovo in Tuscany, belonging to Count Larderel, were pro-

ducing, in 1878, over three millions of kilogrammes. Vulcano yielded 4000 kilogrammes of boric acid yearly. The crude acid is converted into borax by dissolving it to saturation in a solution of sodium carbonate, heated by steam; and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The impure crystals thus obtained are refined by dissolving them in water heated by steam, adding sodium carbonate to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France. According to Dr. Veatch, boric acid exists in the sea-water on the coast of California.

Another method of neutralizing the Italian boric acid is practised in England. Instead of combining the acid and alkali in solution, the manufacturer mixes the acid in a solid state with a proper proportion of soda ash, and exposes the mixture to the heat of a reverberatory furnace, provision being made for the collection of a large quantity of ammonia, which is always present in the crude acid and escapes during the process. The remaining operations are similar to those performed in the preparation of sodium carbonate from the cake. (*A. J. P.*, 1867, p. 339.)

Properties. Borax is a white salt, occurring in "colorless, transparent, monoclinic prisms, or a white powder, inodorous, and having a sweetish, alkaline taste. Slightly efflorescent in warm, dry air. Soluble in 16 parts of water at 15° C. (59° F.), and in 0·5 part of boiling water; insoluble in alcohol. At 80° C. (176° F.) it is soluble in 1 part of glycerin. When heated, the salt at first loses part of its water, then melts, and, when further heated, swells up and forms a white, porous mass. At a red heat it loses all its water of crystallization (47·14 per cent.), and fuses to a colorless glass. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution (1 in 20) colors red litmus paper blue, and yellow turmeric paper reddish-brown. After being acidulated with hydrochloric acid, the solution colors blue litmus paper red; yellow turmeric paper remains unchanged at first, but, on drying, becomes brownish-red, and this color is temporarily changed to bluish-black by moistening with ammonia water. If a drop of the solution of the salt in glycerin be held in the flame, a transient bright green color will appear. If a slight excess of sulphuric acid be added to a hot, saturated, aqueous solution of the salt, shining, scaly crystals of boric acid will separate on cooling, which impart a green color to the flame of alcohol. With 19 C.c. of water, 1 Gm. of the salt should yield a perfectly clear and colorless solution, leaving no residue. The aqueous solution (1 in 20) should not effervesce with acids (absence of *carbonate*). It should not be rendered turbid by ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.); nor, after being acidulated with hydrochloric acid, by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *lead*, etc.). When acidulated with acetic acid, the solution should not be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). The aqueous solution (1 in 20) should not be rendered turbid by magnesia mixture (absence of *phosphate*). If 0·48 Gm. of the salt be dissolved in 15 C.c. of water, then 1 C.c. of diluted nitric acid and 0·2 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 2·5 Gm. of the salt be dissolved in 50 C.c. of water, then 10 C.c. of diluted hydrochloric acid and 0·1 C.c. of barium chloride test-solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If 1 Gm. of the salt be dissolved in 20 C.c. of diluted sulphuric acid by the aid of heat, and 3 drops of indigo test-solution be added, the blue color should not be discharged (absence of *nitrate*)." *U. S.* "Transparent colorless crystals, sometimes slightly effloresced, with a weak alkaline reaction; insoluble in *alcohol* (90 per cent.), soluble in 25 times its weight of cold, and in half its weight of boiling *water*. It dissolves in its own weight of *glycerin*. It turns *turmeric paper* brown. It colors flame intensely yellow. A hot saturated solution, when acidulated with any of the mineral acids, lets fall, as it cools, a scaly crystalline deposit of boric acid, the solution of which in *alcohol* (90 per cent.) burns with a green flame. Each gramme dissolved in 200 cubic centimetres of *water* should require for neutralization 5·2 cubic centimetres of the *volumetric solution of sulphuric acid*, using *methyl orange* as the indicator." *Br.* Above a red heat it melts into a limpid liquid, which, after cooling, concretes into a transparent solid, called *glass of borax*, much used as a flux in assays with the blowpipe. Borax has been found in the English market adulterated to the extent of 20 per cent. with sodium phosphate. This may be detected by exposing the suspected borax to the heat of a

drying-room for a few hours, when the phosphate, if present, will effloresce, and may be picked out. Commercial borax is used as a flux in metallurgical operations; as the basis of the enamel so much applied to iron utensils, glazed brick, and much china, earthen-ware, and tiling; in the laundry with starch to impart a gloss to linen; by the meat-packers of the United States (1000 tons yearly) as an antiseptic; and very largely in soaps and toilet preparations and in detergent powders.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar*, which is sometimes used in medicine. This preparation attracts moisture from the air, and is soluble in its own weight of cold and half its weight of boiling water. (See *Potassii Bitartras.*) R. F. Fairthorne states that borax is more soluble in water if sugar has been added to it. (*A. J. P.*, March, 1881.) Soluble cream of tartar may be made by substituting boric acid for the borax. *Boric acid soluble cream of tartar* was directed by the French Codex of 1837, and was made by the following formula. Four hundred parts of cream of tartar and 100 of the acid are dissolved in a silver basin, at the boiling temperature, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, powdered, and kept in well-stopped bottles. This form of soluble cream of tartar is more soluble than that made with borax. According to M. E. Robiquet, in order to obtain soluble cream of tartar, made with boric acid, of good quality, it is necessary to use a large quantity of water, and to boil for a long time. By proceeding thus, the boric acid undergoes a molecular modification, equivalent to a change from the crystallized to the vitreous condition, and a preparation readily and totally soluble in cold water is insured. The product should not be powdered, but kept in large grains. (*Journ. de Pharm.*, xxi. 197.) Borax is incompatible with the alkaloids; in warm solution it decomposes chloral.

Composition. Borax has the formula $Na_2B_4O_7 + 10H_2O$. It ordinarily crystallizes in monoclinic prisms, and contains ten mols. of water (*prismatic borax*); but a variety of the salt exists which crystallizes in octahedrons, and contains only five mols. of water (*octahedral borax*). The latter is obtained in the artificial production of borax by crystallizing from a concentrated solution at a temperature between 60° and 80° C. (140° and 176° F.). When a solution of borax is evaporated at 100° C. (212° F.), the salt is left as a transparent, amorphous, brittle mass, containing four mols. of water. (Schweitzer.)*

Boric acid may be obtained artificially by decomposing a hot saturated solution of borax with sulphuric acid, which unites with the soda to form sodium sulphate and sets free the acid. As thus obtained it is in white, shining, scaly crystals, characterized by the property of imparting a light-green color to the flame of burning alcohol. Boric acid has the formula H_3BO_3, and is now official. (See *Acidum Boricum.*) *Boron* is a non-metallic element, which, like carbon, exists in three allotropic states, called amorphous, graphitoidal, and crystallized boron, representing severally charcoal, graphite, and diamond. Crystallized boron is very brilliant, and of different colors, from garnet-red to a nearly colorless honey-yellow. Its density is 2·68, and its hardness very great. Wöhler and Deville distinguished three varieties of crystals, containing from 2 to 4 per cent. of carbon; and one specimen, in addition to carbon, about 7 per cent. of aluminum. The hardest variety was as hard as diamond. (See *Chem. Gaz.*, 1857.)

Medical Properties. The actions of borax and of boric acid upon the animal system are identical. The effects of the drug are, however, very feeble, Cyon having found that in daily doses of three drachms borax exerts no perceptible influence upon the dog. Nevertheless, in sufficient amount it is a depressing poison, having an influence upon the heart as well as upon the spinal centres, and a number of instances of poisoning from it have been reported. The symptoms have varied somewhat, but in most if not all of the cases there have been great depression of spirits, fall of bodily temperature, a very feeble pulse,—rapid or slow,—and an erythematous eruption accompanied with much swelling of the parts, and especially affecting the lower extremities, and followed by exfoliation; nausea, violent vomiting, and hiccough have been present in some cases; ecchymoses have been noted; the mind usually remains clear

* *Sodium borate* (neutral) or *sodium tetraborate* may be made by adding boric acid to a hot concentrated aqueous solution of sodium diborate or borax until it has a neutral reaction; the crystals which separate (sodium borate) have been erroneously described under the name sodium tetraborate. They are transparent, fragile, and glassy; it is found in commerce in glass-like masses. It is soluble in cold water, but more soluble (70 per cent.) in hot water.

until late in the poisoning, but death has been preceded by coma, with disturbances of the respiration, and involuntary discharges. The continued use of borax has produced "*borism*," which is characterized by gastric irritation, a peculiar absence of fatty matter and of moisture from the skin, and various skin eruptions, especially eczema, reddish papules with squamous desquamating borders, seborrhœic acne, and scarlatiniform plaques.

Borax has been used internally in *dysmenorrhœa*, and as an oxytocic for a supposed specific influence upon the uterus, and has also been employed in a *uric acid diathesis*. Again, it has been highly commended in *epilepsy*, but in a careful test made on a large scale in the epileptic wards of the Philadelphia Hospital by Dr. H. C. Wood it was found to have little or no influence on that disorder. The internal dose is from thirty to forty grains (1·95–2·6 Gm.).

Borax is a germicide of moderate power. According to the experiments of Sternberg, it is more efficient in preventing putrefaction than in destroying the organisms of disease. Dr. Walb found that a five-per-cent solution of it would keep fibrin perfectly fresh for nineteen days. It has been used to a considerable extent in antiseptic surgery, and, being free, or nearly so, from irritating properties, may be applied in powder or in strong solution to *wounds*, *ulcers*, *abscesses*, etc. Wounds dressed in a dry manner with a lint which has been prepared by previously wetting with a hot saturated solution of borax and drying, are said to do extremely well. Its chief value in practical medicine grows out of its peculiar detergent, mildly stimulant, or alterative action upon mucous membranes. In *aphthous ulceration*, *diphtheria*, and other *inflammations of the mouth*, crystals of it may be allowed to dissolve slowly in the mouth. Professor Bouchut has highly recommended, in *infantile diarrhœa*, enemas made by dissolving from two to five drachms of borax in two fluidounces of water. Washing out the bladder with a saturated solution of boric acid or borax is most efficacious in *subacute* and *chronic cystitis*. The same solution has also been found very useful in *inflammations of the urethra and vagina*, especially when there is pruritic irritation, and even in *scaly diseases of the skin*. A solution in distilled water, from five to ten grains to an ounce, is often of great service in *conjunctivitis*. Borax should not be prescribed in dilute solution mixed with glycerin, as a reaction occurs, the liquid becoming acid to test-paper.

SODII BROMIDUM. U. S., Br. Sodium Bromide.

NaBr; 102·76. (SŌ'DI-Ī BRŌ'MI-DŬM.) NaBr; 102·8.

"Sodium Bromide, NaBr, may be prepared in the same manner as Potassium Bromide, sodium hydroxide being used in place of potassium hydroxide." *Br.*

"Sodium Bromide should be kept in well-stoppered bottles." *U. S.*

This salt contains a larger proportion of bromine than does potassium bromide, on account of the lower atomic weight of sodium, sodium bromide containing 77·62 per cent. of bromine, whilst potassium bromide contains 67·13 per cent. It is a trifle more soluble in water and alcohol. It may be made by the same process that is employed for potassium bromide, substituting sodium carbonate for potassium carbonate. According to M. Castelhaz, it is best made by transforming bromine into ammonium bromide, separating any iodine present as iodide by crystallization from the mother-waters, and decomposing the ammonium bromide with sodium carbonate. The solution should be evaporated by heating carefully. (*A. J. P.*, xlii. 509.)

Properties. It occurs in "colorless or white, cubical crystals, or a white, granular powder, odorless, and having a saline, slightly bitter taste. From air the salt attracts moisture without deliquescing. Soluble, at 15° C. (59° F.), in 1·2 parts of water, and in 13 parts of alcohol; in 0·5 part of boiling water, and in 11 parts of boiling alcohol. When heated to a bright red heat, the salt melts, and, at a somewhat higher temperature, slowly volatilizes without decomposition. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral, or at most very feebly alkaline, to litmus paper. If a few drops of chloroform be poured into 10 C.c. of the aqueous solution (1 in 20), then 1 C.c. of chlorine water added, and the mixture agitated, the liberated bromine will dissolve in the chloroform, imparting to it a yellow or brownish-yellow color, without a violet tint. The aqueous solution (1 in 20) should be clear and colorless, and should not be rendered turbid by sodium bitartrate test-solution, nor by sodium cobaltic nitrite test-solution (limit of *potassium*); nor by ammonium oxalate test-solution (absence of *calcium*); nor by barium chloride test-solution (absence of *sulphate*). If the aqueous solution be slightly acidulated with hydrochloric acid, it should not

be rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, either at once (absence of *arsenic*, *lead*, etc.), or after adding ammonia water in slight excess (absence of *iron*, *aluminum*, etc.). If diluted sulphuric acid be dropped upon some of the powdered salt, no yellow color should appear at once (absence of *bromate*). If 5 C.c. of the aqueous solution (1 in 20) be mixed with a few drops of starch test-solution, and then 0·5 C.c. of chlorine water added, no blue color should appear (absence of *iodine*). If 1 Gm. of the powdered salt be kept for twenty minutes at the temperature of 100° C. (212° F.), or slightly above it, it should not lose more than 0·03 Gm. in weight (limit of *moisture*). If 0·3 Gm. of the well-dried salt be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, it should not require more than 29·8 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to at least 97·29 per cent. of the pure salt)." *U. S.* "Soluble in less than 2 parts of *water*, and in 16 parts of *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of bromides. Each gramme of the dry salt dissolved in *water* should require for complete precipitation not less than 95·8 nor more than 97·8 cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, carbonates, cyanides, bromates, or iodates, and only the slightest reactions with the tests for chlorides, iodides, or sulphates. *Test-solution of ferric chloride* should not cause a red coloration in the aqueous solution (absence of thiocyanates)." *Br.*

Medical Properties. The medical properties of sodium bromide are similar to those of potassium bromide, except that the sodium salt is less powerful and much less depressant to the circulation. Dose, from one-half drachm to one drachm (1·95–3·9 Gm.).

SODII CARBONAS. U. S., Br. Sodium Carbonate.

$Na_2CO_3.10H_2O$; 285·45. (SŌ′DI-Ī CĂR′BO-NĂS.) $Na_2CO_3.10H_2O$; 143.

"Sodium Carbonate, $Na_2CO_3,10H_2O$, may be obtained from sodium chloride, either by interaction with ammonium bicarbonate and subsequent ignition, or by its conversion into sodium sulphate and the action of heat on a mixture of the sulphate with carbon and calcium carbonate." *Br.*

Carbonate of Soda, Sal Soda, Washing Soda; Natrum Carbonicum Crudum, *P. G.;* Carbonas Sodicus, Sal Sodæ; Carbonate de Soude, *Fr.;* Einfach Kohlensaures Natron, Kohlensaures Natron, Soda, *G.;* Carbonato di Soda, *It.;* Carbonato de Soda, *Sp.*

Before entering upon the consideration of sodium carbonate, we shall speak generally of the sources of the alkali soda. These may be divided into the natural and the artificial. The natural sources are the minerals of native soda, and certain marine plants which yield the alkali in their ashes; the artificial are certain salts which furnish it by chemical decomposition.

Native soda, sometimes called *natron*, is found chiefly in Hungary, Egypt, and South America, and exists in these countries either in the surface earth, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. The native soda from Egypt, called *trona*, is a *sesquicarbonate;* that from South America is less carbonated. Of these sources, the only one which retains any importance at the present day is Egyptian trona, of which some 5000 tons are annually shipped from Alexandria. Native soda, in the form of sesquicarbonate, has been found in a soda lake in the territory of the Nizam, in Hindostan. Dr. Barth, in his *Travels in Africa*, states that natron is largely collected on the shores of Lake Tchad, and in some other localities in Central Africa. A similar product exists abundantly in low places along the sea-coast of Arabia, near Aden. (R. Haines, *P. J. Tr.*, July, 1863.) Probably the most numerous and extensive natural soda deposits in the world exist in Southeastern Wyoming, in the counties of Albany, Carbon, and Natrona. The salts are the carbonate and sulphate, at times pure, and again as mixtures both hydrated and partly dehydrated. For a full account of these localities with analyses of different deposits, see *The Mineral Industry* for 1897, 612–616. New York, 1898.

Impure soda, derived from the ashes of plants growing on the surface or borders of the sea, is called barilla or kelp, according to the character of the plants incinerated. Barilla is obtained from several vegetables, principally belonging to the genera *Salsola*, *Salicornia*, and *Chenopodium*. In Spain, Sicily, and some other countries these plants are cultivated for the purpose of yielding soda by their combustion. When ripe, they are cut down, dried, and

burnt in heaps. The ashes form a semi-fused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and thrown into commerce. Kelp, called *varec* in France, is procured by the incineration of various kinds of sea-weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkneys and Hebrides, and the rocky coasts of Wales, Scotland, and Ireland, furnish large quantities of these weeds. The plants are fermented in heaps, then dried, and afterwards burnt to ashes in ovens roughly made of brick or stone and built in the ground. The alkali in the ashes melts, and forms the whole into a solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. About twenty-four tons of sea-weeds produce one ton of kelp. *Barilla*, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence on exposure. It possesses a peculiar odor and an alkaline taste. *Spanish barilla* contains from 25 to 40 per cent. of carbonated alkali, the residue being made up of sodium sulphate, sodium sulphide and chloride, calcium carbonate, alumina, silica, oxidized iron, and a small portion of charcoal which has escaped combustion. Before the introduction of artificial soda, barilla formed the source of the crystallized carbonate employed in medicine. At present it is principally used in the manufacture of soap. *Kelp* is in hard, vesicular masses, of a dark-gray, bluish, or greenish color, a sulphurous odor, and an acrid, caustic taste. It it still less pure than barilla, containing only from 5 to 8 per cent. of carbonated soda, the rest being made up of a large proportion of sodium and potassium sulphates, and potassium and sodium chlorides, a small quantity of sodium iodide, and insoluble and coloring matters. Large quantities of kelp were formerly manufactured in Great Britain and the neighboring islands, particularly the Orkneys; but the demand and production have generally fallen off since the introduction of artificial soda. At present kelp is used principally in the manufacture of iodine. (See *Iodum.*)

Artificial Soda. This is made from common salt by the older or Leblanc process in two steps: first, by converting the salt by sulphuric acid into sodium sulphate, and, secondly, by decomposing the sulphate by calcium carbonate and charcoal at a high temperature, so as to yield sodium carbonate. The chemical reactions may be summarized as follows: $2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$, $Na_2SO_4 + CaCO_3 + C_4 = Na_2CO_3 + CaS + (CO)_4$. The sulphate, first dried, is mixed with its own weight of ground limestone, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, which may be either stationary or, as is more general now, revolving on a horizontal axis. In this "black-ash furnace" the mixture fuses, and forms a black mass called *black ash*, *soda ball*, or *British barilla*. The coal, at the temperature employed, converts the sodium sulphate into sodium sulphide. This reacts with the limestone, so as to form calcium sulphide and sodium carbonate (Na_2S and $CaCo_3 = CaS$ and Na_2CO_3). Black ash contains from 36 to 45 per cent. of alkali, imperfectly carbonated on account of the high heat used, the remainder being principally calcium sulphide, caustic lime, sodium chloride, calcium sulphite, and coaly matter. It is next digested in warm water, which takes up the alkali and other soluble matters, and leaves the insoluble impurities, called *soda waste*, which is now largely utilized in the manufacture of sodium hyposulphite. The solution is evaporated to dryness, and the mass obtained is calcined with one-fourth of its weight of sawdust, in order to convert the alkali fully into carbonate, by means of the carbonic acid resulting from the combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. The alkali, in this stage of its purification, contains about 50 per cent. of sodium carbonate, and is called *soda-ash*. It is brought to the state of crystallized sodium carbonate by dissolving it in water, straining the solution, evaporating it to a pellicle, and setting it aside to crystallize. This process was invented in 1784 by Leblanc; and the first manufactory for producing it on a large scale was established in 1790, near Paris, by Leblanc and Dizé. The process is pursued on an immense scale in Great Britain, especially in Liverpool and Glasgow. Various modifications have been proposed, and in part carried into practice, which affect the Leblanc process more or less fundamentally. One of the most important of these is the Hargreaves-Robinson method of preparing "salt-cake" or sodium sulphate without the previous preparation of sulphuric acid. Sulphur dioxide (from the roasting of pyrites), atmospheric oxygen, and steam are made to act upon salt previously prepared in broken cakes or fragments. Sodium sulphate and hydrochloric acid are obtained. The use of sodium nitrate is dispensed with, the sulphate is purer than that of the old method, and the hydrochloric acid is more easily condensed. It requires, however, a more expensive plant. A troublesome side-product of the Leblanc process is the calcium sulphide or "alkali waste," and much ingenuity has been used in endeavoring to utilize

this and to recover the sulphur. The most successful sulphur recovery process thus far has been that of Chance, who decomposes the calcium sulphide by carbon dioxide, liberating H_2S. This is mixed with air and passed over a layer of ferric oxide, which at a low red heat causes the hydrogen to burn, liberating the sulphur, which may either be collected or burned to SO_2 for the lead-chamber process. It is asserted that 95 per cent. of the sulphur can be thus recovered.

The Gossage process, still more recently proposed, aims to avoid the formation of the "alkali waste" altogether, and to do away with the black-ash furnace. By heating the salt-cake with the necessary proportion of coal-slack the sodium sulphate is reduced to sodium sulphide. This is dissolved, allowed to settle, and the supernatant liquid, freed from silica and alumina, is conducted to towers, where it is treated with excess of carbon dioxide, whereby sodium bicarbonate and hydrogen sulphide are formed. The bicarbonate may be heated to change it into normal salt, while the carbon dioxide is utilized in decomposing fresh quantities of sulphide.

Within the last few decades a process has been put in practice which has given so much satisfaction in its results as to be likely to rival, if not to supersede, the hitherto unequalled process of Leblanc. It is designated the *ammonia-soda* process, and is based on the fact that when carbon dioxide is passed into a solution of common salt in aqueous ammonia a double decomposition occurs, and the slightly soluble sodium bicarbonate is precipitated: $NH_3 + CO_2 + NaCl + H_2O = HNaCO_3 + NH_4Cl$. From the mother-liquor containing the sal-ammoniac, if deemed advisable, the ammonia may be withdrawn by the action of lime, and serve in the renewal of the operation. The sodium bicarbonate is reduced by heat to the carbonate, and the carbonic acid thus obtained serves to convert the ammonia into the ammonium bicarbonate necessary in the proceeding. The waste product here is calcium chloride, which takes with it all the chlorine of the salt originally used. Therefore if the ammonia-soda process were to replace the Leblanc process, hydrochloric acid and chlorine would have to be made independently, and would become much dearer than at present. To obviate this objection to the ammonia-soda process and to produce hydrochloric acid as one product of the same process, the late Walter Weldon proposed to use magnesia instead of lime in the decomposing of the sal-ammoniac. This would leave magnesium chloride instead of calcium chloride. From the magnesium chloride the chlorine can be obtained as follows: $MgCl_2 + H_2O = 2HCl + MgO$. Steam will liberate hydrochloric acid from the magnesium chloride. This process is carried out practically at Salindres in France, although its economy is not definitely established.

A still more promising suggestion is that of the distinguished chemist Ludwig Mond, of Brunner, Mond & Co., who are the chief English manufacturers of ammonia-soda. He proposes to freeze out the ammonium chloride from the mother-liquors by artificial refrigeration, sublime it, and pass the vapor over magnesia, whereby the hydrochloric acid is retained in combination with the magnesia as magnesium chloride, while the ammonia passes on. The magnesium chloride is then heated in a current of air, when it is split up into chlorine and magnesia.

The reaction between ammonium bicarbonate and common salt, upon which the ammonia process was founded, was first discovered by Dyar and Hemming about 1838, but it was only in 1863 that Ernest Solvay, a Belgian chemist, made it a practical success. The advantages of this method are that the common salt is directly transformed into sodium carbonate, that in the precipitation sodium is the only metal thrown down, and that the preparation is therefore remarkably pure, that it is entirely exempt from the compounds of sulphur, that the amount of product is very large, that the apparatus used in the process is very simple, that there is a great saving of fuel and of labor, and, finally, that no unwholesome gases are diffused in the atmosphere, interfering with the health of the workmen and the community. MM. Schloesing and Rolland have observed that in the double decomposition between ammonium bicarbonate and sodium chloride a certain portion only—about two-thirds—undergoes the change. This is explained by M. Bauer, who finds that the reaction is limited by another in an inverse direction. Thus, if ammonium bicarbonate and sodium chloride yield sodium bicarbonate and ammonium chloride (hydrochlorate of ammonia), these, put together, inversely yield ammonium bicarbonate and sodium chloride. An equilibrium is thus established, and the mixture preserves a constant composition, at the point where the two reactions take place at the same time. (*Journ. de Pharm. et de Chim.*, Sept. 1874.) At present the ammonia-soda process is gaining rapidly upon the Leblanc process. It is stated that 75 per cent. of the total German soda production is now obtained by the ammonia-soda process, in France 60 per cent., and in Austria 47 per cent. In England, where the Leblanc process is most strongly entrenched and backed by the

resources of the "United Alkali Company," a combination of manufacturers with a paid-up capital of $42,000,000, it is also gaining, as shown by the following figures, showing the amount of salt decomposed in the Leblanc and ammonia-soda processes respectively:

	1894. Tons.	1895. Tons.	1896. Tons.
Leblanc process	434,298	408,173	360,929
Ammonia-soda process	361,603	428,614	431,577
Total production	795,901	836,787	792,506

The production of alkali—reckoned as 58° soda ash—in the United States amounted to 157,475 metric tons in 1896, and to 277,072 metric tons in 1897. The main producers were the Solvay Process Co. and the Michigan Alkali Co.

Another source of this carbonate has been discovered in *cryolite*, a mineral existing in great abundance on the coast of Greenland, and largely imported into this country by a manufacturing company which enjoys to a certain extent a monopoly of the mineral under the Danish authorities. Cryolite consists mainly of a double aluminum and sodium fluoride, containing in 100 parts 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with lime, whereby calcium fluoride is formed, while the sodium and aluminum combine to form a sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbonic acid under pressure through the solution; and the alumina, separated from the soda, becomes insoluble, and is deposited. (*A. J. P.*, Jan. 1868, p. 71.) Cryolite is also largely used in Denmark and Germany in the preparation of sodium carbonate and of alumina, the latter of which is employed in the manufacture of alum and aluminum.

Besides the preparation of sodium carbonate, cryolite is employed for other important purposes. Within recent years it has become quite important as a flux for the electrolytic production of aluminum by the Hall and similar processes. (See *Alumen.*) Its only known locality, at least in large amount, is Greenland, where it is found on the southwest coast, near Cape Farewell, existing in beds, of which one is said to be eighty feet thick and three hundred long. It is imported by the "Pennsylvania Salt Manufacturing Company" into Philadelphia in immense quantities. It is a handsome mineral, hard, brittle, and translucent, sometimes almost transparent, but generally of a frosty whiteness, which probably suggested its name of *cryolite* or *kryolite*, from the Greek *κρύος*, *frost*. Though homogeneous in great degree, it exhibits here and there in its substance dark spots, sometimes mere specks, sometimes of considerable size, which appear to be crystalline centres of substances mixed with it at the time of solidification, such as galena, ferric carbonate, copper and iron pyrites, etc.

The different kinds of impure sodium carbonate, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to have a ready method of determining the quantity of real carbonated alkali which they contain. The mode in which this is done, by means of an instrument called an alkalimeter, has been already explained. (See page 1088.) These various forms of carbonated soda are largely consumed in dyeing and bleaching, and in the manufacture of soap and glass. In reference to "the English commercial test," see *A. J. P.*, Sept. 1870, p. 447. The following are descriptions of the different grades of artificial soda, known under the names of British barilla, and soda-ash.

British barilla, so called to distinguish it from Spanish barilla, which has its source in the ashes of maritime plants, is a blackish-brown substance, becoming darker by exposure to the air. When broken it exhibits an imperfect metallic lustre, and a close striated texture. Its taste is alkaline and caustic. On exposure to a moist atmosphere it becomes covered with a yellow efflorescence, and quickly falls to powder, with disengagement of heat and hydrogen sulphide, at the same time increasing in weight by the absorption of carbonic acid and water.

Soda-ash is in white or gray compact masses, and contains about half its weight of foreign salts, consisting principally of sodium chloride and sodium sulphate.

Properties. The carbonate occurs in "colorless, monoclinic crystals, odorless, and having a strongly alkaline taste. In dry air the salt effloresces, and, if left exposed, soon loses about half of its water of crystallization (31·467 per cent. of its weight), and becomes a white powder. Soluble in 1·6 parts of water at 15° C. (59° F.), in 0·09 part at 38° C. (100·4° F.), and in 0·2 part of boiling water; insoluble in alcohol and in ether; soluble in 1·02 parts of glycerin. When heated to 32·5° C. (90·5° F.), the crystals fuse in their water of crystallization, and lose some water. At a higher temperature, the salt continues to lose water, until, at last, an anhy-

drous residue is left, corresponding to 37 per cent. of the weight of the crystals. At a bright red heat the anhydrous salt fuses. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an alkaline reaction with litmus paper, and effervesces strongly with acids. A 5-per-cent. aqueous solution of the salt should be perfectly clear and colorless, leaving no insoluble residue. If 5 C.c. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride test-solution (absence of *sulphocyanate*). If to 5 C.c. of the aqueous solution, slightly supersaturated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, no turbidity should be produced, either before or after the addition of ammonia water in slight excess (absence of *arsenic*, *lead*, *iron*, *aluminum*, etc.). If 5 C.c. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0·5 C.c. of ammonium oxalate test-solution should produce no turbidity (absence of *calcium*). If 5 C.c. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0·5 C.c. of sodium cobaltic nitrite test-solution should not render it turbid within one hour (limit of *potassium*). If 1·2 Gm. of the salt be dissolved in 10 C.c. of diluted nitric acid, then 0·5 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 2·5 Gm. of the salt be dissolved in 10 C.c. of diluted hydrochloric acid, then 0·1 C.c. of nitric acid and 0·1 C.c. of barium chloride test-solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*, *sulphite*, and *hyposulphite*). If the crystallized salt be heated in a test-tube, the vapor of *ammonia* should not be evolved. To neutralize 1 Gm. of anhydrous Sodium Carbonate (deprived of its water of crystallization by heat immediately before being weighed) should require not less than 18·7 C.c. of normal sulphuric acid (corresponding to not less than 98·9 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "In transparent colorless rhombic crystals, efflorescent, with a harsh taste and strong alkaline reaction, soluble in 2 parts of cold *water*. It should respond to the qualitative tests enumerated under 'Sodii Bicarbonas,' except that its aqueous solution gives an immediate brownish-red precipitate with *test-solution of mercuric chloride*. When heated it liquefies and then dries up, losing 62·93 per cent. of its weight. Each gramme of the crystallized salt should require for neutralization at least 6.9 cubic centimetres of the *volumetric solution of sulphuric acid*. 20 parts of Sodium Carbonate are neutralized by 9·8 parts of Citric Acid, and by 10·5 parts of Tartaric Acid." *Br.* This salt presents an anomaly in solubility, as ascertained by M. Henri Loewel: it is more soluble in water at 36·1° C. (97° F.) than at its boiling point. Sodium carbonate is insoluble in alcohol. The most usual impurities in it are sodium sulphate and common salt, which may be detected by converting it into a nitrate and testing separate portions of this severally with barium chloride and silver nitrate.* Common salt is seldom entirely absent, but good specimens are free from sodium sulphate. When badly prepared it is liable to contain sodium sulphide, which may be detected by the production of the smell of hydrogen sulphide upon dissolving the salt in water. Sodium carbonate is incompatible with acids, which decompose it with effervescence, acidulous salts, lime water, ammonium chloride, and earthy and metallic salts. When crystallized it contains ten mols. of water. It is thus perceived that this salt, when crystallized, contains nearly two-thirds of its weight of water; but the quantity actually present in it, as found in commerce, is variable, being dependent on the extent to which it may have undergone efflorescence. To obtain pure sodium carbonate for the purpose of a test, Dr. J. Lawrence Smith, of Louisville, Ky., recommends that sodium oxalate should be prepared from the common carbonate, and then decomposed by heat.†

* For a method of determining the precise quantity of the sulphate in a special case, see *Journ. de Pharm.*, Août, 1873, p. 124.

† Dr. Smith gives the following particular description of the method employed by him. 63 grammes of oxalic acid and 143 grammes of ordinary sodium carbonate are dissolved, with heat, in 200 cubic centimeters of distilled water; the solution is distilled, filtered if necessary, and, when it cools, the solution of oxalic acid, just hot enough to prevent crystallization, is added by degrees, with stirring. It is expected that the solution, when completed, shall have a slight alkaline reaction. Shortly after the operation is finished, the sodium oxalate will be in a great measure precipitated. The whole is then allowed to stand till completely cool; the supernatant liquid is decanted, a little distilled water added, and the lumps of crystals that may have formed are broken up by a stirrer, thrown on a six-inch filter over a Bunsen aspirator, washed with about half a liter of distilled water, and allowed to dry. The quantity of dry oxalate produced is 30 grammes. In this state it may be kept in a dry bottle till wanted for use in forming sodium carbonate. It is then projected, little by little, into a platinum capsule, over a good-sized Bunsen burner. After being strongly heated, the oxalate is changed by the decomposition of the oxalic acid into the carbonate, and, if

Medical Properties and Uses. Soda being the natural alkali of the blood and other liquids of the human organism, its influence upon that organism in disease is very slight. In the experiments of Gradeau the injection of 107 grains of sodium carbonate directly into the blood of a dog produced practically no symptoms, and in the studies of Dr. Münch upon the effect on the human system of the continuous exhibition for a few days of large amounts of soda the results were almost entirely negative. The chief influence of the salt is upon certain of the liquid excretions. Thus, the urine becomes distinctly alkaline, without, however, so far as we know, there being any distinct change in its general constituents. The experiments of Lewaschen prove that soda salts given to dogs with biliary fistula increase very markedly the liquidity of the bile and diminish the percentage of solids in it. These experiments are in accord with clinical experience, which shows that the alkaline sodium salts, given one to two hours after meals in full dose, are of decided value in the treatment of *gall-stones* and various affections associated with excessive acidity of the biliary secretion. On account of its having no general effect upon the system, soda and its carbonates are superior to potassium as simple alkaline remedies. When, therefore, it is desired to overcome *acidity of the stomach or intestines*, or to render acid urine alkaline, these preparations are very available; but they are not applicable in *gout*, *uric acid diathesis*, *rheumatism*, and occasionally in other diseases attended with *gastric acidity*, when it is desirable to bring about increased destruction of tissue and increased elimination of solids. Under these circumstances sodium salts are inferior to the potassium salts. Alkaline sodium salts are also employed with advantage, internally and externally, in *skin diseases*, especially those of a papulous and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. In recent *burns* without much destruction of the skin, the free application of a saturated solution will usually give immediate relief. Sodium carbonate is given in doses of from ten grains to half a drachm (0·65–1·95 Gm.), either in powder or dissolved in some bitter infusion. When taken in an overdose, it acts as a corrosive poison. The best antidotes are the fixed oils, acetic acid, and lemon-juice.

SODII CARBONAS EXSICCATUS. U. S., Br. Dried Sodium Carbonate.

(SŌ′DI-Ī CĂR′BO-NĂS ĔX-SIC-CĀ′TŬS.)

"Nearly anhydrous sodium carbonate, Na_2CO_3, which is obtained by heating Sodium Carbonate until it loses nearly 63 per cent. of its weight." *Br.*

Natrum Carbonicum Siccum, *P. G.;* Dried Carbonate of Soda; Carbonate de Soude sec, *Fr.;* Getrocknete Soda, *G.*

"Sodium Carbonate, *two hundred grammes* [or 7 ounces av., 24 grains]. To make *one hundred grammes* [or 3 ounces av., 231 grains]. Break the crystals into small fragments, and allow them to effloresce for several days in warm air, at a temperature not exceeding 25° C. (77° F.), until they are completely disintegrated; then dry the white powder at a temperature of about 45° C. (113° F.), until its weight is reduced to *one hundred grammes* [or 3 ounces av., 231 grains]. Pass the powder through a sieve, and preserve it in well-stoppered bottles." *U. S.*

Sodium carbonate contains ten molecules of water of crystallization, and, when heated, readily undergoes aqueous fusion. Upon continuing the heat, the water is driven off, and a white porous mass remains, which is easily reduced to powder. Dried sodium carbonate is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodii Carbonas.*) It is officially described as "a loose, white powder, conforming to the reactions and tests given under *Sodii Carbonas.* To neutralize 1 Gm. of the salt should require not less than 13·8 C.c. of normal sulphuric acid (corresponding to about 73 per cent. of anhydrous Sodium Carbonate), methyl-orange being used as indicator." *U. S.*

Medical Properties and Uses. This preparation was introduced into practice by Dr. Beddoes, who extolled its virtues in *calculous complaints.* It is applicable to the cure of such affections only when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains (0·33–1 Gm.) may be given three times a day, in the form of pill prepared with soap and aromatics. For the medical properties of this salt, see *Sodii Carbonas.*

the heat be high enough to fuse the salt, about 23 grammes of the fused carbonate will be obtained. Fused or not, this is dissolved in water, filtered, evaporated to dryness, dehydrated over a naked flame, and granulated by stirring while hot. (*A. J. P.*, 1875, 31.)

SODII CHLORAS. U. S. Sodium Chlorate.

$NaClO_3$; 106·25. (SŌ′DI-Ī ȻHLŌ′RĂS.) $NaClO_3$; 106·4.

This official salt, while manufactured on a large scale for use in the textile industries by the methods described under *Potassii Chloras*, is usually prepared on a small scale by Wittstein's process, which consists in first preparing sodium bitartrate by adding a strong solution containing 9·5 parts of tartaric acid to a hot aqueous solution of 9 parts of sodium carbonate. The hot solution is mixed with one in which 8 parts of potassium chlorate have been dissolved. Potassium bitartrate separates, whilst sodium chlorate remains in solution. The filtered solution is evaporated and crystallized. If desired of absolute purity, it may be recrystallized from an alcoholic solution. Owing to the facility with which this salt parts with its oxygen, the following official cautionary direction should be borne in mind. "Sodium Chlorate should be kept in glass-stoppered bottles, and *great caution* should be observed in handling the salt, as dangerous explosions are liable to occur when it is mixed with organic matters (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and either heated directly, or subjected to trituration or concussion." *U. S.*

Properties. It is officially described as in "colorless, transparent crystals (principally regular cubes with tetrahedral facets), or a crystalline powder, odorless, and having a cooling, saline taste. Permanent in dry air. Soluble, at 15° C. (59° F.), in 1·1 parts of water, and in about 100 parts of alcohol; in 0·5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 per cent. of its weight), and finally leaves a residue of sodium chloride, readily soluble in water, and yielding, with silver nitrate test-solution, a white, curdy precipitate insoluble in nitric acid. To a non-luminous flame it imparts an intense yellow color. The aqueous solution is neutral to litmus paper. When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color, and emits the odor of chlorine. A saturated aqueous solution should not be rendered turbid by sodium bitartrate test-solution (limit of *potassium*). An aqueous solution of the residue left after igniting a portion of the salt should not give an alkaline reaction with litmus paper (absence of *tartrate*). The aqueous solution (1 in 20), slightly acidulated with acetic acid, should not be rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, either at once (absence of *arsenic*, *lead*, etc.), or after the addition of ammonia water in slight excess (absence of *iron*, *aluminum*, etc.). The aqueous solution (1 in 20) should not be rendered turbid by adding to it a few drops of ammonia water and then sodium phosphate test-solution (absence of *magnesium*, etc.). The solution (1 in 20), slightly acidulated with acetic acid, should not be rendered turbid by ammonium oxalate test-solution (absence of *calcium*); nor by barium chloride test-solution (absence of *sulphate*); nor should silver nitrate test-solution produce in it more than a slight opalescence (limit of *chloride*)." *U. S.*

Medical Properties. Sodium chlorate has medical properties similar to those of potassium chlorate, whilst its greater solubility permits the use of stronger solutions. Dose, from five to fifteen grains (0·3–1 Gm.).

SODII CHLORIDUM. U. S., Br. Sodium Chloride.

NaCl; 58·37. (SŌ′DI-Ī ȻHLŌ′RI-DŬM.) NaCl; 58·4.

"Sodium Chloride, NaCl, is common salt, purified." *Br.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it; and, from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in assimilation and nutrition.

Natural State. Common salt exists in nature either in the solid state or in solution. In the solid state, called *rock salt*, *fossil salt*, and *sal gemmæ*, it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, it occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it exists in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany and Austria, particularly the Tyrol; in Cheshire, Eng-

land; in Spain; in various parts of Asia and Africa; in the island of St. Domingo;* and in Peru and other countries of South America. There are but few mines in the United States where rock salt is produced,—at present, one in Louisiana, two in Kansas, and a group operated by one company in the western part of the State of New York; but there are numerous salt springs, which either flow naturally or are produced artificially by sinking wells to various depths in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Michigan, Pennsylvania, Virginia, West Virginia, and New York. In the last-mentioned State the springs are the most productive, the chief ones being situated at Salina, Montezuma, and Galen. In West Virginia an important salt region exists, extending fifteen miles on both sides of the Great Kanawha River, and in Michigan in the counties of Huron, Bay, and Saginaw extensive salt wells are worked. The production of salt in 1895 was as follows: Michigan, 3,929,342 bbls. (barrels of 280 lbs.); New York, 5,919,155 bbls.; other States, 4,427,357 bbls.; total, 14,275,854 bbls.; for 1896, Michigan, 4,321,144 bbls.; New York, 6,714,394 bbls.; other States, 4,672,370 bbls.; total, 15,707,908 bbls.; for 1897, Michigan, 4,838,140 bbls.; New York, 4,172,631 bbls.; other States, 4,142,753 bbls.; total, 13,153,524 bbls. Rock salt is always transparent or translucent; but it often exhibits various colors, such as red, yellow, brown, violet, blue, etc., which are supposed to be derived from iron and manganese.

Extraction. Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure, it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine and the temperature of the place where it is found. When the water contains from 14 to 15 per cent. of the salt, it is extracted by evaporation in large iron boilers. If, however, it contains only 2, 3, 4, or 5 per cent., the salt is obtained in a different manner. If the climate be warm, it may be procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation, to be mentioned presently, and the subsequent application of artificial heat.

Sea-water is a weak saline solution, containing 2·7 per cent. of common salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt*. The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting the sea-water into shallow dikes, lined with clay, and capable, after having been filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. About 30,000 tons a year are thus made at Alameda, California, the only place in the United States where solar evaporation is carried out. In temperate climates, weak brines are first concentrated in buildings called *graduation houses*. These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall, and in its descent it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and, being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat.

Properties. Sodium chloride is white, without odor, and of a peculiar taste called saline. It is usually crystallized in cubes; but by hasty evaporation it often assumes the form of hollow quadrangular pyramids, or hopper-shaped crystals, consisting of an aggregation of cubes. It is officially described as in "colorless, transparent, cubical crystals, or a white, crystalline powder, odorless, and having a purely saline taste. Permanent in dry air. Soluble in 2·8 parts of water, at 15° C. (59° F.), and in 2·5 parts of boiling water; almost insoluble in alcohol; insoluble in ether or chloroform. When heated, the salt decrepitates. At a red heat it fuses, and at a white heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense yellow color. The aqueous solution of the salt is neutral to litmus paper. With silver nitrate test-solution, the solution yields a white, curdy precipitate, insoluble in nitric acid. No turbidity should be produced in 5 C.c. of the aqueous solution (1 in 20) by the addition of 0·5 C.c. of sodium cobaltic nitrate test-solution (limit of *potassium*). The aqueous solution, slightly acidulated with acetic acid, should not be rendered turbid by ammo-

* This deposit is on the south side of the island, and is said to form a mountain 6 miles long, from half a mile to a mile broad, and from 400 to 500 feet high. The salt in its crude state contains 96·79 per cent. of pure sodium chloride. (*A. J. P.*, Sept. 1865, p. 395.)

nium oxalate test-solution (absence of *calcium*); nor by barium chloride test-solution (absence of *sulphate*); nor by an equal volume of hydrogen sulphide test-solution, either before or after addition of ammonia water in slight excess (absence of *arsenic*, *lead*, *zinc*, *iron*, *aluminum*, etc.). No turbidity should be produced in the aqueous solution by the addition of sodium phosphate test-solution and a few drops of ammonia water (absence of *magnesium*, etc.). If 2 Gm. of the finely powdered salt be digested for some hours with 25 C.c. of warm alcohol, and, after cooling, the undissolved salt be removed by filtration, then the filtrate evaporated to dryness and the residue dissolved in 1 C.c. of water and mixed with a few drops of starch test-solution, the addition of chlorine water, drop by drop, should produce neither a blue nor a yellow tint (absence of *iodide* or *bromide*). If 0·195 Gm. of well-dried Sodium Chloride be dissolved in 10 C.c. of water, and the solution mixed with a few drops of potassium chromate test-solution, it should require not less than 33·4 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to at least 99·9 per cent. of the pure salt)." *U. S.* "In small white crystalline grains or transparent cubic crystals, free from moisture, with a purely saline taste, soluble in less than 3 parts of *water*. It affords the reactions characteristic of sodium and of chlorides. It should yield no characteristic reaction with the tests for potassium, bromides, or iodides, and only slight reactions with the tests for calcium, magnesium, or sulphates." *Br.* When pure, it undergoes no change in the air; but when contaminated with magnesium chloride, as not unfrequently happens, it is deliquescent. Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes with but partial decomposition. (Mulder, *Journ. de Pharm. et de Chim.*, 4e éd., iii.) It is decomposed by several of the acids, particularly sulphuric and nitric, which disengage vapors of hydrochloric acid; by potassium carbonate with the assistance of heat; and by silver nitrate and mercurous nitrate. In contact with iron, in the presence of air and moisture, it undergoes decomposition. (*Chem. News*, June, 1869.) It is decomposed by steam excessively heated, with the escape of hydrochloric acid and an alkaline residue. (*Chem. News*, June 4, 1875.) Several varieties of common salt are distinguished in commerce, as *stored salt*, *fishery salt*, *bay salt*, etc.; but they are characterized by the size and compactness of the grains, and not by any difference in composition.

Composition. Common salt, in its pure state, consists of one atom of chlorine and one of sodium. It contains no water of crystallization. The common salt of commerce, besides pure sodium chloride, contains, generally speaking, insoluble matter, and usually more or less of calcium and magnesium sulphates and calcium and magnesium chlorides. When pure, it is not precipitated by sodium carbonate, barium chloride, or potassium ferrocyanide. Calcium chloride is generally present in very small amount; but the magnesium chloride sometimes amounts to 28 parts in 1000. Calcium sulphate is usually present, constituting variously from 1 to 23½ parts in 1000; and magnesium sulphate is sometimes present and sometimes absent. To separate the earths, a boiling solution of sodium carbonate must be added as long as any precipitate is formed. The earths will form as carbonates, and must be separated by filtration, and the sodium sulphate and sodium chloride resulting from the double decomposition will remain in solution. The sodium sulphate may then be decomposed by the cautious addition of barium chloride, which will generate sodium chloride and insoluble barium sulphate.

Medical Properties. Sodium chloride, in small doses, acts as a stomachic tonic and anthelmintic, in larger ones as a purgative and emetic. From the experiments of Prof. Buchheim, it appears that common salt quickly passes into the blood, and is thrown off in greater part, in six hours, by the kidneys. The portion not found in the urine and fæces is probably appropriated to the uses of the economy. M. Plouviez, as the result of experiments made upon himself, came to the conclusion that the use of a saline regimen has the effect of increasing the number of the red blood-corpuscles as well as the weight and strength of the body. This is, however, contradicted by the more recent experiments of Dr. Münch, and the common experience of mankind seems to show that, whilst the habitual use of a certain amount of the salt is necessary for health, over-use of it has no effect in producing plethora.

Common salt has been used with good effect by a number of practitioners as a remedy in *intermittent fever*. It is not alleged to be equal to quinine. The dose is from eight to twelve drachms (31·1–46·6 Gm.), given in divided doses during the apyrexia. It is best administered in mucilage of slippery elm, or in coffee. In *hæmoptysis*, common salt, in the dose of a teaspoonful (3·9 Gm.), taken dry, often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally, it is sometimes employed as a fomentation in *sprains* and *bruises;* and as a general external

application it forms the salt-water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, especially when occurring in children. A pound of salt dissolved in four gallons of water forms a solution of about the strength of sea-water, and suitable for a bath. Dose: as a cathartic, from two drachms to half an ounce (7·8–15·5 Gm.); as an emetic, from half an ounce to an ounce (15·5–31·1 Gm.), dissolved in four or five times its weight of water. It is frequently used as a clyster, two tablespoonfuls in a pint of water.

The uses of common salt in domestic economy as a condiment and an antiseptic are well known. In pharmacy it is employed to prepare chlorine, hydrochloric acid, ammonium chloride, calomel, and corrosive sublimate. It is also used to form sodium sulphate, with a view to its conversion into sodium carbonate.

SODII CITRO-TARTRAS EFFERVESCENS. Br. Effervescent Sodium Citro-Tartrate.

(SŌ′DI-Ī CĪ′TRŌ-TĂR′TRĂS ĔF-FĔR-VĔS′CĔNȘ.)

"Sodium Bicarbonate, in powder, 51 *ounces* (Imperial) or 510 grammes; Tartaric Acid, in powder, 27 *ounces* (Imp.) or 270 grammes; Citric Acid, in powder, 18 *ounces* (Imp.) or 180 grammes; Refined Sugar, in powder, 15 *ounces* (Imp.) or 150 grammes. Mix the powders thoroughly; place the mixture in a dish or pan of suitable form heated to between 200° and 220° F. (93·3° and 104·4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (Imp.) or 1000 grammes." *Br.*

The object of this combination is to furnish sodium citrate and tartrate in a convenient and portable form. As the water has been driven off by heat, no reaction takes place until dissolved in water, when the two acids combine with the soda of the bicarbonate to produce sodium tartrate and citrate, and the carbonic acid escapes with brisk effervescence. It is in this form that the preparation is intended to be used. The salts combine laxative with refrigerant properties, which adapt them to the *febrile state*, while the carbonic acid renders them acceptable to the stomach, and will often check *nausea* and *vomiting*. The dose is from one to two drachms (3·9–7·8 Gm.), which may be taken in a small wineglassful or more of water, and repeated occasionally as required.

SODII HYPOPHOSPHIS. U. S., Br. Sodium Hypophosphite.

$NaH_2PO_2.H_2O$; 105·84. (SŌ′DI-Ī HĪ-PŌ-PHŌS′PHĪS.) $NaH_2PO_2.H_2O$; 106.

"Sodium Hypophosphite should be kept in well-stoppered bottles." *U. S.* "Sodium Hypophosphite, $NaPH_2O_2$, is obtained by the interaction of sodium carbonate and calcium hypophosphite." *Br.*

Natrum Hypophosphorosum, Hypophosphis Sodicus; Hypophosphite of Soda; Hypophosphite de Soude, *Fr.*; Unterphosphorigsaures Natron, *G.*

Sodium hypophosphite is prepared by mixing solutions of calcium hypophosphite and crystallized sodium carbonate, in the proportion of six ounces of the former dissolved in four pints of water to ten of the latter in one and a half pints. Double decomposition takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution and the former is precipitated. After filtration to separate the calcium carbonate, the solution is evaporated to a pellicle, and then stirred constantly till the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sometimes sodium hypophosphite explodes with violence during the evaporation of its solution. This was ascribed to the use of too high a heat; but the same accident has occurred when the heat was applied by means of a water-bath. (See *A. J. P.*, 1860, p. 87.) In a communication of Mr. Tuson to the *Chemical News* (No. 31, p. 46), it is stated that, though he had superintended the manufacture of large quantities of calcium and sodium hypophosphites, he had never witnessed anything like an explosion; but the heat employed in evaporation had never approached 100° C. (212° F.); and this is probably the true explanation. Caution, therefore, should be observed to evaporate at a low temperature.

Properties. Sodium hypophosphite occurs in "small, colorless, transparent, rectangular plates of a pearly lustre, or a white granular powder, odorless, and having a bitterish-sweet, saline taste. Very deliquescent on exposure to moist air. Soluble, at 15° C. (59° F.), in 1

part of water, and in 30 parts of alcohol; in 0·12 part of boiling water, and in 1 part of boiling alcohol; slightly soluble in absolute alcohol; insoluble in ether. When heated in a test-tube, the salt at first loses its water of crystallization, and at about 200° C. (392° F.) it is decomposed, evolving hydrogen and hydrogen phosphide, which burn with a bright yellow flame. Finally there is left a residue of sodium pyrophosphate and metaphosphate, sometimes mingled with a little red phosphorus. To a non-luminous flame the salt communicates an intense, yellow color. On triturating or heating Sodium Hypophosphite with nitrates, chlorates, or other oxidizing agents, it detonates violently. The aqueous solution is neutral to litmus paper. A 5-per-cent. aqueous solution of the salt yields, with silver nitrate test-solution, a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added in small quantity to an excess of mercuric chloride test-solution, a white precipitate of mercurous chloride is formed. On further addition of the solution, the precipitate is reduced to metallic mercury. A solution of 0·5 Gm. of the salt in 1 C.c. of water should yield no precipitate upon the addition of 1 C.c. of sodium bitartrate test-solution (limit of *potassium*). The aqueous solution (1 in 20) should not be colored red by the addition of a drop of phenolphtalein test-solution, nor effervesce on the addition of an acid (absence of *caustic alkali* or *carbonate*); nor should it be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). In the aqueous solution (1 in 20), acidulated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution should not produce any turbidity (absence of *arsenic*, *lead*, etc.). After heating 10 C.c. of the aqueous solution (1 in 20) with 1 C.c. of nitric acid, separate portions of the solution should remain clear upon the addition of silver nitrate test-solution (absence of *chloride*), and of barium chloride test-solution (absence of *sulphate*). Not more than a slight cloudiness should be produced in the aqueous solution of the salt by magnesia mixture (limit of *phosphate*). Potassium ferrocyanide test-solution should not produce in the acidulated solution any blue color (absence of *iron*). If 0·1 Gm. of dry Sodium Hypophosphite be dissolved in 10 C.c. of water, mixed with 7·5 C.c. of sulphuric acid and 40 C.c. of potassium permanganate decinormal volumetric solution, and the mixture boiled for fifteen minutes, it should require not more than 3 C.c. of oxalic acid decinormal volumetric solution to discharge the red color, corresponding to at least 97·96 per cent. of the pure salt." *U. S.* "A white granular salt, having a bitter nauseous taste. It is deliquescent, soluble in its own weight of *water* and in 30 parts of *alcohol* (90 per cent.), but insoluble in *ether*. When heated in air it yields spontaneously inflammable hydrogen phosphide and hydrogen. It colors flame strongly yellow. It is rapidly attacked by oxidizing agents. Its solution yields with a warm solution of *copper sulphate* a red precipitate of cuprous hydride, which, on boiling, evolves hydrogen. 0·5 gramme boiled for ten minutes with 25 cubic centimetres of *water* and 1·15 grammes of *potassium permanganate*, and filtered, should afford a nearly colorless solution. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, chlorides, or sulphates, only the slightest reactions with the tests for carbonates, and its solution should give little or no precipitate with *solution of lead acetate* (limit of phosphates and phosphites)." *Br.*

Hypophosphorous acid consists of one atom of phosphorus, two of oxygen, and three of hydrogen, of which, however, only one is replaceable by metal. It has a strong affinity for oxygen, and acts therefore as a powerful deoxidizing agent, as is shown by its reducing silver and mercury from their salts. The solubility of sodium hypophosphite is increased by the addition of hypophosphorous acid. As the soluble salts of mercury and silver are reduced by the hypophosphites, they are of course incompatible with sodium hypophosphite in prescriptions. With calcium hypophosphite, all the soluble sulphates and carbonates produce precipitates.

Medical Properties and Uses. Attention was first directed to the use of the hypophosphites in the treatment of *phthisis* by Dr. Churchill, of Paris. The weight of testimony appears to be opposed to the first favorable impressions; and, though some cases may have seemed to be benefited, yet great care must be taken not to allow a reliance on the hypophosphites to interfere with the use of remedies known to be efficient, as cod-liver oil and supporting measures generally. Dr. J. D. Brown, of the Albany City Hospital, has found the hypophosphites highly useful in diseases attended with *loss of nerve-power*, and in many of the complaints of infancy connected with the *scrofulous diathesis* and *defect in the osseous system.* (*Boston Med. and Surg. Journ.*, lxxiii. 412, Dec. 21, 1865.) The dose of either of the alkaline hypophosphites may be from ten to twenty grains (0·65–1·31 Gm.), three times a day.

SODII HYPOSULPHIS. U.S. (Br.) Sodium Hyposulphite.

$Na_2S_2O_3.5H_2O$; 247·64. (SŌ'DI-Ī HĪ-PŌ-SŬL'PHĪS.) $Na_2S_2O_3.5H_2O$; 248.

"Sodium Hyposulphite should be kept in well-stoppered bottles." *U. S.*

Sodium Thiosulphate; Natrum Subsulfurosum (Hyposulfurosum), *P. G.;* Hyposulphis Sodicus; Hyposulphite de Soude, Sulfite sulfuré de Soude, *Fr.;* Unterschwefligsaures Natron, *G.*

This salt is used in the United States and British Pharmacopœias as a test, and for the formation of the *Volumetric Solution of Sodium Hyposulphite.* It is readily prepared, according to Walchner, by mixing a pound of dry sodium carbonate, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sodium sulphide first formed is thus converted into sodium sulphite. This is dissolved in water, and the filtered solution being boiled with sulphur becomes one of sodium hyposulphite, from which, after filtration and concentration, the salt is deposited in crystals. It may be obtained also by digesting the solution of sodium sulphite at a high temperature, but short of ebullition, with finely divided sulphur. Hyposulphurous acid exists only in combination; and its salts were formerly considered simply as sulphuretted sulphites. The true hyposulphurous acid, according to theory, would be H_2SO_2, while $H_2S_2O_3$ is more properly *thiosulphuric* acid, as it differs from sulphuric acid by the replacement of one oxygen atom by one sulphur atom. Inasmuch as Schützenberger has recently discovered the true hyposulphurous acid, H_2SO_2, exact chemical usage would demand that we give the distinguishing name thiosulphuric to what was formerly called hyposulphurous. Schützenberger himself called the newly-discovered acid *hydrosulphurous*, but this is not characteristic, and the correct name for the official sodium hyposulphite is *sodium thiosulphate.*

Properties. It is officially described as in "colorless, transparent, monoclinic prisms, odorless, and having a cooling, afterwards bitter taste. Permanent in the air below 33° C. (91·4° F.), but efflorescent in dry air above that temperature. Soluble in 0·65 part of water at 15° C. (59° F.), and in about 0·5 part at 20° C. (68° F.); at a boiling heat the solution is rapidly decomposed. Insoluble in alcohol; slightly soluble in oil of turpentine. When rapidly heated to about 50° C. (122° F.), the salt melts. When slowly heated until it is effloresced, and afterwards to 100° C. (212° F.), it loses all its water of crystallization (36·3 per cent.), and at a red heat is decomposed, sulphur being evolved, while a residue of sodium sulphide and sulphate remains. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. An aqueous solution of the salt readily dissolves many salts of silver (chloride, bromide, iodide, oxide, etc.), and discharges the color of a solution of iodine or of starch iodide. If ferric chloride test-solution be dropped into the aqueous solution (1 in 20), a dark violet color will be produced, which disappears rapidly on agitation. Addition of sulphuric or hydrochloric acid to the aqueous solution liberates from it sulphur dioxide (known by its odor, and by its blackening a strip of paper moistened with mercurous nitrate test-solution and held in the escaping gas), and causes a white precipitate of sulphur (distinction from *sulphite* or *bisulphite*). If to 5 C.c. of the aqueous solution (1 in 20) an equal volume of hydrogen sulphide test-solution be added, no coloration or turbidity should be perceptible either before or after the addition of 1 C.c. of ammonia water (absence of *lead*, *iron*, etc.). The aqueous solution should not be rendered turbid by the addition of ammonium oxalate test-solution (absence of *calcium*). The aqueous solution of the salt (1 in 20) should not be colored red by a drop of phenolphtalein test-solution (absence of *caustic alkali*, or *carbonate*); nor should a drop of silver nitrate test-solution produce a brown or a black precipitate in 5 C.c. of this solution (absence of *sulphide*). In a dilute aqueous solution (1 in 80), barium chloride test-solution should produce no turbidity (absence of *sulphate*). If 0·25 Gm. of Sodium Hyposulphite be dissolved in 10 C.c. of water and a few drops of starch test-solution added, it should require at least 9·9 C.c. of iodine decinormal volumetric solution to produce a permanent blue color (corresponding to at least 98·1 per cent. of the pure salt)." *U. S.* Its solution dissolves silver chloride and all water-insoluble compounds of that metal, except the sulphide, and that resulting from the decomposition of a silver salt by light. Though without action on potassium iodide, it dissolves iodine, decomposes iodic acid with liberation of iodine, and destroys the blue color of starch iodide. (*Brande and Taylor.*) In dissolving iodine it forms with it sodium iodide and sodium tetrathionate, as represented by the formula $2(Na_2S_2O_3) + I_2 = (NaI)_2 + Na_2S_4O_6$. It dissolves also lead sulphate and iodide, and calcium sulphate, much more freely than does water. (*Journ. de Pharm.*,

1864, 363.) Its relations to iodine render it valuable as a means of estimating the quantity of free iodine, for which purpose it is used in the Pharmacopœias in the form of a *volumetric solution*. In consequence of its peculiar solvent properties, it is much used in photography. The photographers employ it for the purpose of dissolving the unchanged silver iodide or bromide from the plate after the action of the light, and thus fixing the image already formed. It is also largely used as an "*antichlor*" in the paper manufacture, to free the paper pulp from the excess of chlorine used in the bleaching. One of the most delicate tests is that of iodine with starch. The blue color produced by the mixture of very small quantities of these two substances in solution is instantly discharged by a solution containing a trace of the hyposulphite. If zinc or iron is dipped into an acidified solution of the hyposulphite, the liberated hydrogen at once reduces the sulphurous oxide which is in the solution to hydrogen sulphide, recognizable by lead acetate paper. This test will serve to show even traces of hyposulphite. Flückiger states that the annual production of sodium thiosulphate (hyposulphite) amounts to about 500,000 kilos.

Medical Properties. Sodium hyposulphite is a very powerful poison to fungi and other low organic forms. Consequently, when added to fermenting mixtures it arrests the process of change. This led Dr. G. Polli to suggest its use in certain diseases supposed to be dependent on a fermentation or zymosis in the blood. The theory has seemed plausible to many practitioners, and the remedy has been extensively administered in *pyæmia* and in the so-called *zymotic disorders* and allied affections. Although individual experiences corroborating the early successes of Polli have been reported, the general professional verdict is unmistakably adverse. The hyposulphite seems not to be without influence upon the human system. When taken internally it appears to have deoxidizing powers, probably through the passage of the hyposulphurous into sulphuric acid. It has been found, in its action on the urine, to diminish urea and increase uric acid, to increase the sulphates, and to cause the presence of sugar and oxalic acid in the urine. (Kletzinsky, *Ann. de Thérap.*, 1860, p. 109.) With a view to its poisonous influence on the sarcina ventriculi which attends *yeasty vomiting*, it has been employed in that complaint; and, as a local application, it may be used in all the *parasitic affections of the skin and mouth*. It may be given in the dose of from ten to twenty grains (0·65–1·3 Gm.), three times a day simply dissolved in water, or in the form of syrup. For external use a drachm may be dissolved in a fluidounce of water. As the effects of this salt proceed from its acid constituent, other hyposulphites may be substituted; and *calcium hyposulphite* has been recommended. For the mode of preparing the latter salt, see *A. J. P.*, 1863.

SODII IODIDUM. U. S., Br. Sodium Iodide.

NaI; 149·53. (SŌ′DI-Ī Ī-ŌD′I-DŬM.) NaI; 149·6.

"Sodium Iodide should be kept in well-stoppered bottles." *U. S.* "Sodium Iodide, NaI, may be prepared from iodine and sodium hydroxide by a process similar to that employed in making Potassium Bromide; the salt being crystallized at a temperature of not less than 68° F. (20° C.)." *Br.*

Natrum Iodatum; Iodure de Sodium, *Fr.;* **Jodnatrium,** *G.*

This iodide may be prepared either by treating a solution of caustic soda with iodine, or by double decomposition between ferrous iodide and sodium carbonate, precisely as potassium iodide is obtained by the corresponding processes for that salt. As only small quantities are likely to be wanted as a medicine, the latter process is preferable, being more easily conducted on a small scale.

Properties. It is a very soluble white salt, crystallizing in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with two mols. of water, by spontaneous evaporation. It is officially described as in "colorless, cubical crystals, or a white, crystalline powder, odorless, and having a saline and slightly bitter taste. In moist air it deliquesces and becomes partially decomposed into sodium carbonate and free iodine, assuming, thereby, a reddish color. Soluble, at 15° C. (59° F.), in 0·6 part of water, and in about 3 parts of alcohol; in 0·33 part of boiling water, and in 1·4 parts of boiling alcohol. When heated, the salt melts, and at a bright red heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral or but feebly alkaline to litmus paper. If to 5 C.c. of the aqueous solution (1 in 20) 1 C.c. of chlorine water be added, iodine will be liberated and impart to the solution a yellow color. On agitating this mixture with a few drops of chloroform, the latter will acquire a violet color. If the salt be in distinct

crystals, only few monoclinic prisms (containing 2 molecules of water) should be found among the regular cubes of the anhydrous salt. On drying 1 Gm. of the salt at 100° C. (212° F.), it should not lose more than 0·05 Gm. in weight (absence of more than 5 per cent. of *water*). A solution of 1 Gm. of the salt in 1 C.c. of water should yield no precipitate with 1 C.c. of sodium bitartrate test-solution (limit of *potassium*). The aqueous solution (1 in 20), slightly acidulated with acetic acid, should remain clear after the addition of ammonium oxalate test-solution (absence of *calcium*), or of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, etc.). The addition of ammonium sulphide test-solution should not produce either a coloration or a turbidity in the aqueous solution (absence of *zinc*, *iron*, *aluminum*, etc.). If 1 Gm. of the salt be dissolved in water, and 0·05 C.c. (1 drop) of oxalic acid decinormal volumetric solution added, no red color should be produced by the addition of a drop of phenolphtalein test-solution (limit of *alkali*). The aqueous solution, slightly acidulated with hydrochloric acid, should not be colored blue upon the addition of potassium ferrocyanide test-solution (absence of *iron*). If 0·5 Gm. of the salt be dissolved in 10 C.c. of freshly boiled distilled water, and the solution mixed with a few drops of starch test-solution, no blue color should appear either at once (absence of *free iodine*), or after the addition of a drop of diluted hydrochloric acid (absence of *iodate*). If 5 C.c. of the aqueous solution (1 in 20) be acidulated with hydrochloric acid, and 0·5 C.c. of barium chloride test-solution added, no immediate turbidity should appear (limit of *sulphate*). If 5 C.c. of the aqueous solution be gently heated with 1 drop of ferrous sulphate test-solution and 0·5 C.c. of potassium hydrate test-solution, no blue color should appear after acidulating the mixture with hydrochloric acid (absence of *cyanide*). If 1 Gm. of the salt be mixed with 0·5 Gm. of iron filings and 0·5 Gm. of powdered zinc, and heated in a test-tube with 5 C.c. of sodium hydrate test-solution, no ammoniacal vapors should be evolved (absence of *nitrate* or *nitrite*). If 0·5 Gm. of the well-dried salt be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution added, it should not require more than 34·5 C.c. nor less than 33·4 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to at least 98 per cent. of the pure salt)." *U. S.* "A dry white crystalline deliquescent powder, having a saline and somewhat bitter taste, readily soluble in less than its weight of *water* and in 3 parts of *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of iodides. Each gramme should not lose more than 0·05 gramme of water when dried at 248° F. (120° C.); and each gramme of this dried salt, when dissolved in *water*, should require for complete precipitation not less than 66·5 cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, calcium, magnesium, potassium, ammonium, bromates, cyanides, carbonates, or iodates, and only the slightest reactions with the tests for bromides, chlorides, or sulphates." *Br.*

Medical Properties. Sodium iodide has the same therapeutic effects and is used in the same diseases as potassium iodide. It is said to be better borne than the latter iodide. In Italy it has been used with remarkable success in *constitutional syphilis*. The dose is twenty grains (1·3 Gm.), gradually increased to forty (2·6 Gm.), three times a day, dissolved in three fluidounces (90 C.c.) of water. (See Prof. Procter's paper on the preparation of this iodide, in *A. J. P.*, July, 1854, p. 305.) At the suggestion of Prof. Gross, it was employed by Dr. John J. Black, at the Philadelphia Hospital, as a substitute for potassium iodide in the treatment of syphilitic affections, and seemed to be not less efficacious than that medicine, while producing none of its unpleasant effects. (*Am. Journ. of the Med. Sci.*, July, 1865, p. 87.)

SODII NITRAS. U. S. Sodium Nitrate.

$NaNO_3$; 84·89. (SŌ'DI-Ī NĪ'TRĂS.) $NaNO_3$; 85.

"Sodium Nitrate should be kept in well-stoppered bottles." *U. S.*

Nitrate of Soda, Cubic Nitre; Natrum Nitricum, *P. G.*; Nitras (Azotas) Sodicus, Nitrum Cubicum; Azotate (Nitrate) de Soude, Nitre cubique, Nitrate de Chili, *Fr.*; Chili-Salpeter, *G.*

This salt, called also *cubic nitre*, was recognized as official in 1870. Sodium nitrate is imported from South America, where it is found naturally, especially in the desert of Atacama, forming beds of vast extent. The nitrate deposits have been found uniformly through a zone 250 geographical miles in length north to south, and two geographical miles in width east to west. It is estimated that the nitrate beds contain the enormous quantity of 99,031,525 tons, and it is stated that with the present export duty the deposits will yield a revenue of

£230,809,474. (*Journ. Soc. Chem. Ind.*, 1887, 229.) Attempts were made between 1820 and 1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value became known. The salt has been found also largely in Brazil, in the province of Bahia, near the river San Francisco. (*A. J. P.*, Nov. 1861, 502.) For an account of the sodium nitrate deposits of Chili, see *Potassii Nitras*. The shipments of sodium nitrate from South American ports to all parts amounted in 1895 to 1,218,000 tons and in 1896 to 1,088,000 tons. The importations into the United States were, 1895, 118,477 tons; 1896, 115,504 tons; and 1897, 94,965 tons. The crude salt is in saline lumps, rather soft and friable, and damp on the surface. Its varieties are classified, according to their color and state of aggregation, as *white compact*, *yellow*, *gray compact*, *gray crystalline*, *white crystalline*. The "*caliche*," as the crude mineral is called, contains from 48 to 75 per cent. of sodium nitrate, from 20 to 40 per cent. of sodium chloride, and smaller amounts of sodium sulphate, calcium sulphate, potassium nitrate, and potassium and sodium iodate (from 0·059 to 0·175 per cent. of iodine). Occasionally calcium borate, associated with sodium borate, is found under the beds of the nitrate.

Arrangements have been made for treating the crude nitrate so as to deliver it to commerce in a state of great purity. Exposure of the mineral to an open fire, which seems to have been first employed, has been entirely superseded by mechanical methods aided by steam, to prepare it for the subsequent steps of solution, crystallization, and desiccation. The Chilian nitre, prepared by the "Nitre Association of Tarapaca," never contains more than 0·5 or 0·667 per cent. of impurities. It is white, pearly, dry, and light, and does not require to be refined for the practical uses to which it is applied. (Thiercelin, *Journ. de Pharm.*, Juin, 1868, p. 439.)

Properties. Sodium nitrate, when pure, is in "colorless, transparent, rhombohedral crystals, odorless, and having a cooling, saline, and slightly bitter taste. Deliquescent in moist air. Soluble, at 15° C. (59° F.), in 1·3 parts of water, and in about 100 parts of alcohol; in 0·6 part of boiling water, and in 40 parts of boiling alcohol. When heated at 312° C. (593·6° F.), the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. On red-hot charcoal it deflagrates. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. If the aqueous solution be mixed in a test-tube with a drop of diphenylamine test-solution, and sulphuric acid be carefully poured in, so as to form a separate layer, a deep blue color will appear at the line of contact. A solution of 0·5 Gm. of the salt in 1 C.c. of water should not be precipitated or rendered turbid by 1 C.c. of sodium bitartrate test-solution (limit of *potassium*). The aqueous solution (1 in 20) should not be colored or rendered turbid by the addition of hydrogen sulphide test-solution or ammonium sulphide test-solution (absence of *arsenic* and *metallic impurities*); nor by the addition of equal parts of ammonia water and sodium phosphate test-solution (absence of *calcium*, *magnesium*, etc.). If the aqueous solution be mixed with a few drops, each, of hydrogen sulphide test-solution and starch test-solution, and then some chlorine water poured carefully upon the mixture, no blue color should appear at the line of contact (absence of *iodate* and *iodide*). No turbidity should be produced within five minutes in the aqueous solution, acidulated with nitric acid, on the addition of either barium chloride test-solution (limit of *sulphate*), or silver nitrate test-solution (limit of *chloride*)." *U. S.* Like potassium nitrate, it deflagrates when thrown on the fire, but it is distinguished by giving rise to an orange-yellow flame, and by the rhomboidal shape of its crystals, those of nitre being long six-sided prisms. It evolves ruddy fumes when warmed in a test-tube with sulphuric acid and copper wire.

Medical Uses. This salt has been praised as a remedy in *dysentery* (see 15th ed. *U. S. D.*), in the dose of from half an ounce to an ounce (15·5–31·1 Gm.) in the course of the day in dilute solution, but is at present very rarely, if ever, used in practical medicine.

SODII NITRIS. U. S., Br. Sodium Nitrite.

$NaNO_2$; 68·93. (SŌ′DI-Ī NĪ′TRĪS.)

"Sodium Nitrite should be kept in well-stoppered bottles." *U. S.* "A salt, $NaNO_2$, obtained by fusing sodium nitrate with metallic lead." *Br.*

Nitrite of Sodium, Nitrite of Soda.

This salt is official in the U. S. Pharmacopœia of 1890 for the first time: it has been introduced for the purpose of furnishing the nitrous radical to ethyl nitrite in the preparation of spirit of nitrous ether. (See *Spiritus Ætheris Nitrosi*.) It is officially described as in "white,

opaque, fused masses, usually in the form of pencils, or colorless, transparent, hexagonal crystals; odorless, and having a mild, saline taste. When exposed to the air, the salt deliquesces and is gradually oxidized to sodium nitrate. Soluble in about 1·5 parts of water at 15° C. (59° F.), and very soluble in boiling water; slightly soluble in alcohol. When heated, the salt melts, and at a red heat it is decomposed, yielding oxygen, nitrogen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an alkaline reaction with litmus paper. If the aqueous solution of the salt be mixed with some potassium iodide test-solution, and a few drops of an acid added, iodine will be liberated, and nitrogen dioxide gas will escape with effervescence. The salt should readily dissolve in 20 parts of water, forming a colorless solution, and leaving no insoluble residue (absence of *insoluble impurities*). If 1 drop of hydrochloric acid and a few drops of starch test-solution be added to 5 C.c. of the aqueous solution, no blue coloration should appear (absence of *iodide*). If 5 C.c. of the aqueous solution be mixed with an equal volume of hydrogen sulphide test-solution, no coloration or precipitate should be produced (absence of *lead*, *arsenic*, *copper*, etc.). If 0·15 Gm. of Sodium Nitrite be dissolved in 5 C.c. of water, and introduced into a nitrometer, then followed by a solution of 1 Gm. of potassium iodide in 6 C.c. of water and 15 C.c. of normal sulphuric acid, the liberated nitrogen dioxide gas should measure not less than 50 C.c. at 15° C. (59° F.), or 51·7 C.c. at 25° C. (77° F.), corresponding to not less than 97·6 per cent. of the pure salt." *U. S.* The British Pharmacopœia defines it as "A white deliquescent crystalline powder, very soluble in *water*. The solution is neutral or slightly alkaline, and affords reactions characteristic of sodium salts and of nitrites. 0·1 gramme dissolved in *water*, introduced into a brine-charged nitrometer, and tested with *potassium iodide* and *diluted sulphuric acid*, should liberate at the ordinary temperature (60° F. or 15·5° C.) and pressure (30 inches or 760 millimetres of mercury) not less than 32·5 cubic centimetres of nitric oxide, corresponding to not less than 95 per cent. of sodium nitrite, the gas being almost completely absorbed by strong solution of *ferrous sulphate*. The aqueous solution of the salt should not give more than the slightest traces of a precipitate on the addition of *diluted sulphuric acid* (absence of lead)."

Medical Properties and Uses. Sodium nitrite acts upon the animal organism precisely as do the other nitrites, being more slowly absorbed, however, and much less rapidly eliminated. Its influence is, therefore, more slowly manifested and much more permanent than is that of amyl nitrite or nitroglycerin. Ten grains are sufficient to cause flushing of the face and markedly increased heart-action; indeed, five grains are said to have produced serious symptoms. (*London Lancet*, ii. 1883.) It is evident that, although twenty grains of the commercial sodium nitrite have been given without serious effect, the dose of the pure article should not exceed three grains (0·19 Gm.).

SODII PHOSPHAS. U. S., Br. Sodium Phosphate. [Sodium Orthophosphate.]

$Na_2HPO_4.12H_2O$; 357·32. (SŌ'DI-Ī PHŌS'PHĂS.) $Na_2HPO_4.12H_2O$; 358.

"Sodium Phosphate should be kept in well-stoppered bottles, in a cool place." *U. S.* "This salt, di-sodium hydrogen phosphate, $Na_2HPO_4,12H_2O$, may be obtained by the interaction of sodium carbonate and the solution of acid calcium phosphate produced on mixing bone-ash and sulphuric acid." *Br.*

Medicinal Tribasic Sodium Phosphate, Phosphate of Soda; Natrum Phosphoricum, *P. G.;* Phosphas Sodicus (Natricus), Sal Mirabile Perlatum; Phosphate de Soude, *Fr.;* Phosphorsaures Natron, *G.*

A process for this salt is no longer official; for that of the U. S. P. 1870, see foot-note.*

The incombustible part of bones is obtained by burning them to whiteness, and consists of neutral calcium phosphate, called bone-phosphate, associated with some calcium carbonate, etc. (See *Os Ustum.*) When this is mixed with sulphuric acid, the calcium carbonate is entirely de-

* *Sodii Phosphas.* "Take of Bone, calcined to whiteness and in fine powder, *one hundred and twenty troyounces;* Sulphuric Acid *seventy-two troyounces;* Carbonate of Sodium, Water, each, *a sufficient quantity.* Mix the powder with the Sulphuric Acid in an earthen vessel; then add eight pints of Water, and, having stirred the mixture thoroughly, digest for three days, occasionally adding a little Water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of that time, pour in eight pints of boiling Water, and strain through muslin, gradually adding more boiling Water until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, and, having poured off the clear solution, boil it down to eight pints. To the concentrated liquid, poured off from the newly-formed dregs and heated in an iron vessel, add by degrees Carbonate of Sodium, previously dissolved in hot Water, until effervescence ceases, and the phosphoric acid is completely saturated; then filter the liquid, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Sodium to the liquid, so as to render it slightly alkaline; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, keep the crystals in a well-stopped bottle." *U. S.*

composed, giving rise to effervescence. The calcium phosphate undergoes partial decomposition; the greater part of the lime, being detached, precipitates as calcium sulphate, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as an acid calcium phosphate, holding dissolved a small portion of the calcium sulphate. In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as acid phosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of acid calcium phosphate, are mixed and allowed to stand; and by cooling a portion of calcium sulphate is deposited, which is got rid of by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The carbonic acid is liberated with effervescence, and the alkali, combining with the *excess* of acid of the acid phosphate, produces a sodium phosphate; while the acid calcium phosphate, by the loss of its excess of acid, becomes the neutral phosphate and precipitates. The calcium phosphate is separated by a new filtration; and the filtered liquor, which is a solution of sodium phosphate, is evaporated so as to crystallize.

In the U. S. process of 1870 the calcined bone is to the acid as 10 to 6; in the Br. process of 1867 as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6·66. The acid, in the former official process, was added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that sodium phosphate crystallizes more readily by allowing its solution to be slightly alkaline; and a remarkable fact is, that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother-water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following cheap and expeditious method for obtaining sodium phosphate. To the powdered calcined bone, diffused in water, sufficient diluted sulphuric acid is added to decompose all the calcium carbonate which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the calcium phosphate and leaves the sulphate. The nitric solution of the phosphate is then treated with sodium sulphate, equal in quantity to the bone employed; and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, calcium sulphate and sodium phosphate are formed, the latter of which is separated by water, and crystallized in the usual manner.

Properties. The medicinal sodium phosphate is in "large, colorless, monoclinic prisms, odorless, and having a cooling, saline taste. The crystals effloresce in the air, and gradually lose 5 molecules of their water of crystallization (25·1 per cent.) Soluble in 5·8 parts of water at 15° C. (59° F.), and in somewhat less than 1·5 parts of boiling water; insoluble in alcohol. When heated to about 40° C. (104° F.), the salt fuses, yielding a colorless liquid. At 100° C. (212° F.), it loses all its water of crystallization (60·3 per cent.), and at a red heat it is converted into sodium pyrophosphate. It imparts to a non-luminous flame an intense, yellow color. The aqueous solution is slightly alkaline to litmus paper, but not to phenolphtalein paper. A 5-per-cent. aqueous solution of the salt yields a white precipitate with magnesia mixture. With silver nitrate test-solution it yields a yellow precipitate, soluble in ammonia water and in nitric acid. If 0·5 C.c. of the aqueous solution (1 in 20) be mixed with 1 C.c. of ammonium molybdate test-solution, the mixture will at once assume a yellow color, and, after a few minutes, yield a yellow precipitate, the appearance of which is hastened by a gentle heat. No residue should be left on dissolving the salt in water (absence of *calcium*, etc.). No turbidity or coloration should be produced in the aqueous solution by the addition of a small quantity of ammonium sulphide test-solution; or of an equal volume of hydrogen sulphide test-solution after the addition of a few drops of hydrochloric acid (absence of *metallic impurities*). If 1 Gm. of the powdered salt be shaken with 3 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), then a small piece of pure tin-foil added, and a gentle heat applied, no brown coloration should appear within fifteen minutes (limit of *arsenic*). If 0·5 Gm. of the salt be dissolved in 4 C.c. of water, and 1 C.c. of sodium bitartrate test-solution then added, the solution should remain perfectly clear (limit of *potassium*). No effervescence

should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of *carbonate*). On adding to 5 C.c. of the aqueous solution (1 in 20) 0·5 C.c. of silver nitrate test-solution, a pure yellow precipitate will be formed, which should not become dark-colored by heating (absence of *hypophosphite*, etc.), and which, upon the addition of nitric acid, should yield a perfectly clear, or, at most, only a very slightly opalescent liquid (limit of *chloride*). If to 5 C.c. of the aqueous solution, acidulated with hydrochloric acid, 0·5 C.c. of barium chloride test-solution be added, the solution should not be rendered more than very slightly opalescent (limit of *sulphate*)." *U. S.* "In transparent colorless rhombic prisms, terminated by four converging planes, efflorescent, having an alkaline reaction and a saline taste. It is soluble in 6 parts of cold *water*. It affords the reactions characteristic of sodium and of phosphates. Heated to dull redness, it loses 62·84 per cent. of its weight." *Br.* Before the blowpipe it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is liable to adulteration, sometimes containing sodium carbonate, from this salt having been added in excess in its preparation; in which case it will effervesce with acids. If it contain sodium sulphate, or any other soluble sulphate, the precipitate caused by barium chloride will be a mixture of barium sulphate and phosphate, and will not be totally soluble in nitric acid. Dr. A. B. Lyons found a specimen which consisted almost entirely of sodium sulphate. (*A. J. P.*, 1875, 371; see also *N. R.*, April, 1877.) Barium chloride will detect sodium carbonate also, by producing a precipitate of barium carbonate, soluble with effervescence in nitric acid. If a chloride be present, the *yellow* precipitate caused by silver nitrate will be a mixed one of silver chloride and phosphate, not entirely soluble in the same acid. The salt is incompatible with soluble salts of lime, with which it gives a precipitate of calcium phosphate, and with neutral metallic solutions. It is found in several of the animal secretions, particularly the urine. For an elaborate article upon the methods of determining the percentage of phosphates present in a substance, see *Chem. News*, Oct. 1874, 200.

The medicinal sodium phosphate is one of the three sodium salts of tribasic phosphoric acid, H_3PO_4. In this salt two of the three replaceable hydrogen atoms have been replaced by sodium, so that its formula is HNa_2PO_4, which then crystallizes out with 12 mols. of water. Its complete formula is then $HNa_2PO_4 + 12H_2O$. When gently heated, it loses its water of crystallization; and at a red heat the salt is converted into *sodium pyrophosphate*, $Na_4P_2O_7$. (See *Sodii Pyrophosphas.*)

Medical Properties and Uses. Sodium phosphate was introduced into practice, about the year 1800, by the late Dr. Pearson, of London. In doses of from one to two ounces (31·1–62·2 Gm.) it is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. In smaller doses it has been considerably used, generally in connection with other phosphates, to meet any real or supposed deficiency of phosphates in the system, and for this purpose it is well adapted by its ready solubility. As was first observed by Dr. Wm. Stephenson, of Edinburgh, it has, especially in children, an extraordinary influence upon the hepatic secretion. In infantile cases, with *white or green stools*, with *diarrhœa*, and sometimes with *jaundice*, these evidences of deficient or disordered bile often quickly yield to small doses of sodium phosphate, the passages assuming their healthy yellow color, and the attendant disease generally disappearing. The dose is from three or four to ten grains (0·20 or 0·26–0·65 Gm.) for children, according to the age, and is best administered with their food, especially milk, and may be repeated whenever there is occasion to give food. To adults from twenty to forty grains (1·3–2·6 Gm.) may be given, dissolved in water, after meals. These statements of Dr. Stephenson are confirmed by the experience of Dr. H. C. Wood, at least in regard to children.

SODII PHOSPHAS EFFERVESCENS. Br. Effervescent Sodium Phosphate.

(SŌ'DI-Ī FŌS'FĂS ĔF-FĘR-VĔS'CĘNS.)

Sodæ Phosphas Effervescens; Effervescent Phosphate of Soda.

"Sodium Phosphate, in crystals, 50 *ounces* (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 50 *ounces* (Imp.) or 500 grammes; Tartaric Acid, in powder, 27 *ounces* (Imp.) or 270 grammes; Citric Acid, in powder, 18 *ounces* (Imp.) or 180 grammes. Dry the Sodium Phosphate until it has lost 60 per cent. of its weight; powder the product and mix it with the other ingredients. Place the whole in a dish or pan of suitable form heated to between

200° and 220° F. (93·3° and 104·4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (Imp.) or 1000 grammes." *Br.*

This salt was first introduced in the "Additions" to the British Pharm. 1885; it affords a pleasant method of administering sodium phosphate. Dose, from one-quarter to one-half ounce (7·7–15·5 Gm.).

SODII PYROPHOSPHAS. U. S. Sodium Pyrophosphate.

$Na_4P_2O_7.10H_2O$; 445·24. (SŌ′DI-Ī PĪ-RŌ-PHŎS′PHĂS.) $Na_4P_2O_7.10H_2O$; 446.

This official salt is prepared by heating sodium phosphate in a suitable vessel to redness. When sodium phosphate is subjected to a temperature of 44° C. (111·2° F.), it melts in its water of crystallization; if the heat be increased to 100° C. (212° F.), all the water will be dispelled, and but 40 per cent. of the original weight remain; at 300° C. (572° F.) it is converted into the tetrabasic phosphate or pyrophosphate. By dissolving this residue in water, filtering, and crystallizing, the salt may be obtained.*

Properties. It is officially described as in "colorless, transparent, monoclinic prisms, or a crystalline powder, odorless, and having a cooling, saline, and feebly alkaline taste. Permanent in cool air, slightly efflorescent in warm air. Soluble in 12 parts of water at 15° C. (59° F.), and in 1·1 parts of boiling water; insoluble in alcohol. When heated to 100° C. (212° F.), the salt loses its water of crystallization (40·34 per cent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass. To a non-luminous flame it imparts an intense, yellow color. Its aqueous solution is feebly alkaline to litmus and to phenolphtalein paper. A 5-per-cent. aqueous solution of the salt yields with magnesia mixture a white precipitate; with silver nitrate test-solution it yields a precipitate of a pure white color (distinction from *orthophosphate*), soluble in ammonia water and in nitric acid. With ammonium molybdate test-solution no precipitate is formed within 15 or 20 minutes, even when a gentle heat is applied (distinction from *orthophosphate*). No turbidity or coloration should be produced in the aqueous solution (1 in 20) by the addition of a small quantity of ammonium sulphide test-solution; or of an equal volume of hydrogen sulphide test-solution after the addition of a few drops of hydrochloric acid (absence of *metallic impurities*). If 1 Gm. of the powdered salt be shaken with 3 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), then a small piece of pure tin-foil added, and a gentle heat applied, no brown coloration should appear within fifteen minutes (limit of *arsenic*). If 0·5 Gm. of the salt be dissolved in 6 C.c. of water, and 1 C.c. of sodium bitartrate test-solution then added, the solution should remain perfectly clear (limit of *potassium*). No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of *carbonate*). In the aqueous solution of the salt, rendered acid by nitric acid, not more than a very slight opalescence should be produced by silver nitrate test-solution (limit of *chloride*), or by barium chloride test-solution (limit of *sulphate*)." *U. S.*

Medical Properties. The action of this salt upon the human economy is probably that of the phosphate. It was introduced into the Pharmacopœia on account of its use in the process for ferric pyrophosphate.

SODII SALICYLAS. U. S., Br. Sodium Salicylate.

$NaC_7H_5O_3$; 159·67. (SŌ′DI-Ī SĂL-I-CŸ′LĂS.)

"Sodium Salicylate should be kept in well-stoppered bottles, protected from heat and light." *U. S.* "Sodium Salicylate, $(C_6H_4.OH.COONa)_2,H_2O$, may be obtained by the interaction of salicylic acid and sodium carbonate or sodium hydroxide." *Br.*

This salt was introduced into the U. S. Pharmacopœia at the revision of 1880. It is prepared by mixing 100 parts of pure salicylic acid with sufficient water to form a paste, and then with 104 parts of pure crystallized sodium carbonate (uneffloresced) in a glass or porcelain vessel; carbonic acid gas will be evolved, and sodium salicylate will remain in solution. The liquid may be strained through thoroughly washed muslin, if necessary, and heated in a capsule until the carbonic acid gas is expelled. If alkaline to litmus paper, enough

* This salt has been highly recommended for removing ink-stains from colored cotton fabrics. It is said to remove the stains slowly without affecting the other colors.

salicylic acid must be added to be slightly in excess, and the solution is then evaporated at a low heat to dryness. If the acid be not in excess, the salt will not be white, but gray or lead-colored.*

Properties. Pure sodium salicylate is "a white, amorphous powder, odorless, and having a sweetish, saline taste. Permanent in cool air. Soluble in 0·9 part of water, and in 6 parts of alcohol at 15° C. (59° F.); very soluble in boiling water or alcohol; also soluble in glycerin. When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaves a residue of sodium carbonate. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution slightly reddens blue litmus paper. Ferric chloride test-solution, added to an excess of a concentrated solution of the salt, produces a red precipitate; but when added to a very dilute solution (1 in 100), it produces a deep violet-blue color. If copper sulphate test-solution be added to the aqueous solution (1 in 20), a green color will be produced. On adding to about 0·2 Gm. of the salt, in a test-tube, about 1 C.c. of concentrated sulphuric acid, and then, cautiously, about 1 C.c. of methylic alcohol in drops, on heating the mixture to boiling, the odor of methyl salicylate will be evolved. Hydrochloric or sulphuric acid produces in a concentrated aqueous solution of the salt a voluminous, white precipitate, which, after being separated by filtration, and washed, should conform to the reactions and tests given under *Acidum Salicylicum*. The aqueous solution should be colorless, even when concentrated, and should not effervesce on the addition of acids (absence of *carbonate*). When the solution (1 in 20) is mixed with a small quantity of ammonium sulphide test-solution, or with an equal volume of hydrogen sulphide test-solution, no coloration or turbidity should appear (absence of *metallic impurities*). If 1 Gm. of the salt be dissolved in a mixture of 50 C.c. of alcohol and 25 C.c. of water, then acidulated with nitric acid and filtered, a portion of the filtrate should not be rendered turbid by the addition of a few drops of barium chloride test-solution (absence of *sulphate*). Another portion of the filtrate should remain clear on the addition of a few drops of silver nitrate test-solution (absence of *chloride*). If 1 part of the salt be agitated with 15 parts of cold, concentrated sulphuric acid, no brown color should be produced within fifteen minutes (absence of *readily carbonizable, organic impurities*)." *U. S.* "When heated to redness, the salt evolves inflammable vapors, and a white residue remains which effervesces with acids, and imparts an intense yellow color to flame. *Test-solution of ferric chloride* colors a concentrated solution reddish-brown, and a dilute solution violet. A solution containing not less than 1 per cent. affords a yellowish-brown precipitate with *solution of uranium nitrate* (distinction from carbolates and sulphocarbolates). 50 to 100 grammes kept in a closed vessel for several days should not evolve the faintest smell of phenol. If the aqueous solution be acidulated with *nitric acid* and the precipitate be dissolved by a little *alcohol* (90 per cent.), the mixture affords not more than the slightest reactions with the tests for sulphates or for chlorides. It dissolves without coloration or effervescence in cold *sulphuric acid* (absence of organic impurities and of carbonates)." *Br.* Sodium salicylate is incompatible with antipyrin, forming, when mixed in powder, a liquid mixture.

Medical Properties. The action of sodium salicylate upon the economy, and its therapeutic use, are precisely those of salicylic acid, except that the salt is not locally irritating, and, being soluble, is more rapidly absorbed. When salicylic acid is administered, it is prob-

* Dr. Hager (*N. R.*, Nov. 1879) has furnished the following table, whereby, in the absence of the crystallized sodium salicylate, the salt may be prepared in *solution*, by using the following proportions, in parts by weight, of salicylic acid and sodium bicarbonate.

To make of Sodium Salicylate	Take of		To make of Sodium Salicylate	Take of		To make of Sodium Salicylate	Take of		To make of Sodium Salicylate	Take of	
	Salicylic Acid	Sodium Bicarbonate		Salicylic Acid	Sodium Bicarbonate		Salicylic Acid	Sodium Bicarbonate		Salicylic Acid	Sodium Bicarbonate
4	3·3	2·0	11	9·0	5·5	18	14·7	9·0	25	20·4	12·5
5	4·1	2·5	12	9·8	6·0	19	15·5	9·5	26	21·2	13·0
6	4·9	3·0	13	10·6	6·5	20	16·3	10·0	27	21·11	13·5
7	5·7	3·5	14	11·4	7·0	21	17·2	10·5	28	22·9	14·0
8	6·5	4·0	15	12·2	7·5	22	18·0	11·0	29	23·7	14·5

10	8·2	5·0	17	13·9	8·5	24	19·6	12·0			

ably converted into sodium salicylate as fast as it is taken into the blood. One drachm contains forty-eight grains of the acid. The dose is from fifteen to thirty grains (1–2 Gm.), administered in aromatized solution from three to four times a day.

SODII SULPHAS. U. S., Br. Sodium Sulphate. [Glauber's Salt.]

$Na_2SO_4.10H_2O$; 321·42. (SŌ′DI-Ī SŬL′PHĂS.) $Na_2SO_4.10H_2O$; 322.

"Sodium Sulphate should be kept in well-closed vessels." *U. S.* "Sodium Sulphate, $Na_2SO_4,10H_2O$, may be obtained by the interaction of sodium chloride and other sodium salts with sulphuric acid." *Br.*

Sulphate of Soda; Natrum Sulfuricum, *P. G.;* Sulfas Sodicus (Natricus), Sal mirabile Glauberi; Vitriolated Soda, Glauber's Salt; Sulfate de Soude, Sel de Glauber, *Fr.;* Schwefelsaures Natron, Glaubersalz, *G.;* Sulfato di Soda, *It.;* Sulfato de Soda, Sal de Glaubero, *Sp.*

Sodium sulphate, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad; and it is found combined with calcium sulphate, constituting a distinct mineral. Many ponds containing this salt are found in the country between Santa Fé and the head-waters of the Arkansas, and on the route to the Rocky Mountains. See reference to natural sodium carbonate and sulphate as found in Wyoming. (*Sodii Carbonas*, p. 1241.) A large deposit of Glauber's salt has been found in the Caucasus, not far from Tiflis. It is about ten feet below the surface, and was penetrated five feet, and probably extended much deeper. There are, besides, in the same region, various lakelets containing the same salt in solution. (*N. R.*, Oct. 1872, 151.) As an artificial product, sodium sulphate is formed in the processes for obtaining hydrochloric acid and chlorine, and in the preparation of ammonium chloride from ammonium sulphate and common salt. It may also be procured from sea-water, in which its ingredients are present.

Immense quantities of sodium sulphate are made by decomposing common salt by sulphuric acid, in the manufacture of soda-ash and sodium carbonate (see *Sodii Carbonas*); and, so far from the generated hydrochloric acid being a product of much value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Hydrochloricum.*) MM. Thomas, Dellisse, and Boucard have proposed a new process for preparing sodium sulphate, by double decomposition between sodium chloride and ferrous sulphate. This process avoids the production of hydrochloric acid vapors, and is said to furnish a cheap salt.

The residue of the process for obtaining chlorine by the action of sulphuric acid and manganese dioxide on common salt is a mixture of sodium sulphate and manganous sulphate. Large quantities of this residue are formed in manufacturing chlorinated lime (bleaching powder); and the sodium sulphate in it, roughly purified, supplies a part of the consumption of this salt in making soda-ash and sodium carbonate.

The process for obtaining ammonium chloride from ammonium sulphate and common salt forms another source of sodium sulphate. By double decomposition, sodium sulphate and ammonium chloride are formed; and by exposing the mixed salts to heat, the ammonium chloride sublimes, and the sodium sulphate remains behind. (See *Ammonii Chloridum.*)

Properties. Sodium sulphate is in "large, colorless, transparent, monoclinic prisms, or granular crystals, odorless, and having a bitter, saline taste. The salt effloresces rapidly in the air, and finally loses all its water of crystallization. Soluble, at 15° C. (59° F.), in 2·8 parts of water. The solubility increases up to 34° C. (93·2° F.), when its maximum is attained, 1 part of the salt then dissolving in somewhat less than 0·25 part of water; from thence it gradually decreases with rising temperature, until 1 part requires 0·47 part of boiling water for solution. Insoluble in alcohol; soluble in glycerin. When heated to 33° C. (91·4° F.), the salt fuses, and, on being heated to 100° C. (212° F.), loses all its water (55·9 per cent.). At a red heat the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. A 5-per-cent. aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in nitric acid. If to 5 C.c. of the aqueous solution (1 in 20) 1 C.c. of sodium phosphate test-solution and 0·5 C.c. of ammonia water be added, no turbidity or precipitate should be produced, even after agitation (absence of *magnesium*, etc.). The solution should not effervesce on the addition of an acid (absence of *carbonate*). It should not be colored or rendered turbid by the addition of ammonium sulphide test-solution; or of an equal volume of hydrogen sulphide test-solution, after being acidulated with hydrochloric acid (absence of *arsenic* and

metallic impurities). After acidulation with nitric acid, the aqueous solution should remain clear, or at most be rendered only very slightly opalescent, on the addition of silver nitrate test-solution (limit of *chloride*)." *U. S.* "Soluble in less than half its weight of *water* at temperatures from 77° to 86° F. (25° to 30° C.). Heated to boiling this solution deposits crystals of the anhydrous salt. Insoluble in *alcohol* (90 per cent.). Exposed to heat in a porcelain crucible it loses 55·9 per cent. of water. It affords the reactions characteristic of sodium and of sulphates. Each gramme dissolved in *water* and acidulated with *hydrochloric acid* gives, by the addition of *solution of barium chloride*, a white precipitate, which, when it has been washed and dried, should weigh 0·725 gramme. It should yield no characteristic reaction with the tests for lead, iron, aluminium, calcium, magnesium, potassium, ammonium, or carbonates, and only the slightest reactions with the tests for chlorides." *Br.* When recently prepared it is beautifully transparent; but on exposure to the air it effloresces, and the crystals become covered with an opaque white powder. After long exposure it undergoes complete efflorescence, and falls into powder with loss of more than half its weight. A supersaturated solution of sodium sulphate will remain without crystallizing at ordinary temperatures, even though containing several times the weight of the salt that will be dissolved at the same degree of heat. But the solution instantly forms into a crystalline mass upon adding to it a fragment of the same salt crystallized, or other substances that have been exposed to the air, or upon abruptly placing it in contact with the air. M. D. Gernez appears to have proved that in each instance the cause of crystallization is the same,—namely, sodium sulphate containing ten mols. of water; and where the crystal itself is not added, the result is owing to sodium sulphate existing in the air. (See *A. J. P.*, Sept. 1865, 379.) Subjected to heat, it dissolves in its water of crystallization, then dries, and afterwards by the application of a red heat melts with the loss of 55½ per cent. of its weight. M. Coppet has ascertained that there are two varieties of the anhydrous sulphate,—one in which the salt is deprived of its water at ordinary temperature, the other in which the desiccation is effected at a heat above that of 33° C. (91·4° F.). The two differ in their relation to the crystallization of the salt, the former causing immediate crystallization when thrown into a supersaturated solution, the second not. (*Journ. de Pharm.*, 1874, 36.) Occasionally it contains an excess of acid or alkali, which may be discovered by litmus or turmeric paper. Common salt may be detected by silver nitrate; a salt of iron by potassium ferrocyanide. This salt is not subject to adulteration. It is incompatible with potassium carbonate, calcium chloride, the salts of barium, lead acetate and subacetate, and with silver nitrate if the solutions are strong. It consists of two atoms of sodium combined with the group SO_4 characteristic of sulphates, and crystallized with ten mols. of water, $Na_2SO_4 + 10H_2O$.

Medical Properties and Uses. Sodium sulphate in doses of from half an ounce to an ounce (15·5–31·1 Gm.) is an efficient hydragogue cathartic; in smaller doses, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight in water. Sodium sulphate is much less used than formerly, having been almost entirely superseded by magnesium sulphate, which is less disagreeable to take and milder in its action. Its nauseous taste, however, may be disguised by the admixture of a little lemon-juice or cream of tartar, or by the addition of a few drops of sulphuric acid. It is an ingredient in the artificial Cheltenham salt. (See PART II.) M. D. de Luca has found sodium sulphate remarkably efficient in removing *stains* or *opacity* of the *cornea*, if applied in the form of powdered crystals directly to the eyeball twice daily. (*Journ. de Pharm. et de Chim.*, Sept. 1867.) The only uses of sodium sulphate in the arts are to make sodium carbonate and some kinds of glass. It has no official preparations.

SODII SULPHAS EFFERVESCENS. Br. Effervescent Sodium Sulphate.

(SŌ'DI-Ī SŬL'PHĂS ĔF-FĘR-VĔS'CĘNS.)

Sodæ Sulphas Effervescens; Effervescent Sulphate of Soda.

"Sodium Sulphate, in crystals, 50 *ounces* (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 50 *ounces* (Imp.) or 500 grammes; Tartaric Acid, in powder, 27 *ounces* (Imp.) or 270 grammes; Citric Acid, in powder, 18 *ounces* (Imp.) or 180 grammes. Dry the Sodium Sulphate until it has lost 56 per cent. of its weight; powder the product and mix it with the other ingredients. Place the whole in a dish or pan of suitable form, heated to between 200° and 220° F. (93·3° and 104·4° C.). When the mixture, by aid of careful manipulation of the powder, begins to aggregate, stir it assiduously until it has assumed a granular charac-

ter; then separate it into granules of uniform and convenient size, by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (Imp.) or 1000 grammes." *Br.*

This was a new official preparation of the British Pharm. 1885, having been introduced in the "Additions." It is used as an effervescent laxative, in the dose of from one-quarter to one-half ounce (7·7–15·5 Gm.) dissolved in cold water and taken while effervescing.

SODII SULPHIS. U.S., Br. Sodium Sulphite.

$Na_2SO_3.7H_2O$; 251·58. (SŌ'DI-Ī SŬL'PHĪS.) $Na_2SO_3.7H_2O$; 252.

"Sodium Sulphite should be kept in well-stoppered bottles, in a cool place." *U.S.* "Sodium Sulphite, $Na_2SO_3,7H_2O$, may be obtained by interaction of sulphurous acid and sodium carbonate." *Br.*

Natrum Sulfurosum, Sulfis Sodicus (Natricus); Sulfite de Soude, *Fr.;* Schwefligsaures Natron, *G.*

This salt may be prepared by passing sulphurous acid gas into a solution of sodium carbonate, and evaporating out of contact of the air. The sulphurous acid unites with the soda of the carbonate to form sodium sulphite, and the carbonic acid escapes. After sufficient concentration, the solution is allowed to cool, and the salt crystallizes. A better way, however, is to dissolve a convenient weight of sodium carbonate in a small quantity of water, then pass the sulphurous acid gas through the solution until it is completely saturated, and acid sodium sulphite is formed. The addition of an equal weight of sodium carbonate forms a solution of the neutral sulphite, which is to be evaporated and crystallized. On exposure the salt gradually changes into a sulphate.

Properties. Sodium sulphite is in "colorless, transparent, monoclinic prisms, odorless, and having a cooling, saline, sulphurous taste. In air the salt effloresces, and is slowly oxidized to sulphate. Soluble in 4 parts of water at 15° C. (59° F.), and in 0·9 part of boiling water; sparingly soluble in alcohol. When gently heated, the salt softens somewhat, but does not fuse. Above 100° C. (212° F.) the crystals lose all their water (50 per cent.), without fusing or changing their shape. At a red heat the salt fuses to a reddish-yellow mass of sodium sulphate and sodium sulphide. To a non-luminous flame the salt imparts an intense, yellow color. The aqueous solution is neutral or feebly alkaline to litmus paper. Upon the addition of hydrochloric acid to the salt or its solution, sulphur dioxide gas is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate test-solution and held in the escaping gas; the solution remains clear, no sulphur being separated (distinction from *hyposulphite*). The aqueous solution (1 in 20) should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution, either before or after the addition of ammonia water in slight excess (absence of *metallic impurities*). If a solution of 2·5 Gm. of the salt in 11 C.c. of diluted hydrochloric acid be heated sufficiently to expel the sulphur dioxide, then 0·15 C.c. of barium chloride test-solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If 1·2 Gm. of Sodium Sulphite be dissolved in 10 C.c. of diluted nitric acid, the solution heated to expel the gases, then 0·4 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unchanged by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 0·63 Gm. of the salt be dissolved in 25 C.c. of water recently boiled to expel air, and a little starch test-solution be added, at least 48 C.c. of iodine decinormal volumetric solution should be required to produce a permanent blue tint (each C.c. corresponding to 2 per cent. of the pure salt)." *U.S.* "In colorless transparent monoclinic prisms, efflorescent in dry air, inodorous, with a saline and sulphurous taste. It is readily soluble in *water*, very sparingly in *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of sulphites. The aqueous solution has a neutral or faintly alkaline reaction, and if treated with *hydrochloric acid* evolves sulphurous anhydride, but does not become cloudy (absence of thiosulphate). Each gramme dissolved in 50 cubic centimetres of *water* should decolorize not less than 77·7 nor more than 81·7 cubic centimetres of the *volumetric solution of iodine*." *Br.* Sulphuric acid added to the solution gives rise to a smell of burning sulphur, owing to the escape of sulphurous acid; and the liquid remains transparent, indicating the absence of lime. Sodium sulphite consists of two atoms of sodium combined with the group SO_3, characteristic of sulphites, and crystallized with seven mols. of water, $Na_2SO_3 + 7H_2O$.

Medical Uses. Sodium sulphite has been used in cases of *yeasty vomiting* with remarkable success. The matter vomited in these cases contains two microscopic fungi, called sarcina ventriculi and torula cerevisiæ. The remedy was first used at the suggestion of Prof. Graham, of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Sodium sulphite is sometimes used locally, especially in that species of *aphthous sore mouth* which is attributed to a parasitic vegetable. The wash may be made of a drachm of the salt to a fluidounce of water. It is said that the solution acts with surprising rapidity, a single application of it sometimes removing the disease in 24 hours. Dr. Astrié, an Italian physician, has proposed this salt as a remedy for the constitutional effects of mercury, when used in excess, on the ground that it has the power of rendering the metal soluble. The dose of sodium sulphite is a drachm (3·9 Gm.) three times a day. It has also been largely given internally as an antizymotic (see *Sodii Hyposulphis*), but without general success. According to M. Carey Lea (*Am. Journ. Med. Sci.*, Jan. 1865), it is partially converted in the system into a sulphate and partially escapes with the urine unchanged.

SODII SULPHOCARBOLAS. U. S., Br. Sodium Sulphocarbolate.

[Sodium Paraphenolsulphonate.]

$NaSO_3C_6H_4(OH).2H_2O$; 231·56. $NaC_6H_5SO_4.2H_2O$; 232.

(SŌ′DI-Ī SŬL-PHQ-CĂR′BQ-LĂS.)

"Sodium Sulphocarbolate, or sodium phenol-para-sulphonate, $C_6H_4OH.SO_2ONa.2H_2O$, may be obtained by dissolving phenol in excess of sulphuric acid, and converting the phenolsulphonic acid so obtained into a sodium salt." *Br.*

Sodium Sulphophenate; Sulfophénate de Soude, *Fr.*; Phenylschwefelsaures Natron, *G.*

Sodium sulphocarbolate may be made by mixing equal parts of pure carbolic acid and strong sulphuric acid, whereby *paraphenol sulphonic acid* (sulphocarbolic acid), $C_6H_4(HSO_3)OH$, is produced. The mixed liquids must be subjected to a temperature of 55° C. (131° F.) for several days, and then twenty parts of water should be added. Two parts of barium carbonate are mixed with the liquid, a little at a time, carefully graduating the quantity until effervescence ceases. The liquid is now allowed to stand to permit the precipitation of barium sulphate, and of any carbonate which might be present, and the liquor filtered. The solution of *barium sulphocarbolate* is decomposed by adding sodium carbonate until precipitation ceases, when the liquid is filtered from the barium carbonate, and the sodium sulphocarbolate may be obtained by evaporating the filtrate and crystallizing.

Properties. The U. S. Pharmacopœia describes this salt as in "colorless, transparent, rhombic prisms, odorless, and having a cooling, saline, slightly bitter taste. Somewhat efflorescent in dry air. Soluble, at 15° C. (59° F.), in 4·8 parts of water, and in 132 parts of alcohol; in 0·7 part of boiling water, and in 10 parts of boiling alcohol. When heated a little above 100° C. (212° F.), the salt loses all its water (15·5 per cent.) and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue of sodium sulphate amounting to 30·6 per cent. of the original weight. To a nonluminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. A dilute solution (1 in 100) of the salt is rendered pale violet by ferric chloride test-solution, but remains clear; barium chloride test-solution leaves the solution clear, but if a portion of the salt be ignited, and the residue dissolved in water, the same reagent will produce in the solution a copious, white precipitate. In the aqueous solution (1 in 20) neither hydrogen sulphide test-solution nor ammonium sulphide test-solution should produce any turbidity or coloration (absence of *metallic impurities*); nor should more than a faint opalescence be produced by barium chloride test-solution (limit of *sulphate*), or by silver nitrate test-solution (limit of *chloride*)." *U. S.* "Soluble in 6 parts of *water*, and in 150 parts of *alcohol* (90 per cent.), the solutions being without action on *litmus*. On ignition it gives off phenol, and leaves a residue of sodium sulphate. It imparts an intense yellow color to flame. The dilute aqueous solution is rendered violet by *test-solution of ferric chloride*, does not give a yellowish-brown precipitate with *solution of uranium nitrate* (distinction from salicylate), and should not at once be rendered turbid by *solution of barium chloride* (absence of sulphates)." *Br.*

Medical Properties. The sulphocarbolates have been introduced into medicine with the idea that they would unite the properties of sulphuric and carbolic acids. It is, however, probable that they are inert: future investigations can alone give us positive information.

SPARTEINÆ SULPHAS. U. S. Sparteine Sulphate.

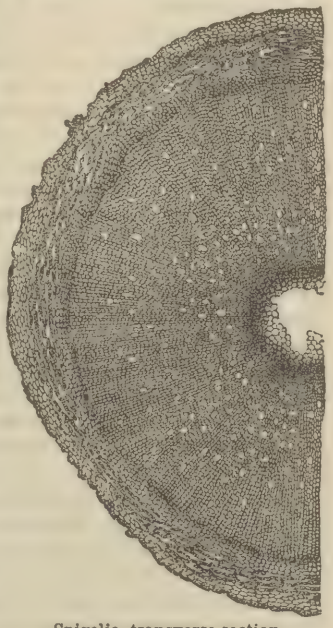
(SPĂR-TĒ-Ī'NÆ SŬL'PHĂS.)

$C_{15}H_{26}N_2H_2SO_4,4H_2O$; 403.23.

"The neutral sulphate of an alkaloid obtained from Scoparius." *U. S.*

This is a new official alkaloidal salt, prepared from Scoparius (see page 1210). It is officially described as in "colorless, white, prismatic crystals, or a granular powder, odorless, and having a slightly saline and somewhat bitter taste. Liable to attract moisture when exposed to damp air. Very soluble in water and alcohol. When heated to about 83° C. (181·4° F.), the salt begins to lose its water of crystallization, all of which escapes at 100° C. (212° F.). At about 136° C. (276·8° F.) it melts, and, upon ignition, it is consumed, leaving no residue. The salt is neutral to litmus paper. If 25 C.c. of ether be added to about 0·1 Gm. of Sparteine Sulphate in a test-tube, then a few drops of dilute ammonia water, so that the latter shall not be in excess, and an ethereal solution of iodine (1 in 50) be afterwards added until the liquid, when shaken, turns from an orange to a dark reddish-brown color, the bottom and sides of the test-tube will after a short time be found coated with minute, dark greenish-brown crystals, distinctly seen with a lens after the liquid has been poured out. On shaking 0·05 Gm. of the salt, in a test-tube, with 5 C.c. of potassium or sodium hydrate test-solution, the liquid will at first be turbid, and small drops of sparteine will gradually collect on the surface. If a strip of moistened red litmus paper be suspended in the mouth of the test-tube, and a gentle heat then applied, the test-paper will gradually acquire a blue color, but no ammoniacal odor should be perceptible (absence of *ammonium salts*)." *U. S.* G. Marque (*Journ. de Pharm. et de Chim.*, xxx. 555) states that if a small quantity of sparteine sulphate be mixed with about one-third of its weight of chromic acid, and gently heated in a porcelain capsule, the mass will soon turn green and emit a strong odor resembling coniine.

For an account of the physiological and therapeutic action of this alkaloid, see *Scoparius*. Dose, from one-sixth to one-half grain (0·011–0·03 Gm.).



SPIGELIA. U. S. Spigelia. [Pinkroot.]

(SPĮ-ĢĒ'LĮ-Ą.)

"The rhizome and rootlets of Spigelia marilandica, Linné (nat. ord. Loganiaceæ)." *U. S.*

Spigélie du Maryland, *Fr.;* Marylandische Spigelie, Spigelie, *G.;* Spigelia, *It.*

Two species of Spigelia have attracted attention as anthelmintics,—*S. anthelmia* of South America and the West Indies, and *S. marilandica* of this country. *S. anthelmia*, L., is an annual of South America and the West Indies, where it is said to be very much used as a powerful and certain anthelmintic. In overdoses it is a powerful poison, which has proved fatal to man, and which not infrequently kills domestic animals.

Spigelia, transverse section.

Spigelia marilandica. L. *Syst. Ed.* (1767) 734; Willd. *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.* i. 142; Barton, *Med. Bot.* ii. 75; *B. & T.* 180. The *Carolina pink* is an herbaceous perennial plant. The stems, several of which rise from the same rhizome, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a one-sided spike, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine color externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the ovary superior, ovate; the style about the length of the corolla, and termi-

nating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the only part recognized in the Pharmacopœias. The drug was formerly collected in Georgia and the neighboring States by the Creek and Cherokee Indians, who disposed of it to the white traders. The whole plant was gathered and dried, and came to us in bales or casks. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and it has now nearly if not quite ceased. The consequence was for a time a great scarcity, and an increase in the price of the drug; but a new source of supply was opened from the Western and Southwestern States, and it is now again plentiful. As we receive spigelia at present, it consists chiefly if not exclusively of the root, without the stems and leaves. We have been informed that most of it comes in casks or bales from St. Louis by the way of New Orleans. That contained in casks is to be preferred, as less liable to be damp and mouldy.

Properties. Pinkroot consists of numerous slender, branching, crooked, wrinkled fibres, from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is brownish or yellowish-brown externally, of a faint, peculiar smell, and a sweetish, slightly bitter, not very disagreeable taste. On microscopic examination the middle layer is seen to be very well developed and the nucleus sheath wanting. It is officially described as "of horizontal growth, about 5 Cm. or more long, 2 or 3 Mm. thick, dark purplish-brown, bent, somewhat branched, on the upper side with cup-shaped scars; on the lower side with numerous, thin, brittle, lighter-colored roots, about 10 Cm. long; the rhizome internally with a whitish wood and a pith which is usually dark-colored or decayed; odor somewhat aromatic, taste sweetish, bitter and pungent. It should not be confounded with the underground portion of *Phlox Carolina* Linné (nat. ord. *Polemoniaceæ*), the roots of which are brownish-yellow, rather coarse, straight, and contain a straw-colored wood underneath a readily removable bark." *U. S.*

The virtues of spigelia are extracted by boiling water. The root, analyzed by M. Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassium and calcium, etc., and woody fibre. The principle upon which the virtues of the root are thought to depend is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication. An analysis of the root by Dr. R. H. Stabler yielded as results a bitter uncrystallizable principle upon which the virtues of the medicine are supposed to depend, a little volatile oil, tannic acid, inert extractive, wax, resin, lignin, and salts of soda, potassa, and lime. Stabler finds that the active principle is acrid and bitter, soluble in water and alcohol, insoluble in ether, not volatilizable without change, uncrystallizable, neutral, and deliquescent. W. L. Dudley (*Am. Chem. Journ.*, vol. i. p. 150), on the contrary, finds that the active principle of spigelia is a volatile alkaloid. He gets it by distilling the ground root with milk of lime over a paraffin bath, and collecting the distillate in hydrochloric acid. After evaporation to dryness, the residue is taken up with alcohol and crystallized out of solution. He compares the reactions of this alkaloid, which he calls *spigeline*, with those of nicotine, coniine, and lobeline. Spigeline yields a brownish-red precipitate with a solution of iodine in potassium iodide, a white crystalline precipitate with potassio-mercuric iodide, and a white flocculent precipitate with metatungstic acid. Boorsma (*P. J. Tr.*, 1898, 89) found 0·0005 Gm. of *spigeline* to be lethal to guinea-pigs.

The stalks of the dried plant are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish color, and an odor somewhat like that of tea. In taste they resemble the root, and they afforded to M. Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from the shops, as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they were both employed. The roots are sometimes mixed with those of other plants, particularly of a small vine which twines round the stem of the Spigelia. These are long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter-colored than the pinkroot. They should be separated before the latter is used. It is said to be adulterated with a product called in the markets *East Tennessee pinkroot*, the botanical origin of which is unknown. (*A. J. P.*, 1875, p. 134.) The root of *Phlox carolina* is occasionally em-

ployed as an adulterant for spigelia. The rhizome is smoother and lacks the cup-shaped scars so characteristic of true spigelia, having also frequently the lower portion of the stem still attached; whilst the rootlets are straighter, thicker, and less wiry than those of spigelia. According to Henry G. Greenish, *Phlox root* can at once be separated microscopically from spigelia root by the presence in it of numerous stone-cells, and also of cells more or less completely filled by granular cystoliths. (*P. J. Tr.*, xxi.) The activity of spigelia is somewhat diminished by time.

Medical Properties and Uses. Spigelia is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it is said to cause vertigo, dimness of vision, dilated pupils, spasms of the facial muscles and of the eyelids, and even general convulsions. The death of two children who expired in convulsions was attributed to it by Dr. Chalmers. Dr. H. A. Hare (*Med. News*, March, 1887) has found that in the lower animals it produces symptoms similar to those just described, namely, dilatation of the pupil, exophthalmia, strabismus, progressive muscular weakness of spinal origin, cardiac depression, and death from failure of respiration. The narcotic effects are said to be less apt to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, in both regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia, first learned from the Cherokee Indians, were made known to the medical profession by Drs. Lining, Garden, and Chalmers, of South Carolina.

It may be given in substance or infusion. The dose of the powdered root for a child three or four years old is from ten to twenty grains (0·65–1·3 Gm.), for an adult from one to two drachms (3·9–7·8 Gm.), to be repeated morning and evening for several days successively, and then followed by a brisk cathartic. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is a more common form of administration. It may be made by infusing half a troy-ounce of the root in a pint of boiling water. It is usually combined with senna or some other cathartic, to insure its action on the bowels. A preparation much sold under the name of *worm tea* consists of spigelia, senna, manna, and savine, mixed together, in various proportions, to suit the views of different individuals. Spigelia is also very often given in the form of fluid extract.

SPIRITUS. Spirits.

(SPĬR'Ị-TŬS.)

Alcoolats, *Fr.*; Geiste, *G.*

Spirits, as the term is here used, are alcoholic solutions of volatile principles formerly in general procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapor of alcohol and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ diluted alcohol or proof spirit, with the water of which the oil comes over in the latter part of the process. As the proof spirit of commerce is often impregnated with foreign matters, which give it an unpleasant flavor, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the color and empyreumatic flavor arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and, as a rule, the heat should be applied by means of a water-bath, or of steam. The aromatic should be macerated for some days with the alcohol before being submitted to distillation, as the oil, being thus dissolved, rises more readily with the spirituous vapor than when confined in the tissue.

The aromatic spirits are used chiefly to impart a pleasant odor and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in *flatulent colic*, and as agreeable stimulants in *debility of the stomach.*

The U. S. P. 1890 added to the list *Spiritus Amygdalæ Amaræ*, *Spiritus Aurantii Compositus*, *Spiritus Glonoini*, and *Spiritus Phosphori*, the Br. Pharm. 1898, *Spiritus Anisi.*

SPIRITUS ÆTHERIS. U. S., Br. Spirit of Ether.

(SPĬR'Ị-TŬS Æ'THẸ-RĬS.)

Spiritus Æthereus, s. Liquor Anodynus Mineralis Hoffmanni, *P. G.;* Ether hydrique (sulfurique) alcoolisé, Liqueur anodine d'Hoffmann, *Fr.;* Hoffmann'sche Tropfen, *G.*

"Ether, *three hundred and twenty-five cubic centimeters* [or 10 fluidounces, 475 minims]; Alcohol, *six hundred and seventy-five cubic centimeters* [or 22 fluidounces, 396 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Ether, 10 *fl. ounces* (Imperial measure) or 500 cubic centimetres; Alcohol (90 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Mix." *Br.*

This preparation is merely ether diluted with twice its volume of alcohol. Although introduced into the U. S. P. 1880, it does not seem to have been employed to any extent, and it might have been dropped with advantage at the 1890 revision. The corresponding preparation of the German Pharmacopœia contains less ether, being made of one part of ether to three parts of alcohol, both by weight. Prepared with materials of proper strength, its sp. gr. is 0·806 to 0·811. *Br.* Its medical properties are similar to those of ether. The dose is from one to three fluidrachms (3·75–11·25 C.c.), properly diluted with sweetened water.

SPIRITUS ÆTHERIS COMPOSITUS. U. S., Br. Compound Spirit of Ether. [Hoffmann's Anodyne.]

(SPĬR'Ị-TŬS Æ'THẸ-RĬS CỌM-PŌṢ'Ị-TŬS.)

Liqueur Nervine de Bang, *Fr.;* Zusammengesetzter Aetherweingeist, *G.*

"Ether, *three hundred and twenty-five cubic centimeters* [or 10 fluidounces, 475 minims]; Alcohol, *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims]; Ethereal Oil, *twenty-five cubic centimeters* [or 406 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. *U. S.*

"Ether, 5½ *fl. ounces* (Imperial measure) or 137·5 cubic centimetres; Alcohol (90 per cent.), 78 *fl. ounces* (Imp. meas.) or 1950 cubic centimetres; Sulphuric Acid, 36 *fl. ounces* (Imp. meas.) or 900 cubic centimetres; Distilled Water, 1½ *fl. ounces* (Imp. meas.) or 37·5 cubic centimetres; Sodium Bicarbonate, *a sufficient quantity.* Gradually mix the Sulphuric Acid with *forty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Alcohol; let the mixture stand for twenty-four hours. Then distil slowly until a thermometer, the bulb of which is within the liquid, indicates a temperature of 341° F. (171·6° C.). Pour the distillate into a separator, and, after separation is complete, remove the lower layer. Add the Distilled Water to the upper layer, and also, gradually, Sodium Bicarbonate, until, after agitation, the liquid is nearly neutral to *litmus paper.* Separate the ethereal liquid, and add to it the Ether and *thirty-eight fluid ounces* (Imp. meas.) or nine hundred and fifty cubic centimetres of the Alcohol. Filter." *Br.*

This preparation is an alcoholic solution of ether, impregnated with heavy oil of wine. In the U. S. formula, determinate quantities of ether, alcohol, and oil are taken, the ether having half the volume of the alcohol. The formula of the U. S. P. 1890 is practically the same as that of the U. S. P. 1880. In the last revision of the British Pharmacopœia this preparation was improved according to the suggestions of W. Inglis Clark (*P. J. Tr.*, 1896, 183); but the process still yields an uncertain product, containing ether, alcohol, and a trace of oil of wine.

Compound spirit of ether is a colorless, volatile liquid, having a burning, slightly sweetish taste, and the peculiar odor of ethereal oil. If it have an empyreumatic odor, it has been badly prepared. Its sp. gr. is 0·815, according to the U. S. Pharmacopœia of 1870; the present official preparation contains a little less oil of wine. When pure, it is wholly volatilized by heat, and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of ether by the addition of various fixed oils. This sophistication may be detected by mixing the suspected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are fixed oil, the greasy stain will remain; if ethereal oil, the stain will disappear. When fixed oils are used to adulterate this preparation, the milkiness is generally too great, and not like the translucent, leaden milkiness of the genuine article. (Squibb.) "A colorless mobile liquid with characteristic ethereal odor and taste. Specific gravity 0·808 to 0·812. It gives an opalescent solution when mixed with twice its volume of *water.* 2 or 3 cubic centimetres evaporated spontaneously on a watch-glass should not yield a residue having an unpleasant odor (absence of empyreumatic impurities)." *Br.*

It is much to be regretted that our manufacturing chemists do not follow the Pharmacopœia in making Hoffmann's anodyne. In rectifying crude ether, the distillation is continued as long as the ether comes over of the proper specific gravity; after which the manufacturer has been in the habit of changing the receiver and obtaining an additional distillate, consisting of ether and alcohol, impregnated with a little ethereal oil. Now, it is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, smell, opalescence, etc., to a standard preparation, kept by the manufacturer, that is sold as Hoffmann's anodyne. Nothing could be more uncertain in its results than a proceeding like this; and we cannot be surprised that the medicine as obtained from different apothecaries varies very much in properties, and often disappoints the expectations of the physician. The chief excuse for the departure from the official directions is the costliness of the ethereal oil; but, even were this much greater than it really is, the excuse would not be valid; and it cannot be justified, on any principle of morality, to sell under the official title a preparation which has no claim to it whatever.

Medical Properties. This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles when properly prepared. In addition to the stimulating and antispasmodic qualities of ether which it contains, it possesses anodyne properties, highly useful in *nervous irritation* and in want of sleep from this cause. These additional virtues are probably derived from the official oil of wine, which the late Drs. Physick and Dewees found, dissolved in alcohol, very efficacious in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed, are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil. This preparation is on many occasions a useful adjunct to laudanum, to prevent *nausea*. The dose is from thirty minims to two fluidrachms (1·85–7·5 C.c.), given in sweetened water.

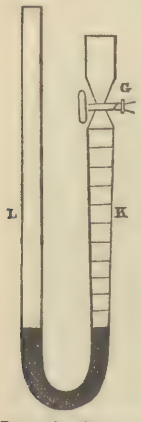
SPIRITUS ÆTHERIS NITROSI. U. S., Br. Spirit of Nitrous Ether.

(SPĬR'Ĭ-TŬS Æ'THĘ-RĬS NĪ-TRŌ'SĪ.)

"An alcoholic solution of Ethyl Nitrite [$C_2H_5NO_2 = 74·87$], yielding, when freshly prepared, and tested in a nitrometer, not less than 11 times its own volume of Nitrogen Dioxide [$NO = 29·97$]." *U. S.* "An alcoholic solution containing ethyl nitrite, aldehyde, and other substances." *Br.*

Spiritus Nitri Dulcis, *Br.;* Sweet Spirit of Nitre; Spiritus Ætheris Nitrici; Spiritus Nitrico-æthereus; Ether azoteux alcoolisé, Liqueur anodine nitreuse, *Fr.;* Versüsster Salpetergeist, *G.*

"Sodium Nitrite, *six hundred and thirty-five grammes** [or 22 ounces av., 175 grains]; Sulphuric Acid, *five hundred and twenty grammes* [or 18 ounces av., 150 grains]; Sodium Carbonate, *ten grammes* [or 154 grains]; Potassium Carbonate, completely deprived of water by drying, *thirty grammes* [or 1 ounce av., 25 grains]; Deodorized Alcohol, Water, each, *a sufficient quantity.* Dissolve the Sodium Nitrite in *one thousand cubic centimeters* [or 33 fluidounces, 391 minims] of Water, and put the solution into a suitable flask, connected with a condenser kept cold by ice-cold water; then add *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims] of Deodorized Alcohol, and mix well. Through a cork fitted into the mouth of the flask insert a funnel-tube dipping below the surface of the liquid. With the condenser connect a receiver, and keep this surrounded by a mixture of common salt and crushed ice. Then gradually introduce into the flask, through the funnel-tube, the Sulphuric Acid previously diluted with *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Water. Distillation will usually commence before the whole of the Acid has been added. When all the Acid has been introduced, regulate the distillation by the application or withdrawal of a gentle heat until no more nitrous ether distils over. Wash the distillate, first, with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of ice-cold Water to remove any alcohol which may have passed over, and then remove any traces of acid by washing the Ether with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of ice-cold Water, in which the Sodium Carbonate had previously been dissolved. Carefully separate the Ether from the aqueous liquid, and agitate it, in a well-stoppered vial, with the Potassium Carbonate to remove traces of water. Then filter it through a pellet of cotton, in a covered funnel, into a tared bottle containing *two thousand cubic centimeters* [or 67 fluidounces, 302 minims] of Deodorized Alcohol. Ascertain the weight of the Nitrous Ether filtered into the Alcohol by noting the increase of weight of the tared bottle and contents, and then add enough Deodorized Alcohol to make



* The quantity stated in the first copies of the U. S. P. 1890—*i.e., seven hundred and seventy grammes*—was erroneous; it should be *six hundred and thirty-five grammes.* (See *Proc. A. P. A.*, 1894, 236.)

the mixture weigh *twenty-two times* the weight of the Nitrous Ether added. Lastly, transfer the product to small, dark amber-colored, well-stoppered vials, and keep them in a cool place, remote from lights or fire." *U. S.*

"Nitric Acid, 3 *fl. ounces* (Imperial measure) or 150 cubic centimetres; Sulphuric Acid, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Copper, 2 *ounces* (Imp.) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity*. To *one pint* (Imp. meas.) or one thousand cubic centimetres of the Alcohol add gradually the Sulphuric Acid, stirring them together; then stir in *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Nitric Acid; the mixture being made in a retort or flask, in which the copper has been placed, and to which a thermometer is fitted; attach to the retort or flask an efficient condenser and receiver, the latter containing *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Alcohol, and, applying heat gently, distil at a temperature commencing at 170° F. (76·7° C.), and rising to 175° F. (79·4° C.), but not exceeding 180° F. (82·2° C.), until the volume of liquid in the receiver has been increased to *thirty-two fluid ounces* (Imp. meas.) or to sixteen hundred cubic centimetres, the receiver and the condenser being kept cool with ice-cold water. Then withdraw the source of heat, and having allowed the contents of the retort to cool, introduce the remaining *half-ounce* (Imp. meas.) or twenty-five cubic centimetres of Nitric Acid, and resume the distillation as before, until the liquid in the receiver has been increased to *thirty-four fluid ounces* (Imp. meas.) or seventeen hundred cubic centimetres. Mix this liquid with *one pint* (Imp. meas.) or one thousand cubic centimetres of the Alcohol, or with as much as will make the product contain 2½ per cent. of ethyl nitrite when tested as described in the following paragraph. Preserve the Spirit of Nitrous Ether in well-closed vessels; preferably in a cool dark place, and in small bottles." *Br.*

NITROGEN DIOXIDE TEST.

"1 volume agitated briskly at intervals during 5 minutes in a brine-charged nitrometer, with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid*, should yield, at the normal temperature (60° F. or 15·5° C.) and pressure (30 inches or 760 millimetres of mercury), and when freshly prepared, at least 6¼, but not more than 7, volumes of nitric oxide gas, corresponding to at least 2½ parts by weight of ethyl nitrite in 100 parts by weight of the Spirit; and even after it has been kept for some time, and the vessel containing it has occasionally been opened, it should yield not much less than 5 times its volume of the gas, corresponding to nearly 2 per cent. by weight of ethyl nitrite or a minimum of 1¾ per cent." *Br.* The U. S. P. 1890 and the Br. Ph. 1898 quantitative test is based on Allen's method, differing only in the relative quantities of the reagents. (See p. 1274; also paper by Dr. C. O. Curtman, *Proc. Missouri Pharm. Association*, July, 1892, and *A. J. P.* 1898, 273.)

Lunge's nitrometer.

Allen's Test for Ethyl Nitrite. A nitrometer* (see cut) should be filled with strong brine, and 5 C.c. of the sample to be tested should be placed in the cup of the nitrometer, and allowed to enter through the tap, taking care that no air gets in at the same time. Five C.c. of a strong solution of potassium iodide is next allowed to enter, and this is followed by about 5 C.c. of dilute sulphuric acid. Effervescence immediately ensues, and, if the tube be vigorously agitated at intervals, the reaction will be complete in five minutes, when the level of the liquid in the two limbs of the nitrometer is adjusted, and the volume of nitrogen dioxide gas read off. If the volume of gas evolved be small, another 5 C.c. of the sample should be let into the nitrometer, and the agitation repeated. The calculation is the same as in Eykman's process, the reaction being

$$(C_2H_5)NO_2 + KI + H_2SO_4 = (C_2H_5)OH + KHSO_4 + I + NO.$$

When strictly accurate results are not required, the volume of gas need not be corrected for variations of pressure, temperature, and tension of aqueous vapor, and if these considerations be omitted the calculation will be much simplified. Thus, if 0·030 gramme of nitrogen dioxide (representing 0·075 gramme of $C_2H_5NO_2$) under the *ordinary* conditions of pressure and temperature be taken to measure 23·55 C.c., then

$$\frac{\text{volume of gas in C.c.} \times 0{\cdot}3185}{\text{measure of sample in C.c.} \times \text{density of sample}} = \text{percentage by weight of } C_2H_5NO_2.$$

* For a simpler form of nitrometer, see *P. J. Tr.*, 1887, p. 763, or *Proc. A. P. A.*, 1887, p. 19; also *Ephemeris*, 1889, p. 1202.

If the density of the sample be omitted from the equation, the result will be the number of grammes of ethyl nitrite per 100 C.c. of the sample.

The nitrometer method has been proved to give very good results with pure sodium nitrite (prepared from silver nitrite) employed in known amount. The results with spirit of nitrous ether are somewhat higher than those given by Eykman's method, the difference being least when sodium chloride is employed in the latter process and time is given for the ferrous solution to react thoroughly on the solution of ethyl nitrite. The results by the iodide method are almost certainly more accurate than those by Eykman's process. With most specimens of sweet spirit of nitre a considerable amount of nitric oxide is produced (and iodine liberated) before adding the acid, the reaction probably depending on the presence of free acid in the sample. The results obtained in the nitrometer are remarkably constant, and the method furnishes a very easy means of assaying sweet spirit of nitre with considerable accuracy, which is further increased if a correction of 1·5 C.c. (= 0·0048 gramme of $C_2H_5NO_2$) be made for solubility of the gas. The process has the advantage of great ease and rapidity, and actually measures the nitrous compounds present in the sample, instead of leaving their proportions to be inferred from a more or less complex reaction, such as the reduction of permanganate, etc.

The official spirit of nitrous ether is a mixture of nitrous ether or ethyl nitrite, $C_2H_5NO_2$, and alcohol (rectified spirit). For many years, spirit of nitrous ether has been made by acting on alcohol with nitric acid, and the present British process and that of the U. S. P. 1880 are constructed on this plan. The U. S. P. 1890 process differs essentially: in it, the use of nitric acid is abandoned, sodium nitrite being substituted as the source of the nitrous compound (see page 1255). Nitrous ether is always generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. In the U. S. Pharmacopœia of 1850 the requisite nitric acid was obtained by using the materials for generating it, namely, potassium nitrate and sulphuric acid; for details of the process, see U. S. D., 14th ed., p. 1445.

In the U. S. 1860 process, which was modelled after the plan of Squibb, the nitric acid and alcohol were directly mixed in a retort. The liquid condensed in the receiver was mixed with potassium carbonate, and again distilled, in order to free it from the acid which had come over with the nitrous ether, and, being too strong with ether to meet the purposes required, was diluted with alcohol, and thus brought to the state of *spirit* of nitrous ether. It was a great improvement over the formula of earlier Pharmacopœias, and had the merit of insuring a preparation of definite strength. But in the Pharmacopœia of 1870 the British process was substituted, as even better than it.

The U. S. 1880 process differed in several particulars from those formerly official. Copper was no longer used. The use of this metal originated with Prof. Redwood, under the impression that the nitrous radical was liberated by it and enabled to unite more readily with the ethyl of the alcohol, to form ethyl nitrite. Our experience is that upon the small scale the copper served a useful purpose in controlling and moderating the reaction, but excellent results have been obtained by substituting broken glass, and we have obtained quite as large a yield of the peculiar ether when the copper was omitted. The nitric acid was not added in two portions, but the whole quantity was mixed with the sulphuric acid and alcohol at first. This was an improvement, in our opinion. The direction to "heat rapidly, by means of a water-bath, until strong reaction occurs and the temperature reaches 80° C. (176° F.)," was apt to cause loss in the hands of the inexperienced through excessive action, and inability to condense all the vapor of ethyl nitrite which would be suddenly generated. A temperature of 72° C. (161·6° F.), in our experience, was amply sufficient to start the reaction, and as soon as effervescence took place the heat should have been *at once removed*, and not reapplied until the reaction slackened, so that a uniform and not an excessive reaction might be maintained. The greatest change was, however, in purifying the distillate by agitating it with ice-cold distilled water, separating the ethereal layer and mixing it with alcohol, so that the finished product should contain 5 per cent. by weight of the crude ethyl nitrite. It is very doubtful, in our opinion, whether anything was removed by the agitation with cold water except some of the alcohol. As aldehyde and hydrocyanic acid are both soluble in ethyl nitrite, and as alcohol must be added subsequently, the advantage of the separation of the nitrous ether in this way was not very apparent, and when it is considered that ethyl nitrite is soluble in water and more soluble in alcohol, some of the most valuable portion of the distillate must have been wasted by being dissolved in the cold water. A thoroughly effective method of separating ethyl

nitrite from its solution in alcohol and water is yet to be discovered. Some manufacturers agitate the distillate with a saturated solution of calcium chloride to separate the ethyl nitrite, and the British Pharmacopœia once used this method as a test.*

The U. S. P. 1890 process overcomes these objections by generating the nitrous compound necessary to effect the combination with ethyl by acting on sodium nitrite with sulphuric acid in the presence of alcohol, the violence of the reaction being controlled by diluting both the sulphuric acid and the alcohol with water, and by using an aqueous solution of the nitrite. A very thorough means of refrigeration must be used, on account of the extreme volatility of the distillate, and because evolution of ethyl nitrite commences before all the sulphuric acid is added and without the use of any other heat than that generated by the chemical reaction. Heat should not be applied until the reaction becomes slower, and then only a very moderate heat (capable of being instantly withdrawn if necessary) applied. The advantages of the new process are that the production of aldehyde and acetic ether is avoided, through the absence of nitric acid, and pure ethyl nitrite is easily obtained. Sodium nitrite can be procured of standard purity, although the impurities in the commercial salt do not affect the character of the ethyl nitrite. The use of alkaline nitrites in making ethyl nitrite is not new, as both potassium and sodium nitrites have been employed, Feldhaus, Dunstan, Dymond,† and others having published processes; Dr. Frerichs, of St. Louis, has used the method on a large scale; and Prof. C. O. Curtman and E. L. Patch, of Boston, also recommend its employment. See *Amer. Druggist*, 1893, p. 171.

The present British formula rejects the sodium nitrite process, but introduces under *Liquor Ethyl Nitritis* (see p. 796) a solution made by decomposing sodium nitrite in the presence of alcohol, and diluting the ethyl nitrite produced, with alcohol containing a little glycerin. It is unfortunate that both preparations were not made of the same strength, the solution containing 3 per cent., the spirit only 2 per cent., of ethyl nitrite; the solution contains no aldehyde, but the spirit is permitted to contain aldehyde and other substances.

Theory of the Production of Nitrous Ether, etc. The reaction in the U. S. P. 1890 process may be expressed as follows: $2C_2H_5OH + 2NaNO_2 + H_2SO_4 = 2C_2H_5NO_2 + Na_2SO_4 + 2H_2O$. Alcohol, sodium nitrite, and sulphuric acid when brought in contact yield ethyl nitrite, sodium sulphate, and water. The nitric acid process may be explained as follows. One mol. of nitric acid, by reacting with one mol. of alcohol, forms one mol. of nitrous acid, one mol. of *aldehyde*, and one mol. of water: thus, $HNO_3 + C_2H_6O = HNO_2 + C_2H_4O + H_2O$. The nitrous acid, as soon as formed, reacts with a second mol. of alcohol, so as to form one mol. of nitrous ether or ethyl nitrite, with separation of one mol. of water, according to the reaction $C_2H_5.OH + HNO_2 = C_2H_5NO_2 + H_2O$. It has, however, been shown by Dr. Golding Bird that, when an excess of alcohol is used, *saccharic acid* is first formed, and that, when the formation of the nitrous ether has nearly ceased, aldehyde appears in the distilled product, and simultaneously oxalic acid in the contents of the retort, before which time the latter cannot be discovered. All these products result from the oxidizing action of the

* R. F. Fairthorne has prepared Spirit of Nitrous Ether without the use of a retort or still. (*A. J. P.*, 1880, p. 7; see also method by Mr. Emlen Painter, *Proc. A. P. A.*, 1884–1886.)

† *Ethyl Nitrite. Expeditious Method of Preparing the Pure Ether.* Professor Dunstan and Mr. T. S. Dymond find the following method to be admirably adapted to the production of pure nitrous ether in the nearly theoretical quantity without the use of heat, the ether, in the absence of excess of acid, being easily separated without distillation. A solution is made by dissolving 34·5 grammes of sodium nitrite in water. The liquid is diluted to 120 C.c. and cooled below 0° C. by surrounding the vessel which contains it with a mixture of ice and salt. The sodium nitrite of commerce contains from 95 to 98 per cent. of nitrite, and therefore a quantity corresponding to the pure salt must be taken. A slight excess of the salt does not interfere with the reaction. 13·5 C.c. of sulphuric acid are added to a cooled mixture of 32 C.c. of alcohol, with an equal volume of water; the liquid is then diluted to 120 C.c. and cooled below 0° C. This acid liquid is allowed to pass gradually through a thistle funnel with constant stirring to the bottom of the solution of sodium nitrite, contained in a long narrow glass vessel surrounded by ice and salt. The addition of the whole of the acid liquid occupies only a few minutes, and at its conclusion a pale-yellow layer of ethyl nitrite is found to be completely separated from the lower layer of solution of sodium sulphate, which is semi-solid from the separation of crystals of the salt. The ethyl nitrite so formed contains only traces of alcohol and water, the first being removed by agitation with cold water, the second by digestion with recently ignited anhydrous potassium carbonate. The yield is from 30 to 35 grammes; the calculated yield is 37·5. It cannot be preserved under ordinary conditions without decomposition, but if kept in contact with fragments of anhydrous potassium carbonate in a closely stoppered bottle it may be kept for a long time without change. It boils at 17·5° C., and possesses at 0° C. the sp. gr. 0·917–0·920 (water at 0° C. = 1). Analysis proves it to be nearly absolutely pure ethyl nitrite. The authors recommend for medicinal use a 2-per-cent. *solution of ethyl nitrite* in absolute alcohol. Its stability might be increased by the addition of 5 per cent. of glycerin; but even this is prone to change, though not so much as the solution in absolute alcohol simply, while the solution in rectified spirit changes to a still greater extent. The solution intended to be administered should not be diluted with water until just before it is to be taken. (*P. J. Tr.*, 1888, 861–863.)

nitric acid upon the alcohol, increasing the proportion of oxygen in the substances formed, either by removing the hydrogen, or by abstracting this element and adding oxygen at the same time.

In the process of the British Pharmacopœia the nitric acid is converted into nitrous acid by the reducing action of metallic copper and sulphuric acid, the reaction being $HNO_3 + Cu + H_2SO_4 = HNO_2 + CuSO_4 + H_2O$. The nitrous acid now reacts with the alcohol as in the previous reaction, so as to produce the nitrous ether. The object of using the sulphuric acid is to economize the nitric acid.

Properties of Ethyl Nitrite. *Pure* ethyl nitrite is pale yellow, has the smell of apples and Hungary wine, boils at 18° C. (64·4° F.), and has the sp. gr. 0·900 at 15·5° C. The density of its vapor is 2·627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassa, potassium hyponitrite and alcohol are formed, without producing a brown color, showing the absence of aldehyde. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The *impure* ether, as formerly obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boiled at 21·1° C. (70° F.), and had the density of 0·886 at 4·4° C. (40° F.). The specific gravity assigned to it by the Edinburgh College was 0·899. Mixed with an alcoholic solution of potassa, it became dark brown, with production of *aldehyde resin*. This discoloration showed the presence of aldehyde. When kept, it became acid in a short time, as shown by litmus; and nitric oxide was given off, which often caused the bursting of the bottle. Its tendency to become acid was rendered greater by the action of the air, and depended on the absorption of oxygen by the aldehyde, which thereby became acetic acid. Mr. Harvey, of Leeds, has suggested the use of pure crystals of potassium bicarbonate in a bottle in order to prevent the development of an acid reaction. Dr. J. C. Rademacher has found that the crystals after a time are partially converted into a nitrate. (*A. J. P.*, xlii. 106.) These facts evince the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Nitrous ether is formed by the combination of one mol. of nitrous acid and one of ethyl, and its formula is $C_2H_5.NO_2$. It was, therefore, improperly called *nitric ether*. Considered as a salt, its proper name is *ethyl nitrite*. In its pure and concentrated state it is never used in medicine. (See *Liquor Ethyl Nitritis*, p. 796.)

Properties of Spirit of Nitrous Ether. This is "a clear, mobile, volatile, and inflammable liquid of a pale yellowish or faintly greenish-yellow tint, having a fragrant, ethereal, and pungent odor free from acridity, and a sharp, burning taste. Specific gravity, about 0·820 at 15° C. (59° F.). When freshly prepared, or even after being kept for some time with but little exposure to light and air, it is neutral to litmus paper. When long kept, or after having been freely exposed to air and light, it acquires an acid reaction, but it should not effervesce when a crystal of potassium bicarbonate is dropped into it." *U. S.* "A limpid liquid, having a very faint yellowish tinge, inflammable, of a peculiar penetrating apple-like odor, and a characteristic taste. Specific gravity 0·838 to 0·842. When Spirit of Nitrous Ether is carefully poured on an acidulated strong solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. 10 cubic centimetres, mixed with 5 cubic centimetres of the *volumetric solution of sodium hydroxide* and 5 cubic centimetres of *water*, should assume a yellow color, which should not become brown on standing 12 hours (limit of aldehyde). It should not effervesce, or only very feebly, when shaken with *sodium bicarbonate* (limit of acid"). *Br.* It keeps well in half-pint bottles, securely stopped with waxed glass stoppers, and covered with dark paper, as Squibb proved by examining some bottles thus put up, after the lapse of two years. When exposed it is apt to become acid with age. Sweet spirit of nitre mixes with water and alcohol in all proportions. It is very inflammable, and burns with a whitish flame.

Impurities and Tests. Sweet spirit of nitre, when made by the nitric acid process, is never quite free from aldehyde, and, if the distillation be too long continued, it is apt to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyde, if in considerable proportion, may be detected by its imparting a pungent odor and an acrid flavor, and by the preparation assuming a brown tint on the addition of a weak solution of potash, owing to the formation of aldehyde resin (see official test, page 1274). Another test for aldehyde, though less reliable, is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample be good, the change of color will be slight, and the mixture will be considerably viscid;

if it contain much aldehyde, it will become dark-colored. If water or spirit be present in undue proportion, the viscidity will be less. (*Phillips.*) Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. Nitrogen acids are known by their coloring blue a piece of paper previously dipped into tincture of guaiac. These acids operate injuriously by their chemical reactions with other substances, when spirit of nitre is prescribed in mixtures. Thus, they liberate iodine from potassium iodide, gradually decolorize compound infusion of rose, and in the compound mixture of iron hasten the conversion of ferrous oxide into ferric oxide. To obviate these effects, Mr. Harvey, of Leeds, keeps sweet spirit of nitre standing on crystals of potassium bicarbonate, and states that, if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*P. J. Tr.*, Jan. 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time; but, according to M. Klauer, when rectified from neutral potassium tartrate it continues unchanged for months. A deep olive color with ferrous sulphate shows the presence of a nitrogen oxide or acid.

According to Mr. Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from nitrous ether formed by impregnating alcohol with nitrous acid evolved by the action of starch on nitric acid, according to the process of Liebig. In making sweet spirit of nitre on a large scale, Dr. Squibb found that hydrocyanic acid vapors were produced if the heat happened to rise too high, and the ether ceased to be formed. Dr. Schoor and G. B. Schmidt found that, after a careful distillation, hydrocyanic acid could be detected in the residue left in the retort to the amount of 0·977 per cent., whilst the distillate contained but an insignificant trace. (*Pharm. Zeitung*, No. 37; *N. R.*, Sept. 1880.)

Alcohol and water are often fraudulently added to sweet spirit of nitre. These additions are difficult to detect. The official tests are as follows: "If a test-tube be half filled with the Spirit, and put into a water-bath heated to 65° C. (149° F.) until it has acquired this temperature, the Spirit should boil distinctly upon the addition of a few small pieces of broken glass. If 10 C.c. of the Spirit be mixed with 5 C.c. of potassium hydrate test-solution, previously diluted with 5 C.c. of water, the mixture will assume a yellow color which should not turn decidedly brown within twelve hours (limit of *aldehyde*). If 5 C.c. of recently prepared Spirit of Nitrous Ether be introduced into a nitrometer, and followed, first, by 10 C.c. of potassium iodide test-solution, and then by 10 C.c. of normal sulphuric acid, the volume of nitrogen dioxide generated at the ordinary indoor temperature (assumed to be at or near 25° C., or 77° F.) should not be less than 55 C.c., corresponding to about 4 per cent. of pure ethyl nitrite." *U. S.* When in undue proportion, alcohol and water may be detected in the British preparation, in a rough way, by agitating it with twice its volume of a saturated solution of calcium chloride. Specific gravity is no criterion of the quality of the preparation as obtained by any formula. The addition of water will raise its density; and the same effect will be produced by adding nitrous ether. A high density, in connection with deficient ethereal qualities, would of course indicate free acids, or an excess of water, or both. A specific gravity lower than the U. S. and Br. standard would show the presence of alcohol either stronger than it should be or in too large a proportion. The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering its extensive use and its valuable remedial properties. Water is injurious not merely as a diluent but also as the most efficient promoter of chemical changes. In commerce this valuable medicine is usually found variously diluted with twice, thrice, and even *four* times its weight of alcohol and water. In this way its ether strength is greatly reduced. Dr. Squibb examined six samples of sweet spirit of nitre, five of which were obtained from respectable wholesale druggists; of these one sample contained 3·16 per cent. of nitrous ether, four between one and two per cent., and one under one per cent.; while a standard preparation, made according to the U. S. Pharmacopœia, contained at least 4·3 per cent. The addition of glycerin to spirit of nitrous ether has been highly recommended as a preservative.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone or in conjunction with tartar emetic, for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving *nausea* and removing *flatulence*, and not unfrequently quiets restlessness and promotes sleep. It is especially selected in cases in which the tendency is asthenic. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill,

digitalis, potassium acetate, nitre, etc., for the purpose of promoting their action in dropsical complaints. Dr. Duncan, of Edinburgh, praised a combination of it with a small proportion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of febrile disease. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.) every two or three hours, mixed with a portion of water. When used as a diuretic, it should be given in larger doses.

The inhalation of sweet spirit of nitre produces acceleration of the pulse, with a peculiar leaden purple color of the lips, mouth, and finger-tips, followed by flushing of the face, extreme giddiness, nausea, muscular debility, and violent headache, excessively rapid irregular pulse, and dyspnœa. These symptoms undoubtedly depend in great part upon the presence of the ethyl nitrite, whose action is without doubt like that of other nitrites, being simply somewhat less prompt and fugacious than that of amyl nitrite, because the ethyl compound is less volatile, and therefore less rapidly absorbed and eliminated. The death of a child three years old is said to have been caused by between three and four ounces of the nitrite.

SPIRITUS AMMONIÆ. U. S. Spirit of Ammonia.

(SPĬR′Ĭ-TŬS ĄM-MŌ′NĬ-Æ.)

"An alcoholic solution of Ammonia [$NH_3 = 17·01$] containing 10 per cent., by weight, of the gas." *U. S.*

Liquor Ammonii Caustici Spirituosus, *P. G.;* Spiritus Ammoniaci Caustici Dzondii; Alcoolé d'Ammoniaque, Liqueur d'Ammoniaque vineuse, *Fr.;* Weingeistige Ammoniakflüssigkeit, *G.*

"Stronger Ammonia Water, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Alcohol, recently distilled, and, after distillation, kept in glass vessels, *a sufficient quantity*. Pour the Stronger Ammonia Water into a flask provided with a safety funnel, and connected, by means of a glass condenser, with a well-cooled receiver containing *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, the delivery-tube of the condenser reaching to near the bottom of the receiver. Heat the flask carefully, and very gradually, to a temperature not exceeding 60° C. (140° F.), and maintain it at that temperature for about ten minutes. Then disconnect the receiver, and, having ascertained the ammoniacal strength of the contents by means of normal sulphuric acid (rosolic acid test-solution being used as indicator), add enough Alcohol to make the product contain *ten per cent.*, by weight, of Ammonia. Keep the Spirit in glass-stoppered bottles, in a cool place." *U. S.*

Spirit of ammonia is now official in the U. S. Pharmacopœia only, the British Pharmacopœia not having adopted it. It is a solution of caustic ammonia in alcohol. As prepared by the U. S. process of 1850, the ammoniacal gas was received in the alcohol and condensed by it; and the proportions of the ingredients were so adjusted as to give a preparation containing between 10 and 11 per cent. of ammonia, and capable of saturating about 30 per cent. of official sulphuric acid. Accordingly it agreed in ammoniacal strength, as it was intended it should do, with the U. S. *Liquor Ammoniæ*. Its sp. gr. was 0·831, or thereabouts. But in the official process of 1870 the materials for the generation of ammonia were mixed with a large proportion of water, the vapor of which came over to some extent with the gas and was condensed along with it. The resulting spirit was, therefore, somewhat diluted with water, and to an indefinite extent, so that the preparation had no precise sp. gr.; and, though the whole amount obtained contained all the ammonia generated, no accurate criterion of its relative strength could be made. This fault has been remedied in the present official process by substituting stronger water of ammonia for the ammonium chloride, water, and lime, and not permitting the temperature to rise above 60° C. (140° F.). In addition to this, the amount of ammonia present is determined by volumetric assay, and it contains the same quantity of ammonia that is present in ammonia water,—*i.e.*, 10 per cent. Alcohol which has been kept in the cask for a long time will be discolored when the gaseous ammonia is passed into it.

Properties. The spirit of ammonia, formerly called *ammoniated alcohol*, is "a colorless liquid, having a strong odor of ammonia, and a specific gravity of about 0·810 at 15° C. (59° F.). When diluted with water, it should respond to the tests for identity and purity mentioned under Ammonia Water (see *Aqua Ammoniæ*). If 3·4 Gm. (or 4·2 C.c.) of Spirit of Ammonia be diluted with water, it should require, for complete neutralization, 20 C.c. of normal sulphuric acid (each C.c. corresponding to 0·5 per cent. of Ammonia), rosolic acid being used as indicator." *U. S.* When good, it does not effervesce with dilute hydrochloric acid; but if old, or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbonic acid more slowly than does Liquor Ammoniæ.

Medical Properties and Uses. Spirit of ammonia is stimulant and antispasmodic, and is given in *hysteria, flatulent colic,* and *nervous debility.* It is, however, little used internally, the aromatic spirit, which is pleasanter and has similar properties, being preferred. The dose is from ten to thirty drops (0·6–1·9 C.c.) in a wineglassful (60 C.c.) of water. Spirit of ammonia dissolves resins, gum-resins, camphor, and the volatile oils, and is a very convenient addition to spirituous liniments intended to produce a rubefacient effect. Not more than one part of the spirit should, as a rule, be added to six or eight parts, by measure, of the liniment. It enters into no official preparation.

SPIRITUS AMMONIÆ AROMATICUS. U. S., Br. Aromatic Spirit of Ammonia.

(SPĬR′Ĭ-TŬS ĄM-MŌ′NĬ-Æ ĂR-Ǫ-MĂT′Ĭ-CŬS.)

Spiritus Ammoniæ Compositus; Spirit of Sal Volatile; Alcoolat ammoniacal aromatique, *Fr.;* Aromatischer Ammoniakgeist, *G.*

"Ammonium Carbonate, in translucent pieces, *thirty-four grammes* [or 1 ounce av., 87 grains]; Ammonia Water, *ninety cubic centimeters* [or 3 fluidounces, 21 minims]; Oil of Lemon, *ten cubic centimeters* [or 162 minims]; Oil of Lavender Flowers, *one cubic centimeter* [or 16 minims]; Oil of Nutmeg, *one cubic centimeter* [or 16 minims]; Alcohol, *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims]; Distilled Water, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. To the Ammonia Water, contained in a flask, add *one hundred and forty cubic centimeters* [or 4 fluidounces, 352 minims] of Distilled Water, and afterwards the Ammonium Carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the Carbonate is dissolved. Introduce the Alcohol into a graduated bottle of suitable capacity, add the oils, then gradually add the solution of Ammonium Carbonate, and afterwards enough Distilled Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Set the liquid aside during twenty-four hours in a cool place, occasionally agitating, then filter it through paper, in a well-covered funnel. Keep the product in glass-stoppered bottles, in a cool place." *U. S.*

"Ammonium Carbonate, 4 *ounces* (Imperial) or 100 grammes; Strong Solution of Ammonia, 8 *fl. ounces* (Imp. meas.) or 200 cubic centimetres; Oil of Nutmeg, 4½ *fl. drachms* (Imp. meas.) or 14·1 cubic centimetres; Oil of Lemon, 6½ *fl. drachms* (Imp. meas.) or 20·3 cubic centimetres; Alcohol (90 per cent.), 6 *pints* (Imp. meas.) or 3000 cubic centimetres; Distilled Water, 3 *pints* (Imp. meas.) or 1500 cubic centimetres. Place the Oil of Lemon, Oil of Nutmeg, and Alcohol with the Distilled Water in a retort; distil *seven pints* (Imp. meas.) or three thousand five hundred cubic centimetres; then distil and separately collect an additional *nine fluid ounces* (Imp. meas.) or two hundred and twenty-five cubic centimetres. Place the latter, together with the Ammonium Carbonate and the Strong Solution of Ammonia, in a bottle holding rather more than *a pint* (Imp. meas.) or rather more than half a litre; securely cork the bottle and gently warm it in a water-bath to 140° F. (60° C.), shaking from time to time until all the salt has dissolved. Filter the resulting solution when cold through cotton wool, and gradually mix the filtrate with the portion first distilled." *Br.*

In both of these formulas ammonium carbonate and uncombined ammonia are used; but they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water; while the British contains so much of the ingredients as may rise in distillation and be condensed with the seven pints of spirit that result. The strength of the former is definite, that of the latter more or less indefinite, as a portion of the materials must be left behind. The advantage arising from distillation, however, the avoidance of discoloration, is one which is well worth considering, although the spirit will always grow darker with age. The present preparation differs from that formerly official in the substitution of oil of nutmeg for oil of pimenta, it having been shown that oil of pimenta increased the tendency of the spirit to darken. Commercial oil of nutmeg frequently has a terebinthinate odor. Much care is needed to select for this preparation volatile oils that are fresh and of good quality. The translucent official ammonium carbonate, which is a mixture of bicarbonate and carbamate, does not dissolve in alcohol: the bicarbonate precipitates, and the carbamate dissolves. The object of the addition of free ammonia in the official processes is to convert the insoluble bicarbonate into the carbamate. The effloresced ammonium carbonate of commerce having parted with some of its ammonia is a bicarbonate: hence when it is used, unless more than the official proportion of the ammonia water be added, some of the ammonia salt will remain as the precipitate of

the ammonium bicarbonate. The difficulty of precipitation which so many pharmacists complain of is thus explained. It is a useful precaution to permit the ammonium carbonate and ammonia water to remain in contact seven or eight hours before diluting with the other ingredients: this will secure the entire conversion of the bicarbonate, and obviate the precipitation above noted. It is officially described as "a nearly colorless liquid when freshly prepared, but gradually acquiring a somewhat darker tint. It has a pungent, ammoniacal odor and taste. Specific gravity, about 0·905 at 15° C. (59° F.)." *U. S.* "A transparent liquid having a pungent ammoniacal odor and flavor; nearly colorless when first prepared, but liable to darken slightly. Specific gravity 0·888 to 0·893.* 20 cubic centimetres require for neutralization 25·5 cubic centimetres of the *volumetric solution of sulphuric acid*, corresponding to about 2·4 per cent. of ammonia (NH_3), or 2·16 grammes in 100 cubic centimetres. 20 cubic centimetres, after the addition of 16 cubic centimetres of *solution of barium chloride*, should yield a precipitate which becomes more copious on heating to 160° F. (71° C.), and after filtering, the filtrate should yield a further precipitate when more of the reagent is added and the liquid is again heated." *Br.*

Medical Properties and Uses. Aromatic spirit of ammonia is fitted to fulfil the same indications as the simple spirit, but is much more used, on account of its grateful taste and smell. It is advantageously employed as a stimulant antacid in *sick headache*. The dose of the U. S. spirit is from thirty drops to a fluidrachm (1·9–3·75 C.c.), sufficiently diluted with water. Aromatic spirit of ammonia may be usefully added to aperient draughts, to render them less offensive to the stomach; but care must be taken not to mix it with incompatible substances. Most of the ammonia contained in it is probably in the state of the carbamate, which is converted into the carbonate upon the addition of water.

SPIRITUS AMMONIÆ FŒTIDUS. Br. Fetid Spirit of Ammonia.

(SPĬR'Ĭ-TŬS ĄM-MŌ'NĬ-Æ FŒT'Ĭ-DŬS.)

Alcoolat ammoniacal fétide, Essence antihystérique, *Fr.;* Ammoniakalischer Stinkasantgeist, *G.*

"Asafetida, 1½ *ounces* (Imperial) or 75 grammes; Strong Solution of Ammonia, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity.* Break the Asafetida into small pieces, and macerate it in a closed vessel in *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the Alcohol for twenty-four hours; distil until alcoholic vapors cease to be condensed; mix the distillate with the Strong Solution of Ammonia, and add sufficient Alcohol to make *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is an alcoholic solution of the volatile oil of asafetida mixed with strong water of ammonia, and is an energetic nervous stimulant and antacid, adapted to certain *hysterical conditions* associated with gastric weakness and acidity. It is one of the preparations formerly recognized by the British Colleges, and reinstated after having been dropped from the first British Pharmacopœia. "25 cubic centimetres should require for neutralization at least 42·5 cubic centimetres of the *volumetric solution of sulphuric acid*, corresponding to at least 2·88 grammes of ammonia (NH_3) in 100 cubic centimetres." *Br.* The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c), to be largely diluted when administered.

SPIRITUS AMYGDALÆ AMARÆ. U. S. Spirit of Bitter Almond.

[Essence of Bitter Almond.]

(SPĬR'Ĭ-TŬS Ą-MĬG'DĄ-LÆ Ą-MĀ'RÆ.)

"Oil of Bitter Almond, *ten cubic centimeters* [or 162 minims]; Alcohol, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Oil in the Alcohol, and add enough Distilled Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This is a new official spirit of the U. S. P. 1890: it is employed solely for flavoring purposes, and should always be used with care. The official oil of bitter almond now requires the presence of a trace of hydrocyanic acid, and hence the official spirit, containing 1 per cent. of oil, would show a slight trace. It would be safer to use for the spirit an oil free from hydrocyanic acid. A few drops only should be added to those substances which require a flavor.

* The specific gravity 0·888 to 0·893 is probably an error, 0·895 to 0·900 being nearer the truth.

SPIRITUS ANISI. U. S., Br. Spirit of Anise.

(SPĬR′Ị-TŬS Ạ-NĪ′SĪ.)

Essence of Anise; Alcoolat d'Anis, *Fr.;* Anisgeist, *G.*

"Oil of Anise, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Deodorized Alcohol, *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.* "Oil of Anise, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity.* To the Oil of Anise add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Anise. This Spirit of Anise contains half the proportion of Oil of Anise present in the Essence of Anise of the British Pharmacopœia of 1885," *Br.*, and is now of the same strength as the U. S. spirit. Dose, as a stomachic and carminative, from one to two fluidrachms (3·75–7·5 C.c.), properly diluted.

SPIRITUS ARMORACIÆ COMPOSITUS. Br. Compound Spirit of Horse-radish.

(SPĬR′Ị-TŬS ÄR-MỌ-RĀ′CỊ-Æ CỌM-PŌṢ′Ị-TŬS.)

Esprit de Raifort composé, Alcoolat antiscorbutique, *Fr.;* Meerrettiggeist, *G.*

"Horseradish Root, scraped, 5 *ounces* (Imperial) or 125 grammes; Dried Bitter-Orange Peel, well bruised, 5 *ounces* (Imp.) or 125 grammes; Nutmeg, bruised, 55 *grains* or 3·15 grammes; Alcohol (90 per cent.), 1¼ *pints* (Imp. meas.) or 625 cubic centimetres; Distilled Water, 1½ *pints* (Imp. meas.) or 750 cubic centimetres. Mix, and distil *two pints* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This may be used advantageously as an addition to diuretic remedies, in *dropsy* attended with debility, especially in the case of drunkards. Dose, from one to four fluidrachms (3·75–15 C.c.).

SPIRITUS AURANTII. U. S. Spirit of Orange.

(SPĬR′Ị-TŬS ÂU-RĂN′TỊ-Ī—âw-răn′shọ-ī.)

Alcoolat d'Huile d'Oranges, *Fr.;* Pomeranzengeist, *G.*

"Oil of Orange Peel, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Deodorized Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

This official was introduced at the U. S. 1880 revision. There was very little necessity for its introduction, because of the adoption of the tincture of sweet orange peel, which is identical in properties with the spirit, although not so strong. It serves a useful purpose, however, as a means of preserving the oil. (See *Oleum Aurantii.*) It is an excellent solution for flavoring purposes when the stimulant effect of the alcohol is desired.

SPIRITUS AURANTII COMPOSITUS. U. S. Compound Spirit of Orange.

(SPĬR′Ị-TŬS ÂU-RĂN′TỊ-Ī CỌM-PŌṢ′Ị-TŬS.)

"Oil of Orange Peel, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Oil of Lemon, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Oil of Coriander, *twenty cubic centimeters* [or 325 minims]; Oil of Anise, *five cubic centimeters* [or 81 minims]; Deodorized Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims. Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place." *U. S.*

This compound spirit has been introduced for the purpose of producing the orange flavor in making the official Elixir Aromaticum (page 497). It will be found by physicians to be a useful and fragrant addition to prescriptions.

SPIRITUS CAJUPUTI. Br. Spirit of Cajuput.

(SPĬR′Ị-TŬS CĂJ-Ụ-PŪ′TĪ.)

Alcoolé de Cajeput, *Fr.;* Cajeputgeist, *G.*

"Oil of Cajuput, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity.* To the Oil of Cajuput add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Cajuput." *Br.*

For an account of the medical properties and uses of oil of cajuput, of which this is simply an alcoholic solution, see *Oleum Cajuputi.* "This Spirit of Cajuput contains five times the

proportion of Oil of Cajuput present in the Spirit of Cajuput of the British Pharmacopœia of 1885." *Br.* Dose, from five to twenty minims (0·31–1·23 C.c.), properly diluted.

SPIRITUS CAMPHORÆ. U. S., Br. Spirit of Camphor.

(SPĬR'Ĭ-TŬS CĂM'PHŌ-RÆ.)

Tinctura Camphoræ, *U. S.* 1850; Tincture of Camphor; Alcohol Camphoratus; Spiritus Camphoratus, *P. G.;* Esprit de Camphre, Alcool camphré, *Fr.;* Kampferspiritus, *G.*

"Camphor, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Camphor in *eight hundred cubic centimeters* [or 27 fluidounces, 25 minims] of Alcohol, filter through paper, and pass enough Alcohol through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Camphor, 1 *ounce* (Imperial) or 50 grammes; Alcohol (90 per cent.), *a sufficient quantity*. To the Camphor add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Camphor." *Br.*

The present official spirit differs from that of 1880 in being made from alcohol *without dilution with water:* this change was recommended in the preceding edition of this commentary. The addition of water to the solution was by no means a practical improvement, in view of the extensive employment of the preparation in liniments containing chloroform, oils, etc., in which, of course, it was frequently immiscible without producing turbidity. This spirit is used as an anodyne embrocation in *rheumatic* and *gouty pains*, *chilblains*, and the inflammation resulting from *sprains* and *bruises*. M. Nélaton employed it, in the Clinical Hospital of Paris, in the dressing of open wounds, by compresses, lotion, or fomentation. (*Ann. de Thérap.*, 1865, p. 129.) It may also be employed internally, due regard being paid to the stimulant properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm (0·3–3·75 C.c.), first added to sugar, and then mixed with water.

SPIRITUS CHLOROFORMI. U. S., Br. Spirit of Chloroform.

(SPĬR'Ĭ-TŬS ȻHLŌ-RŌ-FÖR'MĪ.)

Chloric Ether, Spirit of Chloric Ether, *Br.;* Alcoolé de Chloroforme, *Fr.;* Chloroformspiritus, *G.*

"Chloroform, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Alcohol, *nine hundred and forty cubic centimeters* [or 31 fluidounces, 377 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Chloroform, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Chloroform add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Spirit of Chloroform." *Br.*

The chloroform strength of this preparation does not differ very greatly from that of the spirit of chloroform which was official in the United States Pharmacopœia of 1880; the latter contained 10 per cent. of chloroform by weight, whilst the spirit now official contains 6 per cent. by volume, the seeming difference being due to the specific gravity of the chloroform. Solution of chloroform in alcohol in variable proportions was at one time erroneously called *chloric ether*, and was used as a respiratory anæsthetic agent in the place of chloroform, under the impression that it would be safer, the stimulant properties of the alcohol obviating the sedative action of the chloroform. It is at present, however, little used in this way, practitioners who employ chloroform and yet wish to guard against its depressing effects preferring *ether* to alcohol as the corrigent. The spirit of chloroform is a convenient form for internal exhibition, as it is more readily incorporated in mixtures than chloroform itself. The dose is from ten to sixty minims (0·6–3·75 C.c.).* The official elixir of orange is an agreeable vehicle for its administration.

* *Alcoholic Solution of Chloroform.* A preparation for inhalation, composed of one-third pure chloroform and two-thirds nearly absolute alcohol, was recommended by Dr. Warren, under the name of *strong chloric ether*. Dr. Snow has since employed a similar mixture, using equal parts of chloroform and alcohol. The mixture, made in the proportion adopted by Dr. Snow, is commended by M. Robert as the best anæsthetic agent yet proposed. As the name chloric ether was originally applied by the late Dr. T. Thomson, of Glasgow, to the Dutch liquid, it would be well to abandon the same appellation to designate chloroform, or its mixture with alcohol. A correct name for the latter would be *alcoholic solution of chloroform*, or *tincture of chloroform*. Dr. Warren used his preparation in fifty cases with success, and considered it safer than chloroform, and more agreeable than ether, but there is no reason for supposing that it has especial value. The preparation sold in London and elsewhere under the name of "*chloric ether*" is a weak tincture of chloroform of variable quality, containing at most but 16 or 18 per cent. of chloroform, and sometimes not more than 5 or 6 per cent.

SPIRITUS CINNAMOMI. U. S., Br. Spirit of Cinnamon.

(SPĬR'Ị-TŬS CĬN-NĄ-MŌ'MĪ.)

Alcoolé de Cannelle, *Fr.*; Zimmtspiritus, *G.*

"Oil of Cinnamon, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Oil of Cinnamon, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Cinnamon add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Cinnamon." *Br.*

The spirit of cinnamon is an agreeable aromatic cordial. It contains five times the proportion of oil of cinnamon present in the spirit of cinnamon of the British Pharmacopœia of 1885. Dose, from five to twenty minims (0·3–1·2 C.c.) in water.

SPIRITUS FRUMENTI. U. S. Whiskey.

(SPĬR'Ị-TŬS FRŪ-MĔN'TĪ.)

"An alcoholic liquid obtained by the distillation of the mash of fermented grain (usually of mixtures of corn, wheat, and rye), and at least two years old." *U. S.*

Eau de Vie de Grains, *Fr.*; Kornbranntwein, *G.*

The term *whiskey* is said to have been first applied to the spirit obtained from barley in the Highlands of Scotland, and to signify water in the language of the people of that region. (*Rees's Cyclopædia.*) In the strict sense of the word, as at present understood, and as officially defined, it belongs to the distilled spirit from different grains, including Indian corn, wheat, rye, and barley. The whiskey of this country is generally made from corn or rye. The term, however, is sometimes extended to other forms of ardent spirit; and that resulting from the distillation of cider is frequently, although incorrectly, designated as *apple whiskey*.

In the preparation of whiskey, the infusion of rye or other grain is first made to undergo fermentation, by which the saccharine matter and indirectly the starch are converted into alcohol. In this state the liquid is called the *mash*. This is submitted to distillation, and the product is denominated *low wines*. By a second distillation it becomes purer and stronger, and now takes the name of raw corn spirit or whiskey. Sometimes, we are informed, it is submitted to a third distillation, in order still further to purify it. By time certain chemical changes take place by which the natural impurities contained in the liquor are destroyed, and the whiskey becomes mellow, losing the disagreeable odor and taste which it is apt to have when first distilled. It is generally believed that these changes involve the change of the aldehydic constituents of the raw spirit into acids which unite with the higher alcohols of the fusel oil to form esters which give the improved taste and mellowness to an aged whiskey.

There are volatile principles naturally existing in the grains, which accompany the liquor in all its changes and give their characteristic flavor to the resulting spirit. These can scarcely be considered as impurities. But there are others, produced during the process of fermentation, which serve seriously to contaminate the product. Among these is *fusel oil* or *grain oil* (amylic alcohol), which is offensive both to the smell and to the taste, and from which it is very desirable that the spirit should be freed as far as possible. This is determined in an approximately quantitative way by shaking out with carbon tetrachloride, oxidizing the solution so obtained with chromic acid mixture, and then titrating the valerianic and other acids obtained with decinormal barium hydroxide. Minute proportions of acetic and butyric acids are often present in whiskey, and valerianic acid has been detected. (*A. J. P.*, 1859, 573.) According to Dr. A. A. Hayes, of Boston, new spirits which have been prepared in copper stills are liable to be contaminated with that metal, which, however, is, he thinks, deposited in the process of ripening which they undergo by time. (*Am. Journ. Sci. and Arts*, July, 1861.)

Properties. Whiskey, when recently prepared, is nearly colorless; but when kept in casks it gradually acquires a brownish color, which deepens with time; and hence it may be found of various shades, from a slight yellowish brown tint to the dark brown of brandy. Its taste and smell, when mellow by age, though peculiar, are not disagreeable. According to the Pharmacopœia, whiskey is "an amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Its specific gravity should not be more than 0·930, nor less than 0·917, corresponding, approximately, to an alcoholic strength of 44 to 50 per cent. by weight, or 50 to 58 per cent. by volume. If 100 C.c. of Whiskey be very slowly evaporated in a tared capsule on a water-bath, the last portions volatilized should not have a harsh or dis-

agreeable odor (absence of more than traces of *fusel oil from grain*); and the residue, when dried at 100° C. (212° F.), should not weigh more than 0·25 Gm. This residue should have no sweet nor distinctly spicy taste (absence of *added sugar*, *glycerin*, or *aromatic substances*). It should almost completely dissolve in 10 C.c. of cold water, forming a solution which is colored not deeper than light green by a few drops of dilute ferric chloride test-solution made by mixing the latter with 10 volumes of water (absence of more than traces of *oak tannin* from casks). To render 100 C.c. of Whiskey distinctly alkaline to litmus should not require more than 1·2 C.c. of potassium hydrate volumetric solution (limit of *free acid*)." *U. S.*

Whiskey is an excellent alcoholic stimulant, which differs therapeutically from brandy in its having less tendency to cause constipation. Owing to its cheapness and its customary purity, it is usually preferable to brandy as a medicinal agent. It is also used as an antiseptic for wounds and ulcers.

SPIRITUS GAULTHERIÆ. U. S. Spirit of Gaultheria.

(SPĬR'Ĭ-TŬS GÂUL-THĒ'RĬ-Æ.)

"Oil of Gaultheria, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

This spirit, which was made official for the first time in the U. S. P. 1880, is simply a solution of the oil of gaultheria in alcohol in varying proportions: it has long been in use in many parts of our country, and authoritative recognition was needed. It is probably most largely used for imparting flavor to prescriptions. The dose is from ten to twenty minims (0·6°–1·25 C.c.).

SPIRITUS GLONOINI. U. S. (Br.) Spirit of Glonoin. [Spirit of Nitroglycerin.]

(SPĬR'Ĭ-TŬS GLŌ-NŌ-Ī'NĪ.)

Liquor Trinitrini, *Br.;* Solution of Trinitrin; Liquor Nitroglycerini; Solution of Nitroglycerine; Liquor Glonoini; Solution of Glonoin.

"An alcoholic solution of Glonoin [Glyceryl (or Propenyl) trinitrate, or Nitroglycerin; $C_3H_5(NO_3)_3 = 226·58$], containing 1 per cent., by weight, of the substance. Spirit of Glonoin should be kept and transported in well-stoppered tin cans, and should be stored in a cool place, remote from lights or fire. Great care should be exercised in handling, packing, transporting, or storing the Spirit, since a dangerous explosion may result if any considerable quantity of it be spilled and the alcohol be partly or wholly lost by evaporation." *U. S.*

"Trinitroglycerin of commerce, 17½ *grains* or 1 gramme; Alcohol (90 per cent.), *a sufficient quantity*. Dissolve the trinitroglycerin in sufficient of the Alcohol to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Trinitrin." *Br.*

This is a new official spirit. It has been introduced into the U. S. P. 1890 with the view of furnishing an eligible mode of administering nitroglycerin. The British Liquor Trinitrini is practically identical. Abundant precautions are included, which should on no account be neglected. The official description is as follows. "A clear, colorless liquid, possessing the odor and taste of alcohol. Caution should be exercised in tasting it, since even a small quantity of it is liable to produce a violent headache. The same effect is produced when it is freely applied to the skin. It is neutral to litmus paper. Specific gravity, 0·826 to 0·832 at 15° C. (59° F.). On diluting 10 C.c. of the Spirit with 15 C.c. of water,—both liquids, as well as the mixture, when measured, being brought to 15° C. (59° F.),—the liquid will exhibit at most a faint cloudiness, but the addition of a further portion of 5 C.c. of water should produce a white turbidity. If the specific gravity of the Spirit be higher than 0·840, or if 10 C.c. of it be rendered turbid by less than 10 C.c. of water, the Spirit should be rejected." *U. S.* "A clear and colorless liquid, neutral to *test-papers*. Specific gravity 0·840. A mixture of 10 cubic centimetres with an equal volume of *water*, cooled to 60° F. (15·5 C.), remains clear, but the further admixture of 1 cubic centimetre of *water* causes opacity (presence of a due amount of trinitroglycerin). On further diluting with *water* and setting the mixture aside, there is deposited a liquid of oily consistence, one drop of which, absorbed by paper and struck with a hammer on a hard surface, explodes. 110 minims contain 1 grain of trinitroglycerin; 100 cubic centimetres contain 1 gramme." *Br.* For a method of assaying this spirit by Dr. Rice, see *Amer. Drug.*, 1895, 6; also Nagelvoort's method, *A. J. P.*, 1894, 527. On account of the importance of nitroglycerin as a therapeutic agent, we append the following.

Nitroglycerin. Trinitrine. Glonoin. Glyceryl Trinitrate. ($C_3H_5(NO_3)_3$.) When glycerin is gradually added in small portions at a time to a mixture of one part of strong nitric acid and three to four parts of concentrated sulphuric acid, and at a temperature kept low by artificial refrigeration, it is converted into a bright yellow liquid, which has remarkable explosive properties and has received the name at the head of this article. Nitroglycerin was discovered in the year 1847 by Professor Sobrero, of Turin. It was afterwards made a subject of study by Dr. de Vrij, of the Netherlands, Dr. Gladstone, and Dr. Kopp, but did not attract general attention until 1867, when Alfred Nobel, a Swedish engineer, suggested its use for explosive purposes. It is a yellow liquid (said to be colorless or slightly yellowish when pure); of a sp. gr. from 1·525 to 1·6; inodorous; of a sweet, pungent, aromatic taste; very slightly soluble in water, but readily soluble in ether, alcohol, and methylated spirit; not freezing above —15·5° C. (4° F.) when quite pure, according to J. R. Wagner, but, as it occurs in commerce, solidifying by continued exposure to a temperature of 8° C. (46·4° F.), and assuming the form of long needles, which it is dangerous to handle, as they explode violently when gently broken. In the liquid state the mere contact of flame does not inflame or explode it; but concussion, or touching it with a red-hot iron, explodes it with great vehemence. Detonating mixtures, or exploding gunpowder, in its near vicinity, produce the same effect. By keeping it undergoes partial decomposition; and in confined vessels the pressure of the accumulated gases which result is sometimes so great as to cause its explosion upon the slightest concussion. Its explosive force greatly exceeds that of gunpowder. According to Nobel, one measure of the fluid yields on explosion 10,384 measures of gas, while one measure of gunpowder yields only 800 measures. It has, therefore, been much employed in blasting rocks, in mining, quarrying, road-making, etc.; and its economical advantages have kept it in extensive use, notwithstanding the danger. From these facts the inference is evident that it should not be kept in large quantities, nor conveyed to any considerable distance: the most fearful consequences have followed a neglect of these precautions. Practical operators recommend that it should be made extemporaneously where wanted as an explosive agent.

Nitroglycerin is formed by the introduction of the nitro-group (NO_2) in place of the three replaceable hydrogen atoms of the glycerin formula, according to the reaction $C_3H_5(OH)_3 + 3(NO_2,OH) = C_3H_5,(NO_3)_3 + 3(HOH)$. M. E. Kopp gives the following as his method of preparing nitroglycerin on the spot where it is needed. First, fuming nitric acid of the sp. gr. 1·51 to 1·53 is mixed with twice its weight of the strongest sulphuric acid. At the same time commercial glycerin, free from lead and lime, is evaporated in a pot to 30° or 31° Baumé, so that on cooling it shall have a syrupy consistence. Into 3300 grammes of the acid mixture, contained in a glass or porcelain capsule placed in a trough of cold water, 500 grammes of the prepared glycerin are slowly poured with constant stirring, great care being taken to prevent any sensible heating of the mixture. The whole is then to be left for five or ten minutes, after which the mixture is to be poured into five or six times its volume of cold water to which a rotatory motion has been given. The nitroglycerin precipitates rapidly in the form of a heavy liquid, which is separated by decantation, then washed with a little water which is decanted, and lastly is put into bottles. In this state it still contains a little acid and water; but these do not interfere with its use as an explosive agent. Latterly it has also been prepared by mixing 3½ parts of sulphuric acid of 1·83 sp. gr. with 1 part of potassium nitrate, and cooling this, when potassium sulphate will crystallize out. The acid drained off from this is peculiarly adapted for the formation of nitroglycerin, which then takes place rapidly and without so much dangerous development of heat.

Medical Properties and Uses. The action of nitroglycerin upon the human system is that of the nitrite. It differs in its influence from amyl nitrite solely in that its effects are not quite so prompt and are perceptible for a much longer time. The amount required to produce a sensible action is exceedingly small. Thus, Mr. J. M. Merrick experienced distinct effects from one-fortieth of a drop, and Mr. Field has recorded a temporary loss of consciousness and other alarming symptoms as produced by about one-forty-fifth of a drop. In the case of Mr. B. Schuchardt (*A. J. P.*, 1867), as much as ten drops are affirmed to have been swallowed, with the production of giddiness, violent, throbbing headache, weariness, and a semi-unconsciousness lasting several hours. According to Louis Kolipinski (*Med. News*, 1890), two drachms of the ordinary solution of nitroglycerin have been recovered from without very serious symptoms (amount taken doubtful). For a case in which death was legally decided to have been criminally produced by the poison, see *Journ. de Pharm.*, xxvi. 356. The inhalation of the vapors of nitroglycerin produces the same symptoms, so that care is recommended

in its manufacture. As nitroglycerin may be considered a glyceryl nitrate, its action as a nitrite appears at first remarkable. It has been shown, however, by Hay that during its alkaline decomposition it yields nascent nitrous acid, and it can scarcely be questioned that this acid is developed in the blood and acts upon the system.

Spirit of glonoin, or an equivalent solution of *nitroglycerin*, is very much used in *angina pectoris*, *asthma*, *convulsions*, and other diseases in which amyl nitrite is employed. (See *Amyl Nitris.*) As a *cardiac stimulant*, in collapse, poisoning by illuminating gas, and other conditions, it may be used either by the mouth or by subcutaneous injections. Dose, from one to two minims (0·06–0·12 C.c.).

SPIRITUS JUNIPERI. U. S., Br. Spirit of Juniper.

(SPĬR'Ị-TŬS JŪ-NĬP'Ẹ-RĪ.)

Alcoolat (Esprit) de Genièvre, *Fr.;* Wachholderspiritus, *G.*

"Oil of Juniper, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Oil of Juniper, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Juniper add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Spirit of Juniper. If the solution be not clear, agitate with a little *powdered talc*, and filter. This Spirit of Juniper contains two and a half times the proportion of Oil of Juniper present in the Spirit of Juniper of the British Pharmacopœia of 1885," *Br.*, and is now uniform in strength with the U. S. preparation.

This spirit is used chiefly as an addition to diuretic infusions. It is about 33 per cent. stronger than the spirit formerly official. The dose is from thirty to sixty minims (1·9–3·7 C.c.).

SPIRITUS JUNIPERI COMPOSITUS. U. S. Compound Spirit of Juniper.

(SPĬR'Ị-TŬS JŪ-NĬP'Ẹ-RĪ CŌM-PŎŞ'Ị-TŪS.)

"Oil of Juniper, *eight cubic centimeters* [or 130 minims]; Oil of Caraway, *one cubic centimeter* [or 16 minims]; Oil of Fennel, *one cubic centimeter* [or 16 minims]; Alcohol, *fourteen hundred cubic centimeters* [or 47 fluidounces, 163 minims]; Water, *a sufficient quantity*, To make *two thousand cubic centimeters* [or 67 fluidounces, 302 minims]. Dissolve the Oils in the Alcohol, and gradually add enough Water to make the product measure *two thousand cubic centimeters* [or 67 fluidounces, 302 minims]." *U. S.*

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of *dropsy*. It corresponds very closely to Holland gin. The dose is from two to four fluidrachms (7·5–15 C.c.).

SPIRITUS LAVANDULÆ. U. S., Br. Spirit of Lavender.

(SPĬR'Ị-TŬS LẠ-VĂN'DŬ-LÆ.)

Alcoolat (Esprit, Eau) de Lavande, *Fr.;* Lavandelspiritus, *G.*

"Oil of Lavender Flowers, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Deodorized Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Oil of Lavender, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Lavender add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Lavender. This Spirit of Lavender contains five times the proportion of Oil of Lavender present in the Spirit of Lavender of the British Pharmacopœia of 1885." *Br.*

Spirit of Lavender is used chiefly as a perfume, and as an ingredient in other preparations. The official spirit is about 33 per cent. stronger than the spirit of the U. S. P. 1870. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The Br. spirit is double the strength of the U. S. preparation. It is a grateful stimulant and carminative when administered in sweetened water. The dose may be from five to twenty minims (0·3–1·2 C.c.).

SPIRITUS LIMONIS. U. S. Spirit of Lemon. [Essence of Lemon.]

(SPĬR′Ị-TŬS LĮ-MŌ′NĬS.)

Alcoolat (Esprit) de Citrons, *Fr.;* Citronenessenz, *G.*

"Oil of Lemon, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Lemon Peel, freshly grated, *fifty grammes* [or 1 ounce av., 334 grains]; Deodorized Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Oil of Lemon in *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Deodorized Alcohol, add the Lemon Peel, and macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Deodorized Alcohol to make the Spirit measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This spirit is used chiefly for flavoring mixtures.

SPIRITUS MENTHÆ PIPERITÆ. U. S., Br. Spirit of Peppermint.

(SPĬR′Ị-TŬS MĔN′THÆ PĪ-PĘ-RĪ′TÆ.)

Essence of Peppermint; Spiritus Menthæ Piperitæ Anglicus, *P. G.;* Alcoolat (Essence) de Menthe poivrée, *Fr.;* Englische Pfefferminzessenz, *G.*

"Oil of Peppermint, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Peppermint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Oil of Peppermint in *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol, add the Peppermint, and macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Oil of Peppermint, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Peppermint add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Peppermint. This Spirit of Peppermint contains five times the proportion of Oil of Peppermint present in the Spirit of Peppermint, and half the proportion of Oil in the *Essence of Peppermint* of the British Pharmacopœia of 1885." *Br.* It is now uniform in strength with the U. S. spirit.

The distilled spirit has no advantage over a simple solution of the oil in alcohol, and this mode of preparing it has been adopted both in the U. S. and British Pharmacopœias. It has long been popularly used under the name of *essence of peppermint*. The spirit of peppermint affords a convenient method of administering a dose of the volatile oil, being of such a strength that when dropped on loaf-sugar it may be taken without inconvenience. The dose is from ten to twenty minims (0·6–1·25 C.c.), given as just mentioned, or mixed with sweetened water.

SPIRITUS MENTHÆ VIRIDIS. U. S. Spirit of Spearmint.

(SPĬR′Ị-TŬS MĔN′THÆ VĪR′Ị-DĬS.)

Tinctura Olei Menthæ Viridis, *U. S.* 1850; Essence of Spearmint; Grüne Minzessenz, *G.*

"Oil of Spearmint, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Spearmint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Oil of Spearmint in *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol, add the Spearmint, and macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U.S.*

The remarks made on the Spirit of Peppermint are equally applicable to this. Both are usually employed as carminatives. The Spirit of Spearmint may be given in the dose of thirty or forty drops (1·9–2·5 C.c.).

SPIRITUS MYRCIÆ. U. S. Spirit of Myrcia. [Bay-rum.]

(SPĬR′Ị-TŬS MŸR′CĮ-Æ.)

"Oil of Myrcia, *sixteen cubic centimeters* [or 260 minims]; Oil of Orange Peel, *one cubic centimeter* [or 16 minims]; Oil of Pimenta, *one cubic centimeter* [or 16 minims]; Alcohol, *twelve hundred and twenty cubic centimeters* [or 41 fluidounces, 122 minims]; Water, *a sufficient quantity*, To make *two thousand cubic centimeters* [or 67 fluidounces, 302 minims]. Mix the Oils

with the Alcohol, and gradually add Water until the solution measures *two thousand cubic centimeters* [or 67 fluidounces, 302 minims]. Set the mixture aside, in a well-stoppered bottle, for eight days, then filter it through paper in a well-covered funnel." *U. S.*

The distilled spirit has been abandoned and a formula for its preparation substituted. It will in many cases be found that, even when complying strictly with the directions of the formula, simple filtration will not produce a transparent spirit. The addition to the filter of a small quantity of magnesium carbonate rubbed up with a little of the spirit to a smooth paste will accomplish the object of clarification. For an English formula for bay-rum, see *P. J. Tr.*, 1896, 468.

This was a new official of the U. S. Pharmacopœia of 1860, and was defined as obtained by distilling rum with the leaves of *Myrcia acris*. It had been long in use as a most agreeable and refreshing perfume; and many persons, on account of the name, believed it to be prepared by distilling spirit from the leaves of the bay-tree (*Laurus nobilis*). It appears, however, that this was an error. (*A. J. P.*, July, 1861.) A leaf was presented to the late Prof. Maisch, brought from the West Indies, with the information that it was from the tree the leaves of which were used in preparing this spirit. He observed that it had precisely the characteristic odor and taste of bay-rum, and on comparing it with the leaves of a twig in the collection of the Academy of Natural Sciences of this city, brought by the late Dr. Griffiths from St. Croix, and labelled as the plant from which bay-rum was prepared, found that the two closely corresponded. From the characters of the leaf, Prof. Bridges suggested that it might belong to a plant of the family Myrtaceæ, most probably the *Myrcia acris* of De Candolle; and there is little room to doubt that *Myrcia acris* is the source of this very agreeable perfume.

Gen. Ch. *Calyx* five-parted, tube subglobose. *Petals* five. *Stamens* numerous, free. *Ovary* two- or three-celled. *Berry* one- or two-celled, one- to three-seeded. *Seed* subglobose, smooth; cotyledons foliaceous.

Myrcia acris. Swartz; De Cand. *Prodrom.* v. 243; Curtis's *Bot. Mag.*, 2d ser., vol. vi. pl. 3153.—*Myrtus acris.* Willd. *Sp. Plant.* p. 973. The *bayberry*, as it is sometimes called, is a tree of considerable size, with a straight stem and a thick pyramidal summit. The young branches are green and sharply four-angled. The leaves are opposite, from 3 to 5 inches long, very coriaceous, lanceolate, obtuse, wavy, somewhat revolute at the edges, with numerous parallel nerves, reticulated on the upper surface, and sprinkled with pellucid dots. They have a very fragrant odor, and are somewhat astringent. The flowers, which are arranged in pedunculate, axillary panicles, longer than the leaves, are small, and white with a reddish tinge. The aromatic berries are round, about as large as a pea, with seven or eight seeds.

The tree is a native of Jamaica and other West India islands. The spirit is probably prepared by distilling rum from the leaves; but we are without precise information on the subject, and it is not impossible that the leaves of other species may also be used. Indeed, an odor of pimenta which it appears to us may be sometimes detected suggests the idea that the leaves of this tree may be at least occasionally added to those of the bayberry. A *volatile oil* is also obtained from the leaves by distillation, and is now official. (See *Oleum Myrciæ.*)

Bay-rum is used chiefly as a refreshing perfume in cases of *nervous headache, faintness*, and other *nervous disorders*, either held to the nostrils, or applied on soft linen to the head and forehead. It is also grateful to the feeble and convalescent patient, by being sprinkled on the bedcovering or otherwise made to impregnate the air of the chamber.

SPIRITUS MYRISTICÆ. U. S., Br. Spirit of Nutmeg. [Essence of Nutmeg.]

(SPĬR'Ĭ-TŬS MĬ-RĬS'TĬ-ÇÆ.)

Alcoole (Esprit) de Muscade, *Fr.*; Muskatspiritus, *G.*

"Oil of Nutmeg, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Oil of Nutmeg, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Nutmeg add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Nutmeg. If the solution be not clear, agitate with a little *powdered talc*, and filter. This Spirit of Nutmeg contains five times the proportion of Oil of Nutmeg present in the Spirit of Nutmeg of the British Pharmacopœia of 1885." *Br.* It is double the strength of the U. S. spirit.

It is used chiefly for its flavor. Dose, from five to twenty minims (0·3–1·2 C.c.).

SPIRITUS PHOSPHORI. U. S. Spirit of Phosphorus. [Tincture of Phosphorus.]

(SPĬR′Ị-TŬS PHŎS′PHỌ-RĪ.)

"Phosphorus, *one and two-tenths grammes* [or 18½ grains]; Absolute Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Weigh the Phosphorus in a tared capsule containing water, then dry it carefully and quickly with blotting paper, and introduce it into a flask containing *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Absolute Alcohol. Connect the flask with an upright condenser supplied with cold water, and apply the heat of a water-bath, so that the Alcohol may be kept gently boiling, until the Phosphorus is dissolved. Then allow the liquid to become cold, and, if necessary, add to it enough Absolute Alcohol to make it measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Lastly, transfer the Spirit to small, dark amber-colored vials, which should be securely stoppered, and kept in a cool and dark place." *U. S.*

This new official is the basis of the Elixir of Phosphorus, and is rarely directly used in medicine. It should be freshly prepared, as it is not a stable preparation. Each fluidrachm contains about $\frac{1}{15}$ grain of phosphorus.

SPIRITUS RECTIFICATUS. Br. Alcohol (90 per cent.). [Rectified Spirit.]

(SPĬR′Ị-TŬS RĔC-TỊ-FỊ-CĀ′TŬS.)

"A liquid containing 90 parts by volume of ethyl hydroxide, C_2H_5OH, and 10 parts by volume of water; obtained by the distillation of fermented saccharine liquids." *Br.*

See *Alcohol* (p. 123).

SPIRITUS ROSMARINI. Br. Spirit of Rosemary.

(SPĬR′Ị-TŬS RŎŞ-MẠ-RĪ′NĪ.)

Spiritus Anthos; Alcoolat (Esprit) de Romarin, *Fr.;* Rosmarin Spiritus, *G.*

"Oil of Rosemary, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Rosemary add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Rosemary. This Spirit of Rosemary contains five times the proportion of Oil of Rosemary present in the Spirit of Rosemary of the British Pharmacopœia of 1885." *Br.*

The plant is no longer official.* It is a grateful perfume, and is used chiefly as an ingredient in lotions and liniments.

SPIRITUS VINI GALLICI. U. S., Br. Brandy.

(SPĬR′Ị-TŬS VĪ′NĪ GĂL′LỊ-CĪ.)

"An alcoholic liquid obtained by the distillation of the fermented, unmodified juice of fresh grapes, and at least four years old." *U. S.* "A spirituous liquid distilled from wine and matured by age, and containing not less than 36½ per cent. by weight or 43½ per cent. by volume of ethyl hydroxide." *Br.*

Spirit of French Wine; Eau de Vie, Cognac, *Fr.;* Branntwein, Franzbranntwein, *G.;* Acquavite, *It.;* Agua ardiente, *Sp.*

* *Rosmarinus. Rosemary.* (*Folia Rosmarini, s. Roris Marinis*, P. G.; *Folia Anthos; Feuilles de Romarin, Romarin*, Fr.; *Rosmarin, Rosmarinblätter*, G.; *Rosmarino*, It.; *Romero*, Sp.) "The leaves of Rosmarinus officinalis, Linné (nat. ord. Labiatæ)." *U. S.* 1880. *Gen. Ch. Corolla* unequal, with the upper lip two-parted. *Filaments* long, curved, simple, with a tooth. *Willd. Rosmarinus officinalis.* Willd. *Sp. Plant.* i. 126; *B. & T.* 207. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-colored branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, rigid, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish, woolly, and glandular beneath. The flowers are pale blue or white, and disposed in opposite groups at the axils of the leaves, towards the ends of the branches. The naked seeds are four in number, oblong. The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The leaves, which have already been described, have a strong balsamic odor, which is possessed, but in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on a volatile oil. (See *Oleum Rosmarini.*) The tops lose a portion of their sensible properties by drying, and become inodorous by age. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, etc., to which it imparts its agreeable odor and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavor to the honey of the districts in which the plant abounds. *U. S. D.*, 16th ed.

All liquids which have undergone the alcoholic fermentation yield an ardent spirit by distillation. (See *Alcohol*, p. 123.) When the alcoholic liquid is wine, the product of the distillation is brandy. This ardent spirit is subject to variation, according to the character of the wine from which it is distilled. The best brandy is obtained from French wines, and the kinds called Cognac and Armagnac are most esteemed. Cognac is probably the most profitable wine-producing region in the world, and has given its name to the most widely known brandy. Very large quantities of brandy are now made in California, but the taste is peculiar and easily distinguished from that of Cognac. Our Pharmacopœia formerly recognized French brandy exclusively; but since the revision of 1860 all spirits have been admitted under that name, when obtained from the juice of grapes and sufficiently strong and pure to meet the requirements below specified.

Properties. "A pale amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Its specific gravity should not be more than 0·941, nor less than 0·925, corresponding, approximately, to an alcoholic strength of 39 to 47 per cent. by weight, or 46 to 55 per cent. by volume. If 100 C.c. of Brandy be very slowly evaporated in a tared capsule on a water-bath, the last portions volatilized should have an agreeable odor free from harshness (absence of *fusel oil from grain* or *potato spirit*); and the residue, when dried at 100° C. (212° F.), should not weigh more than 1·5 Gm. This residue should have no sweet or distinctly spicy taste (absence of *added sugar*, *glycerin*, or *aromatic substances*). It should almost completely dissolve in 10 C.c. of cold water, forming a solution which is colored not deeper than light green by a few drops of dilute ferric chloride test-solution made by mixing the latter with 10 volumes of water (absence of more than traces of *oak tannin* from casks). To render 100 C.c. of Brandy distinctly alkaline to litmus should require not more than 1 C.c. of potassium hydrate volumetric solution (limit of *free acid*)." *U. S.* Besides alcohol, water, and volatile oil, it contains coloring matter, tannin, œnanthic ether described under *wine*, a little acetic ether, and a little aldehyde. Brandy is classed according to its color, as pale and high-colored. *Pale brandy* has a yellow color, derived from the cask in which it is kept. *High-colored* brandy has a deep-red color given to it, before importation, by burnt sugar (caramel), which is said to impart a more agreeable flavor. *Factitious brandy* is sometimes made from alcohol, deprived of fusel oil, and reduced to the proper proof by water, by adding to it acetic ether in the proportion of from half an ounce to an ounce to the gallon. *Oil of cognac*, which it is stated contains the aroma from wines, is made from compressed wine-lees by placing it in a still with five times its bulk of water, 2 per cent. of newly-slaked lime, 1 per cent. of potash, and 1 per cent. of common salt. The stirring apparatus is set in motion, steam applied, the heat allowed to rise gradually to 240° C. (464° F.), and the green oil separated; the average yield is very small (·003 per cent.); the oil is then rectified, and 2 grammes of it are added to 100 litres of 50 per cent. alcohol to impart the odor and taste which so-called "best brandy" should have. The proper color is then given by burnt sugar. The spurious liquid may be known by its leaving on evaporation a residue, containing sugar and no tannin, the absence of the latter being shown by the evaporated portion not striking a black color with ferric salts. The nature of the liquid may also be detected by the absence of aldehyde. For modes of detecting impurities in brandy and other ardent spirits, see Allen, *Com. Org. Anal.*, 3d ed., i. 143 *et. seq.*

Medical Properties. Brandy is esteemed cordial and stomachic, and is frequently given, in the form of toddy or milk-punch, in the sinking stages of *low fevers*. In the late London Pharmacopœia there was an official preparation of it, called *Mistura Spiritus Vini Gallici*, consisting of brandy, cinnamon water, the yolks of eggs, sugar, and oil of cinnamon. This, though a convenient form for the administration of brandy, was subsequently omitted. It has, however, been admitted into the new edition, and is now again official; but the oil has been left out. If prepared with the U. S. cinnamon water, it would certainly be sufficiently flavored without the addition of the oil.

STAPHISAGRIA. U. S. (Br.) Staphisagria. [Stavesacre.]

(STĂPH-Ĭ-SĂ'GRĬ-Ą.)

"The seed of Delphinium Staphisagria, Linné (nat. ord. Ranunculaceæ)." *U. S.* "The dried ripe seeds of Delphinium Staphisagria, Linn." *Br.*

Staphisagriæ Semina, *Br.;* Stavesacre Seeds.

Delphinium staphisagria, L., or stavesacre, is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five- or seven-lobed leaves, supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice

as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur, which encloses two spurs of the upper leaflets of the nectary. The seeds are in straight oblong capsules. The plant is a native of the south of Europe.

Properties. The seeds of stavesacre are officially described as "about 5 Mm. long, 3 or 4 Mm. broad, flattish-tetrahedral, one side convex, brown or brownish-gray, with reticulate ridges, containing a whitish, oily albumen and a straight embryo; nearly inodorous; taste bitter and acrid." *U. S.* Their virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, a nitrogenous substance, a mucilaginous saccharine matter, mineral salts, and a peculiar alkaloid called *delphinine** or *delphinia*, which exists in the seeds combined with an excess of malic acid. Marquis, in Dragendorff's laboratory in 1877, isolated the following four alkaloids: *delphinine*, $C_{22}H_{35}NO_6$, a crystallizable alkaloid, of bitter taste, weak alkaline reaction, soluble in alcohol, ether, and chloroform; *delphinoidine*, $C_{42}H_{68}N_2O_7$, amorphous, soluble in ether, alcohol, chloroform, reaction strongly alkaline, fusing point from 110°–120° C.; *delphisine*, $C_{27}H_{46}N_2O_4$, crystallizing in warty aggregations, soluble in ether, alcohol, and chloroform; *staphisagrine*, $C_{22}H_{33}NO_5$, only obtained amorphous, difficultly soluble in water and ether, easily soluble in alcohol and chloroform, of bitter taste, fusing point 90° C., of alkaline reaction in alcoholic solution. (*Pflanzenstoffe*, 2d ed., 1884, 617.) The total amount of alkaloids is about 1 per cent. According to Charalampi Kara-Stojanow (*Inaug. Diss.*, Dorpat, 1890), delphinine and delphisine have the same composition, $C_{31}H_{49}NO_7$, crystallize from their solutions in ether and petroleum benzin in identical forms, and have their melting points at 191° C. and 189° C., while delphinoidine has the formula $C_{25}H_{42}NO_4$.

Medical Properties and Uses. The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. A strong tincture has been employed as an embrocation in *rheumatism*. The ointment is used to destroy *lice* and the *itch-mite*. M. Bazin has used the extract internally in *eczema* in doses of a grain and a half (0·095 Gm.). (*Ann. de Thérap.*, 1851.) But its internal employment should be abandoned, and when used externally care should be exercised not to apply it to an abraded scalp, and only upon the unbroken epidermis. In some countries the seeds are used like Cocculus Indicus to intoxicate fish.†

STILLINGIA. U. S. Stillingia. [Queen's Root.]

(STĮL-LĬN'ĢĮ-Ą.)

"The root of Stillingia sylvatica, Linné (nat. ord. Euphorbiaceæ)." *U. S.*

Queen's Root, Silver Leaf, Queen's Delight; Stillingie, *Fr., G.*

From the fruit of *Stillingia sebifera* the Chinese procure a *vegetable tallow* in large quantities, which is said to be almost pure stearin and is much used in making candles. It exists between the shell of the seeds and the outer husk; the kernel, contained within the shell, yielding a liquid fixed oil. (*P. J. Tr.*, xii. 73.)

Stillingia sylvatica. L. *Mant.* (1767) 126; Willd. *Sp. Plant.* iv. 588; *B. & T.* 241. This

* If delphinine be rubbed up with an equal quantity of malic acid, and some drops of concentrated sulphuric acid added, there will be produced an orange-red color passing into rose, growing deeper after some hours, and finally changing from the edges to violet, and at last becoming cobalt blue. (Tattersall, *Chemical News*, 41.) It is stated that no other alkaloid and no other organic acid, except malic, affords this reaction.

† When given in poisonous doses to the lower animals, *delphinine* produces excessive salivation, followed by violent and repeated vomiting, great disturbance of respiration, failure of heart action, gradual enfeeblement of voluntary motion and of sensation, and a peculiar fibrillary spasm of the muscles of the abdomen, which are said to be characteristic of the poisoning. Elevation of temperature and glycosuria have both been noticed; death is said to occur always from failure of respiration, though the heart is greatly enfeebled and finally ceases in diastole. According to Gauthier, the period of depression of the heart and of sensibility is preceded by one of excitement. The pupils are dilated and the motor nerve finally paralyzed. (*Lond. Med. Rec.*, Oct. 1887.) Dr. Turnbull, in his work *On the Medical Properties of the Ranunculaceæ*, states that pure delphinine may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally, it acts like veratrine, but, according to Dr. Turnbull, produces more redness and burning and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle; and the friction should be continued till a pungent sensation is produced. Turnbull probably had an impure alkaloid; the doses just mentioned would not be safe with a pure delphinine.

Staphisagrine is said to act like delphinine, except that it does not depress the heart so much or produce fibrillary contractions. Although cases of human poisonings have occurred with staphisagria, we know of none in which the result has been fatal. The symptoms are similar to those produced in the lower animals. Kobert states that the alkaloids of staphisagria all resemble aconitine in their action, but that delphinoidine has some narcotic action.

is an indigenous perennial plant, commonly called *Queen's delight*, with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales. The plant grows in pine-barrens from Virginia to Florida, flowering in May and June. When wounded it emits a milky juice. For structural characteristics of stillingia, see *Drug. Circ.*, 1898, 5.

The root, which is the part used, is large, thick, and woody. It is officially described as "about 30 Cm. long, and nearly 5 Cm. thick, subcylindrical, slightly branched, compact, wrinkled, tough, grayish-brown, breaking with a fibrous fracture, showing a thick bark and porous wood, the inner bark and medullary rays having numerous yellowish-brown resin-cells; odor peculiar, unpleasant; taste bitter, acrid, and pungent." *U. S.* The odor is slight, peculiar, and somewhat oleaginous, but in the recent root is said to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. It imparts its virtues to water and alcohol. Dr. H. R. Frost thinks that the active principle is somewhat volatile, and states that the root loses much of its activity when long kept. Mr. W. Saunders has obtained from the root a volatile oil, which he found to possess the odor, taste, and peculiar acrimony of the root in a high degree. He procured six and a quarter ounces from five pounds of the dried root. It had a thick consistence, and required the addition of alcohol to render it fit for manipulation. Wm. Bichy (*A. J. P.*, 1885, p. 529) found an alkaloid which he named *stillingine*. It was obtained as an amorphous powder, volatilizable on heating, forming a sulphate in fine scale-like crystals.

Medical Properties and Uses. In large doses stillingia is emetic and cathartic, in smaller doses alterative, with some influence over the secretions. It has been long popularly used in South Carolina, but was first introduced to the notice of the profession by Dr. Thomas Young Simons (*Amer. Med. Recorder*, 1828, vol. xiii. p. 312) as a valuable alterative remedy in *syphilitic affections* and other affections ordinarily requiring the use of mercury. From the reports in its favor there seems no reason to doubt the efficacy of this medicine in *secondary syphilis*, *scrofula*, *cutaneous diseases*, *chronic hepatic affections*, and other complaints ordinarily benefited by alterative medicines. It is best given in the form of the official fluid extract: dose, half a fluidrachm increased to a fluidrachm. Stillingia is sometimes advantageously combined with sarsaparilla and other alteratives.*

STRAMONII FOLIA. U. S., Br. Stramonium Leaves.

(STRĄ-MŌ'NI-Ī FŌ'LI-Ą.)

"The leaves of Datura Stramonium, Linné (nat. ord. Solanaceæ)." *U. S.* "The dried leaves of Datura Stramonium, Linn." *Br.*

* *Syrupus Stillingiæ Compositus. Compound Syrup of Stillingia.* This syrup, notwithstanding its reputation as a model of polypharmaceutical skill, is largely used in the West and South. Dr. John King makes it as follows. Take of Queen's Root (Stillingia) 2 lbs. [avoirdupois]; Turkey-corn Root (Corydalis) 2 lbs. [av.]; Blue-flag Root (Iris versicolor) 1 lb. [av.]; Elder Flowers 1 lb. [av.]; Pipsissewa Leaves (Chimaphila) 1 lb. [av.]; Coriander ½ lb. [av.]; Prickly Ash Berries (Xanthoxylum) ½ lb. [av.]; Sugar, Refined, 24 lbs. [av.]; Water q. s., Alcohol, 76 per cent., q. s. Grind and mix the vegetable drugs together, place them in a convenient vessel, cover them with alcohol of 76 per cent., and macerate for three days. Then transfer the whole to a percolator and gradually pour alcohol on top until 4 pints of tincture have been obtained, which retain and set aside. Then continue the percolation with water, and of this second percolate reserve so much as contains a sensible amount of alcohol, and distil or evaporate the latter from it. Continue the percolation by water until the solution obtained is almost tasteless, and boil down this weaker infusion until, when added to the second solution, after the evaporation of its alcohol, it will make 24 pints. To these two solutions combined add the sugar, and dissolve it by heat, carefully removing any scum which arises as it begins to boil; and if it exceeds 28 pints, evaporate to that quantity with constant stirring. Then remove from the fire, and, when nearly cold, add the 4 pints of reserved alcoholic tincture and make 4 gallons of syrup, each pint of which will be equal to 4 fluidounces of the ingredients. The 24 pounds of sugar, when added to the 24 pints of solution, will always make more than 28 pints. (*N. R.*, May, 1880; see also *National Formulary*, PART II.)

Datura stramonium. L. *Sp. Pl.* (1753) 179; Willd. *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.* i. 17; *B. & T.* 192. The *thornapple* is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil sometimes six feet or more. The root is large, whitish, and furnished with numerous rootlets. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, dark green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled, having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal receptacle in the centre of each cell. It opens at the summit. There are two varieties of this species of Datura, one with a green stem and white flowers, the other with a dark reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter, however, is considered by some botanists as a distinct species, being the *D. tatula* of Linnæus. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia; and it is probable that its native country is to be found in some parts of the East. It is said to grow wild abundantly in Southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being retentive of life, are taken in the earth put on shipboard for ballast from one country to another, not unfrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung-heaps, the road-sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odor which it diffuses to some distance around. All parts of it are medicinal. The leaves and seeds only are now official, the root having been omitted in the former revision of the U. S. Pharmacopœia. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown* (*vulgo*, *Jimson*) *weed*, derived probably from its having been first observed in the neighborhood of that old settlement in Virginia. In India *Datura alba*, *D. ferox*, and *D. fastuosa* are used as poisons. Under the names of *Man t'o lo fa*, *Wan t'o lo hua*, and *Nau yeung fa*, the Chinese use as a medicine the flower-heads of the *D. alba*; according to Frank Browne, they contain 0·485 per cent. of hyoscine, free from other alkaloids. *El Bethene*, a Datura of the Sahara Desert, is capable of causing delirium, coma, and death; and it is probable that all the species of the genus are poisonous. Dr. A. R. L. Dohme (*Proc. A. P. A.*, 1894, 231) examined stramonium to determine the value in alkaloid of the various parts of the plant; he found that, in general, the fresh parts yielded more than the dried parts; the stems contained the most alkaloid, the seeds next, then the leaves, and the roots the least of all.

1. The *fresh leaves* when bruised emit a fetid narcotic odor, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medical virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odor in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0·58 per cent. of gum, 0·6 of extractive, 0·64 of green starch, 0·15 of albumen, 0·12 of resin, 0·23 of saline matters, 5·15 of lignin, and 91·25 of water. The leaves, if carefully dried, retain their bitter taste. They are officially described as "about 15 Cm. long, petiolate, dark green, smooth, ovate, pointed, unequal, especially at the base, coarsely and sinuately toothed; thin, brittle, and nearly inodorous; taste unpleasant, bitter and nauseous." *U. S.* The mesophyll contains cluster-crystals of calcium oxalate. For a paper on structural characteristics by Schlotterbeck and Van Zwaluwenburg, see *Proc. A. P. A.*, 1897, 202.

2. The *seeds* are small, kidney-shaped, pitted and wrinkled, flattened on the sides, of a dark-brown almost black color, inodorous unless bruised, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. The testa is dull brownish black, hard, and encloses a cylindrical, curved embryo, which is embedded in a whitish oily albumen. They are much more energetic in their action on the system than are the leaves. MM. Hirtz and Hopp inferred

from their experiments that one part of an extract prepared from them was equal in strength to five parts of an extract prepared in precisely the same manner from the leaves. (*Ann. de Thérap.*, 1862, p. 22.) Geiger and Hesse succeeded in isolating an alkaloid, to which the name *daturine* was given, and which Trommsdorff has repeatedly procured by their process. Von Planta (*A. J. P.*, 23, p. 38) found that daturine was identical with atropine, and this result has since been confirmed; but Ladenburg (*Berichte d. Chem. Ges.*, 13, p. 909) found that *Datura stramonium* contains two alkaloids, which he designated as *heavy* and *light daturine*. The more difficultly soluble heavy daturine fuses at 113·5° to 114° C. (237° to 237·2° F.), and must be considered as a mixture of *atropine* and *hyoscyamine*. It yields a gold salt fusing between 135° and 150° C. (275° and 302° F.), out of which, by crystallization repeated six times and by rejection each time of the mother-liquor, is obtained hyoscyamine gold-chloride fusing at 158° to 160° C. (316·4° to 320° F.). From the mother-liquors by evaporation is obtained nearly pure atropine gold-chloride fusing at 135° to 140° C. (275° to 284° F.). If the heavy daturine be repeatedly crystallized out of dilute alcohol, pure atropine can be isolated from it, fusing at 113·5° to 114·5° C. (237° to 238° F.), and yielding a lustreless gold salt fusing at 135° to 139° C. (275° to 282·2° F.). The light daturine is the alkaloid which Ladenburg and Meyer in a previous study had shown to be identical with hyoscyamine. Hence *Datura stramonium* contains the two alkaloids *atropine*, $C_{17}H_{23}NO_3$, and *hyoscyamine*, isomeric with the other, which *Atropa belladonna* contains. (*A. J. P.*, 1884, 440.) The mother-liquors from which hyoscyamine is obtained yield a difficultly crystallizable base, first called hyoscine, but now known as *scopolamine*. Its gold salt is more difficultly soluble than the gold salts of atropine and hyoscyamine, and affords a means of separation. The base, when purified, can be crystallized out of ether in colorless crystals, melting at 59° C. Its formula is $C_{17}H_{21}NO_4$, and it is decomposed by boiling with baryta water into *scopolin*, $C_8H_{13}NO_2$, and *atropic acid*, $C_9H_8O_2$. (Schmidt, *Pharm. Chemie*, 3te Auf., ii. 1339.) Gérard (*Journ. Pharm. Chim.*, 1892, 8) studied *daturic acid* obtained from stramonium seed.

Medical Properties and Uses. Stramonium, when taken either in small or in large doses, produces symptoms which are precisely similar to those caused by belladonna. Poisoning by it is indistinguishable from that produced by the deadly nightshade, and the closest studies have shown that the minute physiological actions of the two drugs are identical. The reader is therefore referred to the article upon belladonna.

Though long known as a poisonous and intoxicating herb, stramonium was first introduced into regular practice by Baron Störck, of Vienna, who found some advantage from its use in *mania* and *epilepsy*. Subsequent observation has not confirmed his estimate of the remedy; but the drug is still occasionally employed in mania. Other diseases in which it has been found beneficial are *neuralgia* and *rheumatic affections*, *dysmenorrhœa*, *syphilitic pains*, *cancerous sores*, and *spasmodic asthma*. In the last complaint it has acquired considerable reputation. It is employed only during the paroxysm, which it very often greatly alleviates or altogether subverts. The practice was introduced into Great Britain from the East Indies, where the natives are in the habit of smoking the dried root and lower part of the stem of *Datura ferox*, in the paroxysms of this distressing complaint. The same parts of *D. stramonium* were substituted, and found equally effectual. To prepare the roots for use, they are quickly dried, cut into pieces, and beaten so as to loosen the texture. The dried leaves answer the same purpose. They are smoked by means of a common tobacco-pipe. These and other narcotic leaves have also been used in the shape of cigars. The smoke produces a sense of heat in the lungs, followed by copious expectoration, and attended frequently with temporary vertigo or drowsiness, and sometimes with nausea. The remedy should not be used in plethoric cases, unless preceded by ample depletion, nor in any case where there is determination to the head. Dangerous and even fatal consequences have resulted from its incautious or improper use; and General Gent, who was instrumental in introducing the practice into England, is said to have finally fallen a victim to it.

Externally the medicine is used advantageously as an ointment or cataplasm in *irritable ulcers*, *inflamed tumors*, *swelling of the mammæ*, and *painful hemorrhoidals*.

Of the parts of the plant employed, the seeds are the most powerful. They may be given in the dose of a grain (0·065 Gm.) twice a day; an extract made by evaporating the decoction, in one-quarter or one-half the quantity. The dose of the powdered leaves is two or three grains (0·13–0·20 Gm.). The inspissated juice of the fresh leaves was formerly very commonly prescribed; but the alcoholic extract is now almost exclusively used, the dose being half a grain (0·03 Gm.). (See *Extractum Stramonii*.) A tincture and a fluid extract are also official,

to which the reader is referred. The dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained. Fifteen or twenty grains of the powdered leaves (1–1·3 Gm.), and a proportionate amount of the other preparations, have often been given daily without unpleasant effects.

STRONTIUM.

Sr; 87·3. (STRŎN′TI-ŬM—strŏn′shi-ŭm.)

Strontium belongs to the alkaline earth-group of metals, along with barium and calcium. It is a yellow metal, of the sp. gr. 2·5, somewhat harder than lead, and is sufficiently malleable to be hammered out into thin plates. It oxidizes quickly on exposure to air, and hence must be kept under naphtha, like the alkali metals. It has so far been prepared only in a small way by electrolysis from the chloride or the hydrate, the best procedure being that of Bunsen and Matthiessen.

For the preparation of pure salts, Barthe and Falières found that the following method permits the preparation of pure strontium salts with comparative ease, and has the advantages that no heat is necessary, and that the chemicals employed need not be pure.

Dissolve natural strontium carbonate (or the sulphide obtained by reduction of the sulphate) in just sufficient diluted hydrochloric acid (1 to 5); it will be an advantage if some of the carbonate or sulphide remains undissolved. The clear liquid, which contains calcium, barium, and strontium salts, besides small quantities of iron, alumina, and magnesia, is decanted from the deposit, and a small excess of ammonia added, which precipitates iron and alumina. To the filtrate is added an excess of sulphuric acid; the precipitate, consisting of strontium, barium, and calcium sulphates, is washed repeatedly by decantation with water containing from 1 to 2 per cent. of sulphuric acid, and finally with distilled water. This will remove all traces of magnesium and calcium sulphate. The precipitate is next treated in the cold with an excess of a solution of ammonium or potassium carbonate (1 to 10), stirring frequently for two days, and finally washing with distilled water by decantation. The mixture of carbonate and sulphate is treated with diluted hydrochloric acid, which dissolves strontium carbonate and traces of baryta. After allowing it to stand for twenty-four hours the clear liquid is decanted and filtered through a filter previously washed with diluted hydrochloric acid. To the perfectly clear filtrate are added 200 Gm. of hydrochloric acid per liter, and then from 2 to 3 Gm. of precipitated strontium sulphate, which may contain barium sulphate; stirring frequently for several hours. The strongly acid liquid dissolves a little strontium sulphate (about 0·25 per cent.), but in proportion as the strontium is dissolved the barium takes hold of the sulphuric acid, while an equivalent quantity of strontium chloride is formed. The strontium sulphate being in excess will insure the final elimination of all the barium. The filtrate is evaporated to dryness, the salt dissolved in three times its weight of distilled water, allowed to stand for twenty-four hours, filtered, evaporated to crystallization, and dried. The crystals showed in the spectroscope only the lines of strontium. (*Bull. Soc. Chim.*, 1892, 104.)

In 1890, Dr. J. V. Laborde demonstrated that the traditional belief in the toxicity of the salts of strontium is incorrect. He found that fifteen grains intravenously given to a medium-sized dog produced no effect whatever, and that large quantities of the strontium salts might be mixed with the food of the animal without disturbing the general nutrition, the strontium salts being less harmful than the corresponding salts of potassium. Indeed, he asserts that during the administration of the strontium the animals gained in health and weight, and, further, that the eliminated strontium in the fecal and urinary discharges had a distinct beneficial antiseptic influence. It is stated that Vulpian in 1885 announced the value of strontium salts, but certainly to Laborde belongs the honor of first establishing their usefulness.

STRONTII BROMIDUM. U. S. Strontium Bromide.

$SrBr_2 . 6H_2O$; 354·58. (STRŎN′TI-Ī BRŌ′MI-DŬM—strŏn′shi-ī.)

"Strontium Bromide should be kept in glass-stoppered vials." *U. S.*

This salt, made official in the U. S. P. 1890, may be made by burning strontium in bromine vapor, by dissolving strontium carbonate in hydrobromic acid, or by substituting hydrobromic acid for hydrochloric acid in the latter part of the process given for preparing strontium salts. (See above.) It is officially described as in "colorless, transparent, hexagonal crystals, odorless, and having a bitter, saline taste. Very deliquescent. Soluble in 1·05 parts of water at 15° C. (59° F.), and in 0·5 part of boiling water. It is readily soluble in alcohol, and is precipi-

tated from this solution upon the addition of an equal volume of ether, in which it is insoluble. When heated, the crystals at first melt, and then lose all their water (30·4 per cent.). The anhydrous salt fuses at 630° C. (1166° F.). To a non-luminous flame the salt communicates an intense, red color. The aqueous solution is neutral to litmus paper. With calcium sulphate test-solution the aqueous solution (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate test-solution, and other soluble sulphates. With potassium chromate test-solution it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate test-solution, or sodium carbonate test-solution, it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If a few drops of chloroform be added to 5 C.c. of the solution, then 1 C.c. of chlorine water, and the mixture shaken, the liberated bromine will dissolve in the chloroform, communicating to it a yellow or brownish-yellow color. The aqueous solution (1 in 20) should not be affected by hydrogen sulphide test-solution either before or after acidulation with a drop of hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.); nor by ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.). It should form no precipitate with potassium dichromate test-solution (absence of *barium*). If a few drops of starch test-solution be mixed with 5 C.c. of the aqueous solution, and then one or two drops of chlorine water added, no blue color should appear (absence of *iodine*). If 0·3 Gm. of Strontium Bromide, rendered anhydrous by thorough drying before being weighed, be dissolved in 10 C.c. of water, and 3 drops of potassium dichromate test-solution be added, it should require not more than 24·6 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to at least 98 per cent. of the pure salt)." *U. S.* For further tests, see *Proc. A. P. A.*, 1897, 608.

Medical Properties and Uses. Strontium bromide has been strongly commended as a substitute for potassium bromide in the treatment of *epilepsy* and allied conditions. It depends for its action on the nervous system upon the presence of bromine in it, and appears to act upon the nervous centres in much the same manner as does the corresponding salt of potassium. Its influence upon the general nutrition is much more favorable than is that of the potassium salt, and it is much less apt to produce the disagreeable effects of bromism. Moreover, it is less irritating to the gastro-intestinal mucous membranes, on which, indeed, it often seems to exert a beneficial influence; and it probably acts as a powerful intestinal antiseptic. For these reasons many cases of epilepsy tolerate it much better than they do other bromides. In the clinical experience of Dr. H. C. Wood, however, it has seemed to be in its anticonvulsive influence among the least powerful and certain of its class. Possibly this result has been due to Dr. Wood's not having employed it in sufficient dose, he never having administered more than two drachms a day, whilst the French observers affirm that it may be given with great advantage in the daily dose of three drachms. Strontium bromide is further stated by Professor Sée to have an extraordinary influence in the reduction of the excretion of sugar in *diabetes*, and to be a valuble remedy in the treatment of *gastric dilatation* and *catarrh*.

STRONTII IODIDUM. U. S. Strontium Iodide.

$SrI_2 . 6H_2O$; 448·12. (STRŎN'TI-Ī Ī-ŎD'I-DŬM.)

"Strontium Iodide should be kept in dark amber-colored, glass-stoppered vials." *U. S.*

This new official salt may be made by evaporating a solution of hydriodic acid saturated with strontium hydrate. It is officially described as in "colorless, transparent, hexagonal plates, odorless, and having a bitterish, saline taste. Deliquescent, and colored yellow by exposure to air and light. Soluble in 0·6 part of water at 15° C. (59° F.), and in 0·27 part of boiling water. Also soluble in alcohol, and slightly so in ether. When cautiously heated, the crystals melt and gradually lose their water (24·05 per cent.), becoming anhydrous. At a red heat, it is decomposed, losing iodine, and leaving a residue of strontium oxide. To a non-luminous flame it communicates an intense, red color. The aqueous solution is neutral, or very slightly acid, to litmus paper. With calcium sulphate test-solution it slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate test-solution, or other soluble sulphates. With potassium chromate test-solution it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate test-solution, or sodium carbonate test-solution, it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If a few drops of starch test-solution be added to 5 C.c. of the solution, and then 1 C.c. of chlorine water, a bluish-black color will appear. The aqueous solution (1 in 20) should not be affected

by hydrogen sulphide test-solution, either before or after acidulation with a drop of hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.); nor by ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.). No turbidity should be produced in the aqueous solution by potassium dichromate test-solution (absence of *barium*). If 0·3 Gm. of Strontium Iodide, rendered anhydrous by thorough drying before being weighed, be dissolved in 10 C.c. of water and 3 drops of potassium dichromate test-solution be added, it should require not more than 18 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to at least 98 per cent. of the pure salt)." *U. S.*

Medical Properties and Uses. This salt has been brought forward as a means of obtaining the alterative influence of an iodide without irritating the intestinal tract or depressing the general nutrition. It contains about 56·5 per cent. of iodine, and, although its actual value has scarcely as yet been made out, may be substituted for potassium iodide in various diseases.

STRONTII LACTAS. U. S. Strontium Lactate.

$Sr(C_3H_5O_3)_2 . 3H_2O$; 318·76. (STRŎN'TI-Ī LĂC'TĂS.)

This new official salt may be prepared by the process of Thumann, who takes a certain quantity of finely powdered strontium nitrate which is thoroughly washed out on a funnel, closed with absorbent cotton, with strong alcohol; after drying, 44·84 Gm. of the strontium nitrate are dissolved in 1 liter of water and 10 Gm. of dilute sulphuric acid added, when all the barium present will be precipitated, together with a small quantity of strontium. The filtrate is treated with an excess of pure sodium carbonate (about 60 Gm. dissolved in 1 liter of water); the precipitated strontium carbonate is washed on a filter to free it from soda and sodium nitrate. To the strontium carbonate, contained in a tared beaker, are added 36 Gm. of absolute lactic acid diluted with 200 C.c. of water, and the mixture heated until solution is effected; then sufficient water is added to make the solution weigh 551 Gm., which will then represent 10 per cent. of pure, anhydrous strontium lactate. If the salt be desired, the solution may be evaporated, and the residue granulated. This is officially described as "a white, granular powder, or crystalline nodules, odorless, and having a slightly bitter, saline taste. Permanent in the air. Soluble in about 4 parts of water at 15° C. (59° F.), and in less than 0·5 part of boiling water. The solution saturated at a boiling heat remains liquid for many hours, even after being cooled to 0° C. (32° F.). Soluble in alcohol. When heated to 110° C. (230° F.), the salt loses its water (16·9 per cent.). At a higher temperature it first fuses, then is decomposed, giving off inflammable vapors, and leaves a residue of strontium carbonate and carbon, which, on the addition of hydrochloric acid, effervesces and communicates an intense, red color to a non-luminous flame. The aqueous solution (1 in 20) is slightly acid to litmus paper. With calcium sulphate test-solution the solution slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids. The same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate test-solution, or other soluble sulphates. With potassium chromate test-solution it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate test solution, or sodium carbonate test-solution, it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to 5 C.c. of the solution (1 in 20) 1 C.c. of sulphuric acid be added, and then 1 C.c. of potassium permanganate decinormal volumetric solution, the red color will rapidly disappear, while the mixture will effervesce and give off the odor of aldehyde. If 1 Gm. of the salt be dissolved in 19 C.c. of water, it should form a perfectly clear, colorless solution, leaving no insoluble residue (absence of *carbonate*, *oxalate*, etc.). The aqueous solution should not be affected by hydrogen sulphide test-solution, either before or after acidulation with a drop of hydrochloric acid (absence of *arsenic*, *lead*, etc.); nor by ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.). No turbidity should be produced in the solution by potassium dichromate test-solution (absence of *barium*). If 0·5 C.c. of silver nitrate test-solution be added to 5 C.c. of the aqueous solution (1 in 20), not more than a slight opalescence should be perceptible (limit of *chloride*, etc.). If 0·5 Gm. of the salt be placed upon a watch-glass, and 1 C.c. of sulphuric acid be carefully poured upon it, no effervescence should occur (absence of *carbonate*, *oxalate*, etc.); nor should any penetrating odor be perceptible, even after gentle heating (absence of *butyrate*, *propionate*, etc.); nor should the acid assume, within ten minutes, a deeper color than a pale straw-yellow (limit of *readily carbonizable*, *organic impurities*). If 1·33 Gm. of the salt, rendered anhydrous, before being weighed, by carefully drying at 110° C. (230° F.), be ignited, until most of the carbon has disappeared, and then distributed in 10 C.c. of water, it should require, for complete neutralization, not less than 9·9 C.c. of normal sulphuric acid (corre-

sponding to at least 98·6 per cent. of the pure salt), methyl-orange being used as indicator. *U. S.*

Medical Properties and Uses. Strontium lactate was originally brought forward by Dr. J. V. Laborde, who found it to have a distinct diuretic action. His researches led to clinical studies of the drug by Professors Germain Sée, Paul, Dujardin-Beaumetz, and others. It is asserted that strontium lactate, in doses of twenty grains, is an extremely successful remedy in the treatment of *nephritis* and chronic *albuminuria*, the urine being increased, the albumin lessened or entirely removed, and the general nutrition improved. It is stated that the action of this lactate upon the excretion of albumin is especially marked in epithelial and parenchymatous nephritis, but is much less pronounced in interstitial nephritis, and is not present when albuminuria is due to pulmonary congestion; also that it is not necessarily accompanied by an increased flow of urine, and is the result of an influence upon the tissues of the kidneys. Upon the intestinal canal the lactate is asserted to exert a very favorable influence. Strontium lactate has also been tried with alleged good results in the treatment of *rheumatism* and *gout*, it being affirmed that it increases the nitrogenous elimination and causes disappearance of the urates. Dose, from ten to thirty grains (0·65–1·95 Gm.) three times a day in solution.

STROPHANTHUS. U.S. (Br.) Strophanthus.

(STRŌ-PHĂN'THŬS.)

"The seed of Strophanthus hispidus, De Candolle (nat. ord. Apocynaceæ), deprived of its long awn." *U. S.* "The dried ripe seeds of Strophanthus Kombé, Oliver, freed from the awns." *Br.*

Strophanthi Semina, *Br.;* Strophanthus Seeds.

According to Engler and Prantl, there are twenty-eight recognized species of the genus found in Africa and Asia, extending to China, the East Indies, and the Philippines. The commercial drug is often largely composed of the seeds of other than the recognized official species, and may contain the seeds from related genera, especially those of *Kickxia africana.** The seeds of all the species of strophanthus apparently possess, however, hairs that have a characteristic thickened base somewhat resembling those of nux vomica seeds. The seeds of various species of the genus Strophanthus are used for the preparation of arrow-poison in Africa, at Kombé in the Manganja country, in the Gaboon district, and in Guinea and Senegambia. In Gaboon this poison is called *inée*, *onaye*, or *onage*. The plant which yields the arrow-poison of Kombé was first supposed by Prof. Oliver, of Kew, to be a distinct species, *S. kombé;* and although Prof. Oliver himself reached the belief that the plant is only a variety of *S. hispidus*, D. C., the revisers of the Br. Ph. maintain the correctness of his original opinion.

S. hispidus is a woody climber inhabiting the forests between the coasts and the centre of the continent. It reaches to the tops of the highest trees, coiling on the ground, and hanging in festoons from tree to tree. The stem is several inches in diameter. The flowers are cream-colored, yellow at the base, purplish-spotted above. They are grouped in terminal cymes. The lobes of their gamopetalous corollas are prolonged into very narrow tail-like ends, nine or more inches in length. They last but a short time during the months of October and November. The fruit, a pair of follicles from 10 to 17 inches long, is ripe in June, and is gathered by the natives, who scrape off the husks (epicarp and mesocarp) before drying, and preserve the more leathery internal inner covering (endocarp) with the enclosed seeds: hence the pods as they appear in commerce are smoothish and of a tawny color. The seeds themselves are covered with long comose hairs, which, being deciduous, are apt to be lost before the escape of the seed from the pod. In preparing the arrow-poison, the natives are said to pound the seeds deprived of their hairs to a pulp, add the adhesive sap of another plant, and simply smear the mixture for six inches along the point of the arrow. Game wounded by such an arrow is said to be rarely able to move a hundred yards, and the flesh is eaten without bad effect.

Strophanthus occurs in commerce either in pods or as clean seeds. Mr. Helbing states (*P. J. Tr.*, March, 1887) that he has found the seeds to constitute about 37 per cent., the pod (endocarp) 37 per cent., and the hairs about 25 per cent., and says that the quality of the pods may be determined by examining the color of the pappus. If these are white and bright, the seeds and pods are in good condition.

* The seeds of *Kickxia africana* are without hairs, spindle-shaped, not flattened, twisted into an S-like shape, and with the base and the point of the seed alike in their forms. On cross-section the cotyledons are seen much folded, whilst those of the strophanthus lie parallel one upon the other. The transverse section of the kickxia seed, when treated with concentrated sulphuric acid, first turns brown, then red, while the seeds of both kinds of strophanthus take on a green color.

Commercial strophanthus seeds may be arranged, according to the researches of Hartwich (*Arch. d. Pharm.*, 1892, 401), in the following groups: (1) The official products yielded by *S. hispidus* or *S. Kombé*, which contain strophanthin and no crystals of calcium oxalate. (2) Those resembling the official seeds, but of different habitat,—viz., Mozambique and Sierra Leone. (3) Those which contain calcium oxalate crystals, but no strophanthin,—viz., Senegal, Lagos, Niger, German East Africa, Togoland, and Baol of Senegal. (4) A very hairy seed from the Upper Niger. The hairs vary in color from a silky white to brown; the embryo contains calcium oxalate crystals, but the seeds do not contain strophanthin. (5) Seeds which are said to be glabrous, but possess hairs in the region of the raphe. These include those from Lagos and Zambesi, and contain neither calcium oxalate crystals nor strophanthin.

T. F. Hanausek has published an account (*Ph. Post*, 1887, 302) of the anatomy of the seeds of strophanthus, and recommends the use of sulphuric acid and potassium hydrate in distinguishing the seeds containing strophanthin. S. E. Jelliffe states that there are in the American market two hairy seeds, the product respectively of *S. hispidus* (Kombé) and *S. asper*, and one smooth seed, *S. gratus* of the Gaboon. He also gives an elaborate microscopical study with figures of these seeds. (See *Drug. Circ.*, 1896, 101.)

Glabrous Seeds. The Asiatic species and also some of the rare African species of strophanthus possess glabrous seeds. These seeds, for the most part, cannot yet be referred with certainty to any definite species. According to Franchet, the smooth seeds of the Gaboon are furnished by *S. gratus* and *S. thollonì*. It is noteworthy that *ouabaïn* is extracted from glabrous seeds and that *strophanthin* is the product of hairy seeds.

S. glaber is the species the seeds of which are used for preparing the *Kombé poison*. The seeds were for a long time confounded with those of *S. hispidus*, from which they are readily distinguished. The seeds are about thirteen to sixteen Mm. long from three to four and a half Mm. wide, and from one to one and a half Mm. thick. They are lanceolate with a rounded or truncated base and a long attenuate apex. The ventral face is flat or concave, the dorsal being convex, and possesses sometimes a small keel near the shaft. The surface is glabrous, of a dull waxy appearance; the color varies from an ochre-yellow to a fawn or cinnamon; the odor is characteristic; the fracture is horny and the taste extremely bitter. The hairs of the awn are about seven Cm. in length, numerous, silky, white, and when viewed in a mass yellowish or grayish. The seed coat is relatively thin; the albumen is thick and cartilaginous; the embryo is not thick, the radicle is as long as in *S. hispidus* or *S. Kombé*. With concentrated sulphuric acid the color changes from yellow to rose and finally to violet.

Typical strophanthus seeds are from one and one-half to two and one-half Cm. long, and from four to five Mm. broad. They are more or less rounded off at the base, without, however, losing the distinctly pointed shape; towards the upper end they become suddenly very much narrower, and end in the stalk of the pappus. They are flattened at the sides, and have a much more prominent keel-shaped ridge on one side than on the other; the seed is twisted slightly in the form of a spiral from the base to the apex. The color of the seeds varies from a grayish green to a brown, they being more or less covered with numerous appressed silvery hairs of silky appearance. They are officially described as "about 15 Mm. long and 4 or 5 Mm. broad, oblong-lanceolate, flattened and obtusely edged, grayish green, covered with appressed, silky hairs, one side with a ridge extending into the attenuated, pointed end; kernel white and oily, consisting of a straight embryo, having two thin cotyledons, and surrounded by a thin layer of perisperm; nearly inodorous; taste very bitter. A decoction prepared with 1 part of the seed and 10 parts of water has a brownish color, and is not changed in appearance on the addition of iodine test-solution, ferric chloride test-solution, or potassium mercuric iodide test-solution." *U. S.*

The Qualitative Examination of Strophanthus Seeds. C. Hartwich (*Arch. d. Pharm.*, 1892) declares the usual course for the qualitative examination of strophanthus seeds—as the external appearance, the bitter taste, and the few chemical tests—insufficient, and recommends a microscopical test for strophanthin to supplement the usual tests. In the examination of a great variety of strophanthus seeds some were found to contain starch, which is contrary to the general opinion.

For the valuation of the seeds the presence of strophanthin should be ascertained in the following manner. A fine cross-section of the seed is placed on a glass slide and covered with a drop of concentrated sulphuric acid. The endosperm at least should assume an intense green color, which is easily seen with a hand-glass. Often the green is preceded momentarily by a blue color. The cotyledons are also colored green, but generally less intensely than the endo-

sperm. Gradually the color changes through blue into red, and after ¼–1 hour it disappears. In seeds which contain but little strophanthin the endosperm alone is colored green, while the embryo is colored yellow and then red, or only the epidermis and the adjacent cells are colored in addition. Among the seeds examined by the author which failed to give the strophanthin reaction were the varieties Senegal and Lagos, and a number of others.

Tests for Tincture and Extract of Strophanthus. For testing the tincture three drops are taken, and for the extract a piece a little larger than a pin-head. In either case mix the drug with a half-drop of ferric chloride solution and three drops of sulphuric acid. A brown precipitate is formed which is distinctly green after one hour, and should retain the color for fully three hours.

MM. Hardy and Gallois have obtained from strophanthus two crystalline principles. One, which is a glucoside, they call *strophanthin;* the second, an alkaloid, they name *inæine.* The first-named appears to be the active principle of the poison. (*Journ. de Pharm.*, 3e sér., xxv. p. 176.) T. R. Fraser describes more fully the glucoside strophanthin. (*P. J. Tr.*, 1886, July 23.) When heated with dilute sulphuric acid it yields glucose and *strophanthidin*, which is insoluble in water, is very soluble in alcohol, and has a strongly bitter taste. *Strophanthin* is a white crystalline powder, neutral in reaction, intensely bitter, freely soluble in water, less so in rectified spirit, and nearly insoluble in ether and chloroform. According to E. Merck, it fuses at 185° C. Dr. Fraser has since (*A. J. P.*, 1889, p. 532) further investigated strophanthin. He found it difficult to separate, but obtained it pure by a somewhat tedious process, depending upon the formation of a tannate and subsequent decomposition by lead oxide. It yielded upon analysis results corresponding to the formula $C_{20}H_{34}C_{10}$. Thoms (*Ber. d. Chem. Ges.*, 1898, 534) obtained pure strophanthin. Arnaud gives its formula as $C_{31}H_{48}O_{12}$; this was confirmed by Kohn and Kulisch. Strophanthidin has the formula $C_{26}H_{38}O_7 + 1\frac{1}{2}H_2O$. Strophanthidin, the product of decomposition of the glucoside, is described as having an intensely bitter taste and a neutral reaction, and as being very slightly soluble in water, moderately soluble in cold and freely in warm alcohol. It crystallizes with great readiness. No alkaloid was detected, but in the lead precipitate from an aqueous solution of the alcoholic extract a compound was found of strongly acid reaction and freely soluble in water, to which the name of *kombic acid* has been given. The experiments of Prof. Fraser have shown that the active principle of strophanthus is most abundant in the seeds, but that it is contained also in the follicles and the hairs. Pharmaceutical preparations of the drug should, therefore, be made from the separated seeds, whilst the pericarp and the hairs may be employed for the manufacture of strophanthin.

Medical Properties and Uses. The first experiments with the Kombé arrow-poison were those of Prof. Thomas R. Fraser. (*Journ. of Anat. and Phys.*, vii. 141.) One-twentieth of a grain of the extract of the seeds produced in the frog stiffness of the limbs, gradual loss of reflex sensibility, arrest of the heart in systole, and, after a time, complete loss of voluntary movement,—the respiration continuing for a length of time after the cessation of the heart's beat. The loss of voluntary movement and the cessation of respiration appear to be due to a direct action of the poison upon the muscles themselves. The first influence of the poison upon the muscular fibre is to increase its tonicity, and when the muscle dies it does not go into relaxation, but passes directly from life into post-mortem rigidity. The drug seemed to exert little or no influence upon the spinal cord or the nerve-trunks.

These experiments have been abundantly confirmed by subsequent observers, so that it is fairly established that the Kombé arrow-poison is essentially a muscle-poison, and that it acts upon the muscles of the heart as it acts upon other muscles, only more vigorously. In some cases, especially in mammals, death occurs through respiratory paralysis, and not through cardiac arrest,—the respiratory muscles in these cases feeling the influence of the poison more powerfully than the heart. The value of the drug in practical medicine depends chiefly upon its heart-action, moderate doses of it producing in both man and the lower animals pronounced rise of the blood-pressure. It is probable that the muscles in the arterioles feel the effect of the drug, and by their contraction help in the elevation of the arterial pressure, although this is not proved, and Professor Fraser believes to the contrary. In man, the effect of full therapeutic doses of the drug is to lower the pulse from ten to thirty beats, increasing at the same time its force and volume, usually without producing other symptoms, unless it be increased diuresis. The effect upon the pulse comes on much more quickly and is much less permanent than that of digitalis, lasting usually from four to eight hours. The diuretic action of the drug seems to depend not only on its effect upon the circulation, but also largely on a direct

influence upon the secreting structure. Only one case of doubtful cumulative action has as yet been reported (see H. C. Wood's *Therapeutics*, 8th ed.), and it is probable that the active principle is both rapidly absorbed and rapidly and completely eliminated. Strophanthus is of great value in practical medicine in the same class of cases in which digitalis is employed. (See *Tinctura Strophanthi.*) It seems to be superior to digitalis as a diuretic, and therefore is especially indicated in cardiac dropsy. Strophanthus is locally irritating, and in some cases even therapeutic doses produce violent gastric pain and vomiting. Local anæsthetic properties have been claimed for strophanthin by Professor Panas, by M. Gley, by Hare and De Schweinitz, and by other observers. The irritating effects of strophanthin are, however, too great for its practical use, and it has been especially shown by Hare and De Schweinitz that the drug when placed in the eye is exceedingly prone to produce violent inflammation and even ulceration of the cornea.

Strophanthin has been used in medicine, but great caution is necessary in its employment, on account of its extreme activity (Prof. Fraser found that a solution of 1 part of strophanthin in 6,000,000 would stop the frog's heart) and the present absolute uncertainty as to the proper dose, growing out of its varying impurity. Rothziegel and Koralzewski maintain, however, that the active principle is more prompt and certain in its influence, and less apt to disturb the stomach, than are the ordinary preparations of the drug. They give the dose as from $\frac{1}{800}$ to $\frac{1}{200}$ of a grain (0·0002–0·0003 Gm.), and have in some cases administered as much as $\frac{1}{16}$ of a grain (0·004 Gm.) during twenty-four hours. When the alkaloid is given hypodermically the effect on the pulse is said to be manifest in five minutes. *Strophanthin tannate* contains 58·14 per cent. of strophanthin, and is given in the dose of from one-hundredth of a grain to one-sixtieth of a grain (0·0005 to 0·001 Gm.).

As the amount of strophanthin varies in true strophanthus seeds from 0·45 to 1 per cent. (Rice), it is plain that such preparations as tincture and extract must very greatly vary in their activity, even when carefully made from the drug. If it were possible to practically assay these preparations, the Pharmacopœia should direct only assayed preparations; but at present there seems to be no practical method known. We give in a foot-note a method suggested by Charles Rice,* which is, however, probably too expensive for practical use. Further, there is no official solid preparation of strophanthus for use in pills, etc., and the drug itself has never been exhibited. In experiments made by H. C. Wood and W. S. Carter the extract of strophanthus prepared by evaporating the official tincture was found to be as uniform and effective in its action as the tincture itself. When great accuracy of treatment is desired the alkaloid strophanthin should be preferred, and we think it should be made official and appropriate tests for its purity be given by the Pharmacopœia.

Much uncertainty seems still to surround the question as to what is the proper dose of strophanthin. If the strophanthus contains 0·5 per cent. of strophanthin, five minims of the tincture will contain 0·000075 Gm. or $\frac{1}{1000}$ gr. of the glucoside. If the strophanthus contains 1 per cent. of strophanthin, then five minims of the tincture would represent 0.00015 Gm. or $\frac{1}{500}$ gr. The dose of strophanthin as put in the book far exceeds these amounts. Rothziegel and Koralzewski suggested many years ago as the proper doses from 0.0002 to 0.0003 Gm. ($\frac{1}{300}$ to $\frac{1}{200}$ gr.), and as tablets of this strength have been used hypodermically to a considerable extent by the profession without the production of irritation or other disagreeable effect, at present this may be considered to be the proper commencing dose of the active principle of strophanthus, which has the advantage over the cruder preparation of being more distinct and certain in its action. According to the studies of Reynold W. Wilcox, the fluid extract of strophanthus is much more prone to cause sickness of the stomach than are the other preparations.

STRYCHNINA. U. S., Br. Strychnine.

$C_{21}H_{22}N_2O_2$; 333·31. (STRĬGH-NĪ'NA.) $C_{21}H_{22}N_2O_2$; 334.

"An alkaloid obtained from Nux Vomica, and also obtainable from other plants of the natural order Loganiaceæ." *U. S.* "An alkaloid, $C_{21}H_{22}N_2O_2$, obtained from the dried ripe seeds of Strychnos Nux-vomica, Linn., and other species of Strychnos." *Br.*

The U. S. and Br. Pharmacopœias very properly omit processes for preparing this alkaloid,

* "Take a large quantity of strophanthus seed in powder (which must, of course, be uniform in strength throughout) and treat a definite fraction of it—say 250 Gm.—by the proper method to separate from it the strophanthin in a sufficiently pure state to be weighed. Upon the basis of this assay the remainder of the powder is to be used for making a tincture or extract of a known strength."

as it can be made profitably only by the manufacturing chemist on a large scale. (See *U. S. D.*, 17th ed., p. 1295.)

The bean of St. Ignatius yields strychnine more easily and more largely than nux vomica.*

If thought desirable, brucine may be in great measure separated from the strychnine of commerce, by dissolving the latter in very dilute nitric acid, filtering, and concentrating. Brucine nitrate crystallizes in short, thick, dense prisms grouped together; strychnine nitrate in radiated tufts of long, light, capillary needles. By gentle agitation with the liquid, the latter salt is suspended and may be poured off, leaving the former. The alkaloids may be obtained by dissolving the salts in water, and precipitating with ammonia.

Properties. As usually found in commerce, strychnine is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or rhombic prisms with pyramidal capping. It is officially described as in "colorless, transparent, octohedral or prismatic crystals, or a white, crystalline powder, odorless, and having an intensely bitter taste perceptible even in highly diluted (1 in 700000) solution. Permanent in the air. Soluble, at 15° C. (59° F.), in 6700 parts of water, and in 110 parts of alcohol; in 2500 parts of boiling water, and in 12 parts of boiling alcohol. Also soluble in 7 parts of chloroform, but almost insoluble in ether. When heated to 268° C. (514·4° F.), Strychnine melts. Upon ignition it is consumed, leaving no residue. Strychnine has an alkaline reaction upon litmus paper. If a minute quantity of Strychnine be dissolved in about 0·5 C.c. of concentrated sulphuric acid on a white porcelain surface, and a small crystal of potassium dichromate slowly drawn across the liquid with a glass rod, there will be produced at first, momentarily, a blue color, which quickly changes to purplish-blue, then gradually to violet, purplish-red, and cherry-red, and finally to orange or yellow. On dissolving 0·02 Gm. of Strychnine in 2 C.c. of nitric acid (specific gravity 1·300), in a small test-tube, the acid should not turn more than faintly yellow (limit of *brucine*)." *U. S.* "Trimetric prisms; colorless and inodorous; very sparingly soluble in *water*, but communicating to it an intensely bitter taste; soluble in 150 parts of cold but in less of boiling *alcohol* (90 per cent.), and in 6 parts of *chloroform;* slightly soluble in cold *absolute alcohol*, but readily in 40 parts of boiling *absolute alcohol*, and nearly insoluble in *ether*. *Sulphuric acid* forms with it a colorless solution, which on the addition of *potassium bichromate* acquires an intensely violet hue, speedily passing through red to yellow. When *sulphuric acid* containing one-two-thousandth part of *potassium permanganate* is brought into contact with a minute particle of Strychnine, a violet coloration results. Not colored by *nitric acid* (absence of brucine); leaves no ash when burned with free access of air (absence of mineral impurities)." *Br.* It melts like a resin, is decomposed at a comparatively low temperature, and entirely dissipated at a red heat. Dr. Guy obtained a crystalline sublimate, at a heat but a few degrees below that at which it begins to change color and undergo decomposition. Its melting point is given as 284° C. (543° F.), but, according to Flückiger, in small portions it melts as low as 225° C. and can with care be sublimed without decomposition. According to Dr. Waddington, when heated to decomposition it emits a most suffocating odor, resembling the smell of asphaltum. (*P. J. Tr.*, March, 1868, p. 413.) Fused with an excess of potassium hydrate, it yields, according to Goldschmied (*Ber. Chem. Ges.*, 15, p. 1977), *indol*, C_8H_7N, and when distilled with zinc dust it yields a *dimethyl pyridine*, C_7H_9N, and *carbazol*, $C_{12}H_9N$. The volatile oils dissolve it freely. Benzin dissolves 0·607 per cent. of it, and amylic alcohol 0·55 per cent. (Dragendorff, *Journ. de Pharm.*, 4e sér., iv. 473.) It has an alkaline reaction on test-paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in commerce, in consequence of the presence of brucine. M. Eugène Marchand proposes the following test by which a very minute proportion of strychnine may be detected. If a little of the alkaloid be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of color; but if the least quantity of lead peroxide be added to the mixture, a magnificent blue color will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (*Journ. de Pharm.*, 3e sér., iv. 200.) Professor Otto recommended as a test a minute quantity of solution of potassium dichromate, which, added to the solution of strychnine in concentrated sulphuric acid, produces a splendid violet color.

* M. J. F. Molyn proposes, previously to the extraction of strychnine, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the strychnine and brucine igasurates, producing with these bases very soluble lactates. For the particulars of this process see *A. J. P.* (xix. 99), and for other processes see U. S. D., 14th ed., p. 1456.

(*A. J. P.*, xix. 77.) A similar change of color is produced, according to Dr. E. W. Davy, by substituting a strong solution of potassium ferricyanide (red potassium prussiate) for that of potassium dichromate. (*Ibid.*, xxv. 414.) It appears that any substance capable of yielding nascent oxygen readily will serve to develop the characteristic violet color, when applied after the addition of sulphuric acid. Landerer has found that solid iodic acid or potassium iodate heated gently with strychnine gives rise to a beautiful violet color, gradually passing to red, which remains unchanged for many days. (*Ibid.*, March, 1861, p. 110.) According to Mr. Wm. Copney, the least efficacious agent is potassium chlorate, a much better is lead dioxide, a still better is manganese dioxide, and the best of all is potassium dichromate; and the general result of numerous experiments, recently made, is that the last-mentioned agent is the most effective. The sulphuric acid must be of not less sp. gr. than 1·84. The play of colors, according to Mr. Copney, is first blue, then purple, then crimson, which is followed by red and green, the latter sometimes giving place to yellow. It is stated that the 1-500,000th part of a grain may be detected. (See *A. J. P.*, xxviii. 459.) On the other hand, some chemists have found difficulties with the potassium dichromate test. Thus, Brieger (*Jahresb.*, 1850, p. 617) found that, unless the substance was first moistened with sulphuric acid and the dichromate added to it subsequently, the reaction of strychnine was interfered with by quinine, morphine, and especially by sugar. Sonnenschein (*Fresenius's Zeitschrift*, 9, p. 495) found that ceroso-ceric oxide was much more sensitive as a reagent to use with sulphuric acid for strychnine than potassium dichromate. This fact we can confirm from experience. It give a blue color lasting longer, which then becomes violet, and then a permanent cherry-red.* Vanadin-sulphuric acid (1 part

* To succeed in detecting the alkaloid when mixed in small proportion with organic matters, it is necessary first to disintegrate the organic matter, that the action of a solvent of the strychnine should not be impeded, and that the alkaloid should be completely separated from the foreign matter. The process of Messrs. Rogers and Girdwood, by which these objects are effected, is the following. Digest the substance supposed to contain the strychnine with a mixture of 1 part of hydrochloric acid and 10 of water, until it becomes apparently fluid. Filter, and evaporate the liquid to dryness by a water-bath. Treat the residue with alcohol as long as anything is dissolved, filter, and evaporate. Dissolve the residue in water, and filter. Add solution of ammonia in excess to the aqueous solution, and agitate in a bottle or long tube with half an ounce of chloroform. Upon repose the chloroform subsides, holding the alkaloid in solution. Draw it off by a pipette, and evaporate the chloroform over a water-bath. Moisten the dry residue with concentrated sulphuric acid, and expose the mixture for some hours to the temperature of a water-bath, by which means all the organic matter except the strychnine is decomposed. Treat the charred mass with water, filter, add excess of ammonia, and shake the mixture with a drachm of chloroform. Separate the chloroform as before; and, if the matter left after the evaporation of a small portion of it is charred by concentrated sulphuric acid, the whole of it must be treated in the same manner as the previous chloroform solution. The last chloroform solution obtained is then to be tested for strychnine. Take up a little of it in a capillary tube, and drop it on the smallest space of a warm porcelain capsule, so that each successive drop may be evaporated. When the capsule is quite cold, moisten the spot with concentrated sulphuric acid, and add a minute fragment of potassium dichromate. Should the characteristic color not be developed, it is said that, if there be the minutest quantity of strychnine present, the color will become visible on adding sulphuric acid rendered slightly yellow by chromic acid. In conducting the process, care must be taken not to stir the spot moistened by sulphuric acid with a rod before the addition of the dichromate, and not to expose the spot to a very strong light, which interferes with the chemical reactions. (*Lond. Med. Times and Gaz.*, June, 1857, p. 620.) The process of dialysis may be advantageously applied to the separation of strychnine from the organic matters containing it, when brought to the liquid state. (See *Dialysis*, PART II.) Diluted acetic acid may be used for extracting the alkaloid with other soluble substances from the contents of the stomach.

It is stated by Mr. C. W. Bingley that, if much tartar emetic be contained in a solution with a little strychnine, a pale greenish color is produced instead of the violet; and, in like manner, if antimony chloride be present, the sulphuric acid and potassium dichromate test fails altogether. (*Chem. Gaz.*, June 16, 1856, p. 229.) Mr. Richard Hagen, having been induced, by the assertion of Von Sicherer that this test fails when the strychnine is mixed with tartar emetic or other tartrates, or even tartaric acid, to investigate the subject, ascertained that this statement, as a rule, is erroneous; for the reaction takes place with strychnine or its hydrochlorate though mixed with 20 or 30 parts of antimony tartrate; yet when *strychnine nitrate* is used with 20 parts of the antimonial tartrate, the mass almost instantly acquires a green color with the reagents mentioned. But even with strychnine nitrate the test succeeds if lead peroxide is used instead of chromic acid as the oxidizing agent. (*Ibid.*, Oct. 15, 1857, p. 398.)

For a particular account of the results produced by the reaction of a large number of substances with strychnine, the reader is referred to a paper by T. G. Wormley, in the *Chemical News* for April 14 and 28, 1860 (pp. 218 and 242). Among other trials made by him was that of the action of this alkaloid on frogs, proposed as a test by the late Dr. Marshall Hall. The poison was injected into the stomachs of the animals through a pipette. A solution containing 1 per cent. of strychnine produced rigidity and violent tetanic spasms immediately, and death in 8 minutes. With 1 part of strychnine to 1000 of the menstruum, the spasmodic symptoms were induced in 3 or 4 minutes; with 1 in 10,000, in from 10 to 24 minutes; with 1 in 20,000, and 1 in 30,000, the symptoms were less unequivocal, though tetanic spasms were noticed in some of the animals.

Experiments by Mr. W. A. Guy on the effects of sulphuric and nitric acids on strychnine and many other alkaloids, published with tabulated results, show that in no one out of 66 proximate principles, chiefly alkaloids, was the same change of color produced as in strychnine by concentrated sulphuric acid, followed by a crystal of potassium dichromate. (See *A. J. P.*, Nov. 1861, p. 517.) In the same number of the same journal (p. 527) is a paper by Mr. T. E. Jenkins, giving the result of experiments with sulphuric acid and potassium dichromate on numerous alkaloids, all tending to prove the delicacy and certainty of this color-test of strychnine. Mr. A. Wynter Blyth distils the suspected alkaloid with a solution of potassium permanganate to dryness, condensing the vapor in a cold

of ammonium vanadate dissolved in 200 parts of pure sulphuric acid of 1·84 sp. gr.) is colored by strychnine at first violet-blue, passing into violet, and finally cinnabar-red. On dilution with water this color remains rose-red. According to Dragendorff, the color persists when as little as 0·001 milligramme of strychnine is used.

Mr. Wm. T. Wenzell states that, when very minute quantities of the alkaloid are being dealt with, much the best plan is to prepare a reagent by dissolving in 2000 grains of sulphuric acid one grain of potassium permanganate. The alkaloid, during the evaporation of its acidulated solution on the porcelain, collects in the margins of the film, and the smallest possible dot of the reagent is to be placed so that its margin comes in contact with that of the film. In this way, Mr. Wenzell affirms, he was able to detect 1-900,000th part of strychnine. (*A. J. P.*, xlii. 385.) Some doubt was thrown upon the value of this test by experiments which seemed to prove that the presence of morphine in excess, especially in connection with organic matter, so far modified or disguised the action of the test upon strychnine as to prevent the appearance of the characteristic color; but subsequent and carefully conducted experiments by the late Dr. Robert P. Thomas satisfactorily determined that the conclusions in relation to the effects of morphine were erroneous, and that whether alone or associated with organic matters, in small or in large quantity, it does not prevent the operation of this color-test if carefully applied. (*Am. Journ. of Med. Sci.*, Oct. 1861, and 1862, 1340; also *Journ. Amer. Chem. Soc.*, 1894, No. 12.) Strychnine consists of carbon, hydrogen, nitrogen, and oxygen, and has the formula $C_{21}H_{22}N_2O_2$. The salts of strychnine are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic but not by gallic acid, and is not affected by ferric salts. They are precipitated by the solution of iodine in potassium iodide, and the precipitate, though soluble in alcohol, is insoluble in the diluted acetic and hydrochloric acid of the U. S. Pharmacopœia. (Fairthorne, *A. J. P.*, xxvii. 212.)*

Strychnine is apt to contain impurities, of which the chief, besides brucine, are coloring matter and lime or magnesia. The two latter impurities are left behind when the adulterated alkaloid is incinerated in the open air. Pure strychnine leaves no ashes under these circumstances. Brucine is detected by the red color which it yields with nitric acid. Neither this nor sulphuric acid colors strychnine,—a test which serves to distinguish it from several other alkaloids.

Medical Properties and Uses. The effects of strychnine upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. In whatever way strychnine is introduced into the system, it acts, if in sufficient quantity, as a violent poison. The evidences of its slightest action are muscular twitchings and stiffness. After poisonous doses the symptoms usually come on not only speedily but very suddenly. They are convulsions, both tonic and clonic, affecting all the voluntary muscles, plainly reflex in character, and interrupted by periods of usually complete relaxation. Consciousness is undisturbed. The body is during the convulsion rigid, with the face drawn into the *risus sardonicus*, the limbs stiffly extended, and the whole person bowed backward in marked opisthotonos. The convulsions are accompanied with pain, and may be so severe as to cause death by locking the chest in a general respiratory spasm. This death during a convulsion may occur very early, and is accompanied by evident signs of asphyxia; if in any convulsion consciousness be affected, it is by approaching asphyxia, and is an evidence of imminent peril. In many instances the patient survives some hours and finally dies of exhaustion. The chief physiological action of strychnine is stimulation of the motor and

flask, and applying Nessler's test for ammonia to the liquid thus obtained. He finds that all the poisonous alkaloids differ, but are individually constant in the amount of ammonia yielded, and that the test is always competent to decide to which class the alkaloid belongs, and often what alkaloid it is. Strychnine yields half its nitrogen, or 5·09 per cent. of ammonia. For further particulars consult *Med. Times and Gaz.*, 1875, i. 387.

* When an aqueous solution of strychnine sulphate and potassium nitrite is boiled, an effervescence takes place, owing to the escape of nitrogen, and the solution becomes yellow. If ammonia is now added, a precipitate takes place, which has been found to consist of two alkaloids, resulting from the oxidation of the strychnine in different degrees. One of these the discoverer, P. Schutzenberger, proposes to name *oxystrychnine*, and the other *dioxystrychnine*. (See *A. J. P.*, March, 1859, p. 133.)

Methyl-strychnine. Methyl-brucine. These alkaloids are formed by replacing one of the atoms of hydrogen in strychnine by methyl (CH_3), which is effected by acting on the alkaloids by methyl iodide. A singular and, if verified, very important statement in relation to these modifications of strychnine and brucine, made by Stahlschmidt (*Ann. der Phys. und Chem.*), is that they are not poisonous. He gave to a rabbit five grains of methyl-strychnine without any bad symptoms, though the same animal was afterwards killed in five minutes by one-twentieth of a grain of strychnine placed upon its tongue. The important practical inference is that methyl iodide ought to be an antidote to strychnine. (See *A. J. P.*, May, 1860, p. 220.)

vaso-motor centres of the cord: the peripheral nerves are affected only by very large toxic doses, which exert both a direct and an indirect sedative influence upon them. The diagnosis of strychnine poisoning from tetanus, hysteria, and other convulsive diseases is to be determined by the jaw being affected after the limbs and trunk, the relaxation between the convulsions, the universality of the latter, the retention of consciousness, the rapidity of the attack, and the history of the case.

The best chemical antidote to strychnine is the potassium permanganate, which should be freely administered from time to time until a result is reached. Washing out the stomach with a solution of the permanganate is excellent, provided it is done early and the patient anæsthetized before any attempt is made. We have seen fatal spasm brought on before the stomach-tube reached the œsophagus. The general treatment of strychnine poisoning consists in the maintenance of absolute quiet, and the use of such spinal sedatives as chloroform, amyl nitrite, opium, chloral, and potassium bromide; tobacco, aconite, and various similar sedative substances have been used, but no drug which acts powerfully as a cardiac depressant should be employed. Chloroform and amyl nitrite act very promptly, but their impression is fugacious, and their use should be restricted to the arresting of convulsions so severe as to threaten life. Opium may be given in moderate doses, and very large doses of cannabis Indica have been employed in some cases with excellent result, but, as it exists in our markets, this drug is too uncertain for any reliance to be placed upon it. Potassium bromide and chloral are exceedingly valuable remedies. In any case of severe strychnine poisoning it would be advisable to begin the general medicinal treatment with the administration of half an ounce (15·5 Gm.) of potassium bromide. After this chloral may be given in from twenty- to thirty-grain (1·3–1·95 Gm.) doses, at intervals of greater or less length, according to the severity of the symptoms, inhalations of chloroform, ether, and amyl nitrite being practised *pro re nata*, and the bromide also being repeated in much smaller dose if it seems advisable.

In an investigation of the members of the pyridine series of bases by C. Greville Williams and W. H. Waters (*Proc. Roy. Soc.*, xxxii. p. 162, 1881), they found that β lutidine (dimethyl pyridine, C_7H_9N) was antagonistic to strychnine and an apparent antidote. When injected into frogs already under the influence of strychnine, it arrested the convulsions; or if given first and then followed by a fatal dose of strychnine, it prevented the appearance of the tetanus. (Blyth, *Poisons, their Effects and Detection*, 1884, p. 319.)

Ether acts too slowly to be comparable in its effects to chloroform in this toxæmia, but it must not be forgotten that chloroform is alleged to have produced sudden cardiac death in strychnine poisoning, and in the latter stages, when exhaustion has set in, ether certainly is the safer remedy. Under the latter circumstances alcohol should be freely administered, as tending not only to quiet spasm, but also to sustain the heart's action. On account of its stimulant effect upon the gastric mucous membrane, and of its tendency to excite the vaso-motor and motor centres of the spinal cord and thereby increase the activity of the circulation and the general systemic tone, strychnine is a very valuable tonic, which may be given along with iron and simple bitters in *anæmia*, and especially in cases of general relaxation. Its striking convulsive influence early led to its use in palsies, and it is habitually so employed to-day. As, however, the loss of muscular power in these cases is very rarely due in chief part, if at all, to depression of the spinal centres, it is not common to see any very marked result from the use of the drug. In *infantile palsies* and other affections in which the nutrition of the muscles is largely at fault, the injection of strychnine into the affected muscles is sometimes productive of great good.

As a respiratory stimulant strychnine is very valuable in *subacute* and *chronic bronchitis*, especially in old and feeble subjects, in advanced *adynamic pneumonia*, in *chloral*, *opium*, and other *narcotic poisoning*, and in the accidents of *anæsthesia*, when death is threatened from respiratory failure. In these cases it must be given in large doses, and, when the symptoms are urgent, hypodermically.

Strychnine, owing to its tendency to increase the activity of non-striated as well as of striated muscular fibres, is a valuable addition to laxative medicines where there is reason to suspect relaxation of the muscular coat of the bowel. By the oculists strychnine is much used in *atrophy of the optic nerve*. The dose of strychnine varies very greatly according to the effect desired. As a simple tonic from $\frac{1}{30}$ to $\frac{1}{40}$ of a grain may be given three times a day. As a stimulant in low diseases, in certain affections of the spinal cord, in chronic heart disease, and in the adynamic nervous conditions of chronic alcoholism, etc., much larger amounts may be given with great advantage. Very large doses should be given hypodermically from four to

six hours apart, and be ascended to rather than commenced with. In this way an amount of even three-quarters of a grain of strychnine a day may be reached.*

STRYCHNINÆ HYDROCHLORIDUM. Br. Strychnine Hydrochloride.

[Hydrochlorate of Strychnine, Brit. Pharm. 1885.]

(STRĬ℔H-NĪ′NÆ HĬ-DRŌ-℔HLŌ′RĮ-DŬM.)

$C_{21}H_{22}N_2O_2HCl.2H_2O$; 405·63.

"The hydrochloride of an alkaloid obtained from Nux Vomica and from other species of Strychnos." *Br.*

This salt of strychnine was made official for the first time in the Br. Ph. 1898; it is used in making *Liquor Strychninæ Hydrochloridi.* (See p. 826.) It is described as in "Small colorless trimetric prisms which readily effloresce in the air; soluble in 35 parts of *water* or in 60 parts of *alcohol* (90 per cent.), forming a solution which is neutral to *litmus* and intensely bitter to the taste. The salt should afford the reactions characteristic of hydrochlorides, and should respond to the qualitative tests mentioned under 'Strychnina,' but should not yield any characteristic reaction for sulphates. Dried at a temperature of 212° F. (100° C.) it should lose from 7·3 to 8·8 per cent. of moisture." *Br.*

In its physiological and therapeutic action and in its dose strychnine hydrochlorate is equivalent to strychnine sulphate. (See next article).

STRYCHNINÆ SULPHAS. U.S. Strychnine Sulphate.

(STRĬ℔H-NĪ′NÆ SŬL′PHĂS.)

$(C_{21}H_{22}N_2O_2)_2H_2SO_4.5H_2O$; 854·24. $(C_{21}H_{22}N_2O_2)_2H_2SO_4.5H_2O$; 856.

"Strychnine Sulphate should be kept in well-stopped vials." *U. S.*

Strychniæ Sulphas, *Pharm.* 1870; Strychninum Sulphuricum; Sulfate de Strychnine, *Fr.;* Schwefelsaures Strychnin, *G.*

A process for this salt is no longer official. That of the U. S. P. 1870 will be found in the foot-note.† Two forms of strychnine sulphate are known, the acid sulphate, or commercial sulphate, and the official or neutral sulphate. Commercial strychnine sulphate, $C_{21}H_{22}N_2O_2.H_2SO_4 + 2H_2O$, crystallizes in needles. The water is expelled at 150° C. (302° F.). To prepare the neutral sulphate $(C_{21}H_{22}N_2O_2)_2.H_2SO_4$, a solution of the acid sulphate is divided into two equal portions: one of these portions is precipitated by ammonia, and the precipitate is added to the other part of the solution and the mixture boiled. On cooling, the liquid deposits the neutral salt in transparent prisms containing 5 mols. of H_2O. The crystals become anhydrous at 200° C. (392° F.). By the spontaneous evaporation of an aqueous solution of the salt, transparent pyramids belonging to the quadratic system are obtained. According to Rammelsburg, these crystals contain 6 mols. of H_2O. (*Ber. d. Deutsch. Chem. Ges.*, 1881, p. 1231; *N. R.*, Jan. 1882.)

This salt is in "colorless or white, prismatic crystals, odorless, and having an intensely bitter taste perceptible even in highly dilute (1 in 700000) solution. Efflorescent in dry air. Soluble, at 15° C. (59° F.), in 50 parts of water, and in 109 parts of alcohol; in 2 parts of boiling water, and in 8·5 parts of boiling alcohol. Almost insoluble in ether. When heated at 100° C. (212° F.), the salt slowly loses its water of crystallization (10·51 per cent.); more rapidly when heated at 110° C. (230° F.). When quickly heated to 200° C. (392° F.), the salt fuses. Upon ignition, it is consumed, leaving no residue. On adding potassium or sodium hydrate test-solution to an aqueous solution of the salt, a white precipitate is thrown down, which is insoluble in an excess of the alkali, and which should conform to the reactions and tests of strychnine (see *Strychnina*). Barium chloride test-solution added to the aqueous solution throws down a white precipitate insoluble in hydrochloric acid. On dissolving 0·05 Gm. of Strychnine Sulphate in 2 C.c. of nitric acid (specific gravity 1·300), in a small test-tube, the acid should not turn more than faintly yellow (limit of *brucine*)." *U. S.* The chief advantage of this

* Strychnine should never be prescribed in liquid form in combination with bromides, iodides, or chlorides, for fear of forming the insoluble strychnine hydrobromate, hydriodate, or hydrochlorate. Several cases of poisoning have occurred through neglect of this precaution. Dr. A. B. Lyons (*A. J. P.*, Oct. 1877) records a case of poisoning through the patient's receiving in the last dose the greater portion of the strychnine hydrobromate, which had crystallized out.

† *Strychniæ Sulphas.* "Take of Strychnia *a troyounce;* Diluted Sulphuric Acid *nine fluidrachms,* or *a sufficient quantity;* Distilled Water *a pint.* Mix the Strychnia with the Distilled Water, heat the mixture gently, and gradually add Diluted Sulphuric Acid until the alkaloid is neutralized and dissolved. Filter the solution, and evaporate with a moderate heat, so that crystals may form on cooling. Lastly, having drained the crystals, dry them rapidly on bibulous paper, and keep them in a well-stopped bottle." *U. S.* 1870.

preparation over strychnine is its much greater solubility in water, by which it is better adapted to external use, as for application to blistered surfaces, or for hypodermic injection, or as an ingredient in collyria. These advantages may be easily gained, however, by adding a few drops of an acid—the acetic, for example—to strychnine, so that the value of this as a distinct official preparation is diminished. Owing to the presence of sulphuric acid and water of crystallization in this salt, it contains but about 75 per cent. of strychnine, and the dose would be therefore greater than that of the alkaloid.*

STYRAX. U. S. (Br.) Storax.

(STĪ'RĂX.)

"A balsam prepared from the inner bark of Liquidambar orientalis, Miller (nat. ord. Hamamelaceæ)." *U. S.* "A balsam obtained from the trunk of Liquidambar orientalis, Miller, and purified by solution in ethylic alcohol, filtration, and evaporation of the solvent." *Br.*

Styrax Præparatus, *Br.;* Prepared Storax; Styrax Liquidus, *P. G.;* Balsamum Storacis; Liquid Storax; Storax, Styrax liquide, *Fr.;* Flüssiger Storax, *G.;* Storace, *It.;* Estoraque, *Sp.*

All species of the genus Liquidambar as well as those of a related genus, Altingia, yield storax. The product most valued, however, is that obtained from *L. orientalis*, Miller.

Liquidambar orientalis. Miller, *Gard. Dict.* (1768) 8th ed. No. 2; *B. & T.* 107. The *oriental sweet-gum* is a tree from twenty to forty feet high. The palmate leaves have each of their divisions obscurely three-lobed, and are serrate, perfectly smooth, bright green and shining on the upper and pale on the under surface. The tree is a native of Asia Minor, in the southwestern parts of which it forms large forests. It yields the so-called *liquid storax.*

According to the researches of Moeller, storax is a pathological rather than a physiological product; when the young wood is injured secretion reservoirs are formed in which the storax is produced. (*Oesterr. Zeitschr.*, l.) Accounts somewhat differ as to the mode of collecting the balsam. They agree, however in the point that, the outer bark having been removed, the inner bark is scraped off and submitted to pressure. According to Mr. Maltass, the bark is first pressed cold in horse-hair bags, after which hot water is thrown over the bags and they are again pressed. Lieutenant Campbell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the drug known in commerce as *Storax bark* or *Cortex Thymiamatis.* (Hanbury, *P. J. Tr.*, xvi. 463.) The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

Several kinds of storax have been described. The purest was the *storax in grains*, which was in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called *styrax calamita*, from the circumstance, it is supposed, that it was brought wrapped in the leaves of

* *Strychnine Arsenite* having been proposed as a remedy by Prof. Grimelli, of Modena, M. Chiappero, of Turin, undertook to prepare the salt. For this purpose he dissolved arsenous acid in water acidulated with hydrochloric acid, and neutralized the arsenous acid with strychnine. But, according to M. T. Ceresoli, of Paris, the result was a mixture of strychnine arsenite and hydrochlorate. The latter chemist prepares a pure strychnine arsenite in the following manner. He takes 3·12 grammes of caustic potassa, 3·30 of arsenous acid, and 40·00 of distilled water. Having dissolved the potassa in the water, boiling hot, he adds the arsenous acid, which is completely dissolved. He then dilutes 2·65 grammes of monohydrated sulphuric acid with 20 grammes of distilled water, and, having heated the mixture to ebullition, adds 12 grammes of pure crystallized strychnine, which is entirely dissolved. The two solutions being kept at about the temperature of 100° F., he pours the arsenical solution into that of strychnine. A grumous mass is produced, much of which, however, is dissolved by heat. The liquid being filtered boiling hot from the undissolved mass, which consists almost exclusively of potassium sulphate, the filtered liquid is evaporated nearly to dryness, and the residue dissolved in absolute alcohol, by which the potassium sulphate is all left behind. The undissolved mass, after the first filtration, is repeatedly washed with alcohol; and the alcoholic solutions are mixed, concentrated, and set aside to crystallize. At the end of two days the arsenite separates in the form of cubic crystals.

Strychnine arsenite is in white cubic crystals, containing water, which they lose in contact with the air, becoming almost efflorescent. They are completely decomposed by heat, with an empyreumatic smell, and leave nothing but a black and porous charcoal. Towards the end of the vaporization, dense white vapors rise with the alliaceous smell of arsenic. The taste is bitter and metallic. Strychnine arsenite is soluble in 35 parts of cold and 10 of boiling water; is soluble also in alcohol, and less so in ether. Its formula is $(C_{21}H_{22}N_2O_2)As_2O_3$. Though scarcely yet employed, at least to any considerable extent, as a medicine, it would seem, from its constituents, to be likely to fulfil important indications, and has the advantage of a uniform composition. Consisting of two ingredients, each of which is perhaps scarcely inferior, as a remedy in intermittent fever, to any other except cinchona and its derivatives, it probably possesses strong antiperiodic powers, and might very properly be the subject of trial in any intermittent disease which proves rebellious to quinine,—the prescriber, however, being always on his guard against its poisonous action. Its commencing dose should not be larger than the smallest dose of strychnine. (*Journ. de Pharm.*, 4e sér., i. 343.)

a kind of reed, consisted of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which was a brown or reddish matter. The French call it *storax amygdaloïde*. This and the preceding variety had a pleasant odor like that of vanilla. Neither of them, however, is now found in the markets. It is probable that one or both of these varieties may have been the product of *Styrax officinale*. A third variety, which is sometimes sold as the *styrax calamita*, is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of styracin. It evidently consists of sawdust, united with a portion of the balsam. As found in commerce, it is usually in the state of a coarse, soft, dark-colored powder, mingled with occasional light friable lumps of various magnitude, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid having the odor of storax. Mr. Hanbury states that some of this variety is prepared at Trieste, Venice, and Marseilles, by mixing the residue of the liquidambar bark remaining after expression, and reduced to coarse powder, with genuine liquid storax. (*P. J. Tr.*, April, 1863.)* A fourth variety, which, under the name of *liquid storax*, is the one commonly used, is a semi-fluid, adhesive substance, brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray color within, and of an odor somewhat like that of Peruvian balsam, though less agreeable. It is kept in jars.

The storax used by pharmacists should correspond to the following official directions and tests. "A semi-liquid, gray, sticky, opaque mass, depositing, on standing, a heavier, dark-brown stratum; transparent in thin layers, and having an agreeable odor and a balsamic taste. Insoluble in water, but completely soluble (with the exception of accidental impurities) in an equal weight of warm alcohol. If the alcoholic solution, which has an acid reaction, be cooled, filtered, and evaporated, it should leave not less than 70 per cent. of the original weight of the balsam, in the form of a brown, semi-liquid residue, almost completely soluble in ether and in carbon disulphide, but insoluble in benzin. When heated on a water-bath, Storax becomes more fluid, and if it be then agitated with warm benzin, the supernatant liquid, on being decanted and allowed to cool, will be colorless, and will deposit white crystals of cinnamic acid and cinnamic ethers." *U. S.* "Heated in a test-tube placed in boiling water, it becomes more liquid, but gives off no moisture; boiled with *solution of potassium bichromate* and *sulphuric acid*, it evolves an odor resembling that of essential oil of bitter almonds." *Br.*

As found in commerce, storax is usually so much adulterated as to require purification before it can be used; and in both Pharmacopœias processes were formerly given. Whenever not originally pure enough for use, it should be dissolved in alcohol, the solution strained, and the alcohol distilled off to a certain extent, and then completely evaporated at a gentle heat. Among the substances used in the adulteration of storax is turpentine. To detect it Dr. Hager employed the following method. He liquefied the resin, in a tube, by means of a water-bath, added half its volume of absolute alcohol, and hastened the solution by agitation; he then treated it with several volumes of benzin. This operation was repeated twice. The liquors obtained were then evaporated, in a tared vessel; and there was obtained, for pure storax, a colorless residue (45 to 55 per cent.), with a light-blue opalescence; for that mixed with turpentine, a residue more considerable, yellowish, and having the terebinthinate odor. (*Journ. de Pharm.*, Fév. 1876, p. 161.)

General Properties. Storax has a fragrant odor and an aromatic taste. It melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light, spongy, carbonaceous residue. It imparts its odor to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Neumann obtained from 480 grains of storax 120 of aqueous extract, and from an equal quantity 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to rank as a balsam.

The most abundant constituent of storax is probably *storesin*, $C_{36}H_{55}(OH)_3$, discovered

* The *Liquidambar styraciflua*, or Sweet Gum of our Southern States, was at one time thought to be the source of storax. Its geographical range reaches into Mexico, and it yields a storax-like product in an abundance proportionate to the heat of the climate. A specimen from Guatemala is described by Flückiger and Hanbury as a yellow, opaque resin, of honey-like consistence, becoming transparent, amber-colored, and brittle by exposure to the air, and having a rather terebinthinous balsamic odor and but little taste. Sometimes it occurs as a thick golden-brown fluid. It contains cinnamic acid and styracin. (*A. J. P.*, 1874, p. 161.) It is soluble in alcohol, and has been gathered to a considerable extent in the United States for the preparation of chewing-gum. The resins of *Liquidambar formosana* and *L. altingiana* are known in Eastern commerce. Dr. Carl Mohr describes in *Pharm. Rund.*, 1895, 57, the collection of *American storax* in the Missisippi States.

in 1877 by W. von Miller. This is present both free and in the form of a cinnamic ether. Storesin is an amorphous substance, melting at 168° C. (334·4° F.), readily soluble in benzin. *Cinnamic ethers of phenyl-propyl, cinnamic ether of ethyl, cinnamic ether of benzyl*, and especially *cinnamate of cinnamyl*, $C_9H_7O_2.C_9H_9$, the so-called *styracin* of Bonastre, have also been observed. This last compound can be removed by ether, benzol, or alcohol after the separation from the resin of the cinnamic acid; it is insoluble in water, and volatile only in superheated steam. It crystallizes in tufts of long rectangular prisms, which melt at 38° C. (100·4° F.), but frequently does not solidify readily. By concentrated solution of potash, it is resolved into a cinnamate and cinnamic alcohol (*styrone*), $C_9H_{10}O$, which latter is not present in liquid storax. The yield of *cinnamic acid** varies from 6 to 12 per cent., or even, according to Löwe, as much as 23 per cent. of crystallized cinnamic acid can be obtained. The acid dissolves abundantly in ether, alcohol, or hot water, slightly in cold water; it is inodorous, but has an acrid taste. It fuses at 133° C. (276·4° F.), and boils at 290° C. (554° F.). Another minor constituent of storax is a fragrant substance melting at 65° C., and possessing the odor of vanillin (ethyl-vanillin?), which Rump (*Ber. der Chem. Ges.*, 1878, 1034) identified. Miller also shows that water removes from the drug a little free benzoic acid. There is further found in liquid storax a hydrocarbon, C_8H_8, first prepared by Simon in 1839, which exists in the resin as a liquid, and also in a polymeric form as a solid. The former, called *styrol* or *cinnamene*, has a sp. gr. of 0·924, and a boiling point of 146° C. (294·8° F.). It is a colorless, mobile liquid, possessing the odor and burning taste of liquid storax. It has since been formed synthetically, and has been recognized as *phenylethylene*, $C_6H_5.CH = CH_2$. When heated for a considerable time to 100° C. (212° F.), or for a shorter period to 200° C. (392° F.), it is converted without change of composition into the colorless, transparent solid *metastyrol*, which, unlike styrol, is not soluble in alcohol or in ether. Lastly, there has been found in liquid storax, by J. H. van t'Hoff (1876), about 0·4 per cent. of a pleasant-smelling lævo-rotatory oil of the formula $C_{10}H_{16}O$. (*Pharmacographia*, 2d ed., 274 and 275.)

Medical Properties and Uses. This balsam is a stimulating expectorant, and was formerly recommended in *phthisis*, *chronic catarrh*, *asthma*, and *amenorrhœa;* but it is very seldom used at present, except as a constituent of the compound tincture of benzoin. Liquid storax has been recommended in *gonorrhœa* and *leucorrhœa* as equally effectual with copaiba, and less disagreeable. From ten to twenty grains (0·65–1·3 Gm.) may be given twice a day, and the dose gradually increased. The same variety of storax, mixed with olive oil, has been found by Dr. H. Schultze, of Magdeburg, effectual in the cure of *itch*, the death of the insect resulting from a single thorough rubbing of the surface in twenty-four hours. (*Am. Journ. Med. Sci.*, July, 1867.) The statements of Prof. Landerer, that the cinnamic acid obtained from storax injected into the cephalic vein (from five to twelve drops of the 5 per cent. emulsion, with the oil of almonds and yolk of egg, rendered alkaline) is a specific in *phthisis*, has not been confirmed by subsequent studies. (*Med. Chron.*, 1895.)

SUCCI. Juices.

(sŭc'cī—sūk'sī.)

Though introduced to professional notice by Mr. Squire so long since as in the year 1835, and subsequently used by many practitioners, the Juices were recognized but once by the U. S. Pharmacopœia (1870). They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and of course the uncertainty in operation, of the fresh juices themselves, varying according to the soil, climate, mode of cultivation, season, and the age of the plant, it may be questioned whether they merit the prominence which has been given them in the British Pharmacopœia.

* *Cinnamic acid* has recently attracted attention as a germicide. Classon recommends the following process for its preparation. Storax is boiled with solution of sodium carbonate, the mixture is allowed to cool, and hydrochloric acid is added to neutralize the greater portion of the excess of alkali, leaving the mixture faintly alkaline. It is then again boiled, allowed to cool, and filtered, the residue on the filter being washed with water. The filtrate and washings are concentrated, if necessary, and precipitated with excess of hydrochloric acid: the precipitate is collected on a filter, washed with a little water, and dried. The crude cinnamic acid so obtained is purified by crystallization from hot benzin. It is made more cheaply now synthetically, and is obtained as a by-product in the preparation of benzaldehyde. It is claimed for it that it is a non-poisonous antiseptic, and Landerer (*Die Behandlung der Tuberkulose*, etc., Leipzig, 1892) has found it in *phthisis* a very valuable, though not specific, medicament, which may be even used intravenously without injury. In *lupus* and other surgical forms of *tuberculosis* he injects it into the part.

SUCCUS BELLADONNÆ. Br. Juice of Belladonna.

(SŬC'CŲS BĔL-LĄ-DŎN'NÆ.)

"Bruise the fresh leaves and young branches of Atropa Belladonna, Linn.; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, from five to fifteen minims (0·3–0·9 C.c.).

SUCCUS CONII. Br. Juice of Conium.

(SŬC'CŲS CŌ-NĪ'Ī.)

Suc de grande Ciguë, *Fr.;* Schierlingsaft, *G.*

"Bruise the fresh leaves and young branches of Conium maculatum, Linn.; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

The albumen is probably coagulated under the influence of the alcohol; and hence the propriety of directing filtration. The dose of this preparation is from thirty to sixty minims (1·9–3·7 C.c.).

The experiments of Dr. John Harley (*A. J. P.*, 1867, 363) seemed to indicate that the juice is the best preparation of conium. He found that one fluidounce of it contained 0·42 grain of the alkaloid, and that five and a half fluidrachms of it produced very severe and characteristic symptoms. Subsequent experience has shown, however, that Succus Conii, at least as it reaches Philadelphia, is even in the best brands a very uncertain preparation, distinctly inferior in every way to the U. S. fluid extract made from the green fruit. (See *Year-Book of Pharmacy*, 1896, 292.) One fluidrachm (3·7 C.c.) may be given at a dose, and rapidly increased until some effects are produced.

SUCCUS HYOSCYAMI. Br. Juice of Hyoscyamus.

(SŬC'CŲS HĪ-ŌS-CĪ'Ą-MĪ.)

"Bruise the fresh leaves, flowering tops, and young branches of Hyoscyamus niger, Linn.; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

The dose of this preserved juice is from one-half to one fluidrachm (1·9–3·7 C.c.).

SUCCUS SCOPARII. Br. Juice of Broom.

(SŬC'CŲS SCŌ-PĀ'RĮ-Ī.)

Suc de Genêt à Balais, *Fr.;* Besenginstersaft, *G.*

"Bruise fresh Broom Tops; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

The dose of this preparation as a diuretic is from one to two fluidrachms (3·7–7·5 C.c.). In large doses it would be apt to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone.

SUCCUS TARAXACI. Br. Juice of Taraxacum.

(SŬC'CŲS TĄ-RĂX'Ą-CĪ.)

Suc de Pissenlit, *Fr.;* Löwenzahnwurzelsaft, *G.*

"Bruise fresh Taraxacum Root; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

The dose of this juice is from two fluidrachms to half a fluidounce (7·5–15 C.c.).*

SULPHONAL. Br. Sulphonal.

$C_7H_{16}S_2O_4$. (SŬL'PHŌ-NĂL.) $(CH_3)_2C(SO_2C_2H_5)_2$.

"Sulphonal, or dimethyl-methane-diethylsulphone, $(CH_3)_2C(SO_2C_2H_5)_2$, is a product of the oxidation of mercaptol, $(CH_3)_2C(SC_2H_5)_2$, obtained from acetone and mercaptan." *Br.*

Diethylsulphon-dimethyl-methane.

* *Procter's Preserved Juice of Taraxacum.* Of the fresh roots collected in September or October, twenty pounds avoirdupois are to be sliced transversely, reduced to a pulpy mass by grinding or contusion, then thoroughly incorporated with four pints of alcohol of 0·835, and set aside in stone-ware jars. After a week, or a longer time, the pulpy mass is to be subjected to strong pressure, and the liquor filtered and bottled for use. Even after six months the pulp thus treated preserves the sensible properties of the dandelion in a marked degree. Should the alcohol in the expressed liquor be objected to, it may be partially removed by evaporation by means of a water-bath until the bulk of the juice has been diminished one-sixth, and then adding eight ounces of sugar for every pint. (*A. J. P.*, xxv.)

Sulphonal was not introduced into the U. S. P. 1890, because its manufacture is limited by law to the firm that owns the process. Sulphonal belongs to the class of disulphones, to which belong also Trional and Tetronal. (See *Trional* and *Tetronal*, PART II.) It may be made by the following processes. When anhydrous mercaptan (ethyl sulphydrate) and anhydrous acetone are mixed and a stream of dry hydrochloric acid gas passed through, the liquid gradually becomes turbid and separates into two layers, the upper being mercaptol (dithioethyldimethylmethane), the lower, diluted hydrochloric acid. The mercaptol is separated, washed, and then oxidized with potassium permanganate, the liberated oxygen converting the mercaptol into sulphonal. It may also be prepared by the action of ethyl chloride on sodium thiosulphate, the resulting sodium ethyl thiosulphate being converted into ethyl mercaptan and acid sodium sulphate by the action of water. This conversion is made to take place in the presence of alcohol, hydrochloric acid, and acetone, the ethyl mercaptan being condensed to mercaptol, which is oxidized by potassium permanganate, sulphonal being the result. It forms heavy colorless prismatic crystals, melting at 125·5° C., which are not very soluble in cold water, but more readily in boiling water, and in alcohol and alcoholic ether. A characteristic test is to fuse the sulphonal in a small dry test-tube, heat to about 280° C., and to the clear liquid add pyrogallic (or gallic) acid. The liquid becomes brown and gives off the characteristic odor of mercaptan or sulphur alcohol. Heating with potassium cyanide or even with powdered charcoal will effect the same decomposition. The British Pharmacopœia gives the following description: "Colorless, inodorous, nearly tasteless prismatic crystals; without action on *litmus;* melting at 258° F. (125·5° C.). Soluble in 15 parts of boiling *water*, in 450 parts of cold *water*, in 50 parts of cold *alcohol* (90 per cent.), very soluble in boiling *alcohol* (90 per cent.), soluble in *ether*. Heated to redness with free access of air, it burns, evolving sulphurous anhydride, and leaving no residue (absence of mineral impurity). If a mixture of Sulphonal with an equal weight of *potassium cyanide* be heated, the odor of mercaptan is evolved, and when to the solution of the product in *water* excess of *hydrochloric acid* and a few drops of *test-solution of ferric chloride* are added, a reddish color is developed. It evolves hydrogen sulphide when gradually warmed with dried *sodium acetate*. It should yield no characteristic reaction with the tests for chlorides or sulphates."

Medical Properties and Uses. In the lower animals sulphonal produces sleep, which, if the dose has been sufficiently large, deepens into coma accompanied by paresis, tremors, and convulsions. Occasionally loss of power in the hind legs notably precedes the cerebral symptoms. The action of the drug upon the circulation seems to be very feeble, although it has not been thoroughly made out. According to Schick, the nerves and the muscles are not altered, so that the symptoms must be centric in origin. Kast found that the blood is not changed, and, according to Dr. W. J. Smith, tissue-change is not influenced. When sulphonal is given to human beings in doses of from fifteen to thirty grains, sleep usually develops in from half an hour to an hour, in most cases gradually, sometimes with remarkable abruptness. It is usually quiet, and not followed by disagreeable after-effects, although sometimes mental confusion and lassitude remain. Over pain sulphonal exerts no influence. It was originally asserted by Prof. Kast that the drug would prove especially useful in *insomnia* from cardiac diseases, but further experience does not sustain this. Occasionally sulphonal produces nausea, vomiting, gastric pain, diarrhœa, languor, headache, depression, ataxic symptoms, especially loss of power in the legs, mental disturbance, etc. These disagreeable effects are, however, rare after the single dose, but are much more apt to follow the continuous use of the remedy, there being evidently some tendency for sulphonal to accumulate in the system, as noticed by Jastrowitz, Bresslauer, and others. (See, also, *Internat. Klin. Rundsch.*, Nov. 1891.)

It is usually after the continued use of the drug that the rubeolous or scarlatinous exanthem appears. A number of cases of poisoning by large doses or the continuous use of sulphonal have been reported. (*Lancet*, April, 1891; *Med. Rec.*, Dec. 1890; *Therap. Monatschr.*, Dec. 1888; *Deutsche Med. Wochenschr.*, May, 1891; *Med. News*, Aug. 1889, cause of death somewhat doubtful; *Brit. Med. Journ.*, Oct. 1890.) The symptoms in these cases have been extraordinarily prolonged sleep, lasting for a number of days, with comparatively little disturbance of the circulation or the breathing (unless the dose has been extraordinarily large and a late stage of the poisoning is considered); marked ataxic disturbance of speech and gait; a peculiar exanthem, which is prone to be symmetrical; ptosis, with normal or dilated and fixed pupils; paralysis of the sphincters; renal disturbance; fall of temperature.

Professor Kast found that under the influence of large doses of sulphonal there was no increase in the elimination of sulphur, and came to the conclusion that the sulphonal was eliminated in

the form of a highly soluble organic compound, probably a sulphonic acid. Jaffe and Jolles have, however, each obtained unaltered sulphonal from the urine of persons poisoned by it; but it seems positive that only a small proportion of sulphonal escapes unchanged, and from the researches of Dr. W. J. Smith it would appear probable that the sulphonal splits up in the system so as to yield ethylsulphonic acid, which escapes unchanged in the urine.

Upon the kidneys sulphonal seems to act, when in sufficient amount, as an irritant, though after the ordinary therapeutic dose no pronounced renal symptoms are apparent. Aching pains in the loins and pronounced diuresis are not rarely present after overdoses, and in poisoning by the drug the urine frequently becomes of a dark port-wine color, staining the linen of the patient where it falls, and containing, according to the researches of the Swedish physiologist Hammarsteen, *hæmatoporphyrine*. Complete arrest of the renal secretion has occurred in some cases; the presence of this symptom makes the prognosis very grave. Whenever sulphonal is given largely or for a length of time, the urine should be carefully watched, and any smoky or dark appearance of the excretion should be the signal for the immediate withdrawal of the drug. That enormous doses of sulphonal may be recovered from is shown by the case reported by Neisser, in which over three ounces are said to have been taken, six hours elapsing before any medical treatment was instituted. In the case reported by Knaggs, four hundred and fifty grains produced death after unconsciousness lasting for three days, with complete anuria. The dose of sulphonal is from ten to forty grains (0·65–2·59 Gm.), which should always be given in fine powder, compressed pills frequently passing through the bowels unchanged.

SULPHURIS IODIDUM. U. S., Br. Sulphur Iodide.

(SŬL'PHŬ-RĬS Ī-ŌD'Ĭ-DŬM.)

Sulfur Iodatum, *P. G.;* Ioduretum Sulfuris, *F. P.;* Iodure de Soufre, *Fr.;* Jodschwefel, *G.*

"Washed Sulphur, *twenty grammes* [or 308 grains]; Iodine, *eighty grammes* [or 2 ounces av., 360 grains]. Mix the Washed Sulphur and Iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and, by means of a water-bath, gradually and with occasional agitation apply a heat not exceeding 60° C. (140° F.), until the ingredients combine, and become of a uniformly dark color throughout. Then increase the heat to the boiling point of the water, so as to fuse the mass. Should any Iodine have sublimed and condensed on the glass, incline the flask so as to combine the Iodine with the fused mass, and then pour the latter out upon a porcelain plate or other suitable cold surface. After cooling break the product into pieces of suitable size, and keep them in a glass-stoppered bottle, in a cool place." *U. S.*

"Iodine, 4 *ounces* (Imperial) or 100 grammes; Sublimed Sulphur, 1 *ounce* (Imp.) or 25 grammes. Intimately mix the Sublimed Sulphur with the Iodine; heat the mixture gently in a loosely corked flask; when the mass becomes uniformly dark, increase the temperature so as to produce liquefaction; allow the product to cool in the flask. The flask should then be broken, and the solidified mass of Sulphur Iodide reduced to fragments, which should be kept in a well-closed vessel." *Br.*

Both of the official processes were derived from the French Codex. Though formerly official with the London and Dublin Colleges, it was omitted in the first British Pharmacopœia, to be resumed in the present. It simply effects a combination of the two elements by melting them together.

Properties. Sulphur iodide is in "brittle masses of a crystalline fracture and a grayish-black, metallic lustre, having the odor of iodine, and a somewhat acrid taste. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol and ether dissolve out the iodine, leaving the sulphur. Continued boiling with water vaporizes all the iodine, leaving about 20 per cent. of sulphur as residue. On exposing Sulphur Iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature a sublimate is formed, containing both iodine and sulphur. At a still higher temperature the whole is volatilized, leaving only a trace of residue." *U. S.* "A grayish-black solid substance, with a radiate crystalline appearance. It resembles iodine in smell, and in the property of staining the skin. Soluble in 60 parts of *glycerin;* insoluble in cold *water*. When boiled with *water* the iodine passes off in vapor, and the sulphur remains as an insoluble residue having about one-fifth of the weight of the Sulphur Iodide taken." *Br.* This compound is chemically regarded as *iodine disulphide*, I_2S_2, or, as sometimes stated, *sulphur subiodide*. Its solution in glycerin would probably prove useful, in some cases, as a substitute for the ointment of this iodide. It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapors of iodine

being evolved, and the smell of sulphur perceived. (Dr. G. W. Patterson.) This result renders it doubtful whether the so-called sulphur iodide is really a distinct chemical compound formed according to the laws of chemical combination, or is a mere physical mixture. Sulphur iodide has been very usefully employed as an external remedy in various skin diseases, such as *tinea capitis*, *lupus*, *lepra*, etc., applied in the form of ointment. (See *Unguentum Sulphuris Iodidi*.) Internally, it has been used with alleged great advantage in human *glanders*. (M. Bourdon, of Paris, *Ann. de Thérap.*, 1858, 239.)

SULPHUR LOTUM. U. S. Washed Sulphur.

S; 31·98. (SŬL'FHŬR LŌ'TŬM.) S; 32.

Sulphur Depuratum, s. Flores Sulphuris Loti, *P. G.;* Soufre lavé, *Fr.;* Gereinigte Schwefelblumen, *G.*

"Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, *ten cubic centimeters* [or 162 minims]; Water, *a sufficient quantity*. Pass the Sublimed Sulphur through a No. 30 sieve, mix it thoroughly with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, add *ten cubic centimeters* [or 162 minims] of Ammonia Water, and digest for three days, agitating occasionally. Then add *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, transfer the mixture to a muslin strainer, and wash the Sulphur with Water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat, and pass it through a No. 30 sieve." *U. S.*

Sublimed sulphur is frequently contaminated with small quantities of sulphuric acid and other impurities, and the object of the ammonia in the above process is to neutralize the acid, the salt being subsequently washed out. (See *Sulphur Sublimatum*.)

Properties. "A fine yellow powder, without odor or taste. Insoluble in water; slightly soluble in absolute alcohol; more readily soluble in benzin, benzol, oil of turpentine, and many other oils; also in ether, in chloroform, and in boiling, aqueous solutions of alkaline hydrates. Carbon disulphide promptly dissolves a portion of it, but leaves a residue of insoluble sulphur, which may be dissolved by a boiling solution of an alkaline hydrate. When heated to 115° C. (239° F.), Washed Sulphur melts, and at a higher temperature volatilizes, or, if air be admitted, burns to sulphur dioxide, which is identified by its characteristic odor, and by its blackening a strip of paper moistened with mercurous nitrate test-solution held in the gas. The amount of residue left after volatilizing or igniting a weighed portion of it should not exceed 0·5 per cent. If 0·5 Gm. of Washed Sulphur be boiled with 10 C.c. of sodium hydrate test-solution, it should be completely dissolved, leaving no residue (absence of *earthy* or *metallic impurities*). If 0·5 Gm. of Washed Sulphur be digested for several hours with 10 C.c. of ammonia water, the clear filtrate should not be colored yellow, nor be rendered turbid, by acidulation with hydrochloric acid, even after the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*). If 5 C.c. of water be agitated with 2 Gm. of Washed Sulphur, the liquid should not change the color of blue or red litmus paper (absence of *acid*, and of *ammonia*). If 0·5 Gm. of Washed Sulphur be boiled with a solution of 0·5 Gm. of potassium cynanide in 5 C.c. of water, and, after filtration, the clear liquid be acidulated with hydrochloric acid, it should not assume a reddish color, even after standing for an hour (absence of *selenium*)." *U. S.* The dose is from half a drachm to half an ounce (1·9–15·5 Gm.).

SULPHUR PRÆCIPITATUM. U. S., Br. Precipitated Sulphur.

[Milk of Sulphur. Br.]

S; 31·98. (SŬL'FHŬR PRÆ-CĬP-Ĭ-TĀ'TŬM.) S; 32.

"Sulphur precipitated by hydrochloric acid from a solution of calcium sulphides and thiosulphate, which has been made by boiling together sulphur and lime in water." *Br.*

Lac Sulphuris; Milk of Sulphur; Magisterium Sulphuris; Soufre précipité, Lait de Soufre, *Fr.;* Schwefelmilch, *G.*

"Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Lime, *fifty grammes* [or 1 ounce av., 334 grains]; Hydrochloric Acid, Water, each, *a sufficient quantity*. Slake the Lime, and mix it uniformly with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water. Add the Sublimed Sulphur, previously sifted, and, after thorough mixing, add *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Water, and boil the mixture during one hour, stirring constantly, and replacing the Water lost by evaporation. Then cover

the vessel, and permit the contents to cool and to become clear by subsidence. Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually, and with constant stirring, Hydrochloric Acid, previously diluted with an equal volume of Water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it, until the washings are tasteless and cease to give an acid reaction with litmus paper. Then dry the product rapidly, at a moderate heat, and keep it in well-stoppered bottles." *U. S.*

The process for precipitated sulphur was not much changed in the last revision: the quantity of lime was, however, diminished, which is an improvement, as the excess of lime caused loss in filtration unless great care was taken to wash the precipitate well. The Br. Pharm. in its official definition outlines the method used in the U. S. preparation.

In the U. S. process three molecules of calcium oxide react with six atoms of sulphur to form two mols. of calcium disulphide and one of calcium thiosulphate (hyposulphite): $3CaO + (S_2)_3 = 2CaS_2 + CaS_2O_3$. On the addition of the hydrochloric acid, six atoms of sulphur are precipitated (four from the two mols. of calcium disulphide and two from the one mol. of calcium hyposulphite), and the calcium and oxygen unite with the hydrochloric acid, so as to form calcium chloride and water, according to the reaction $2CaS_2 + CaS_2O_3 + 6HCl = 3CaCl_2 + 3H_2O + (S_2)_3$. This rationale is not exactly applicable to the British process, in which the proportion of the sulphur to the lime employed is greater than in that of the U. S. Pharmacopœia, and on account of this greater excess of sulphur the reaction takes place as follows: $3CaO + (S_2)_6 = 2CaS_5 + CaS_2O_3$, a calcium pentasulphide being formed. Hydrochloric acid is the most eligible precipitant for the sulphur, as it gives rise to calcium chloride, which is a very soluble salt and is easily washed away. Sulphuric acid is wholly inadmissible, as it generates calcium sulphate, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which to precipitate the sulphur is potassium sulphide, formed by boiling sulphur with caustic potassa. Dr. Otto, of Brunswick, finds that potassium sulphide is apt to contain copper sulphide, and therefore he prefers calcium sulphide.

Properties. Precipitated sulphur is in friable lumps, of a white color, with a pale yellowish-green tint, and consisting of finely divided particles slightly cohering, or, as officially described, is "a fine, amorphous powder, of a pale yellow color, without odor or taste. Insoluble in water; very slightly soluble in absolute alcohol; readily soluble in carbon disulphide; also in benzin, benzol, oil of turpentine, and many other oils; also in ether, in chloroform, and in boiling, aqueous solutions of alkaline hydrates. At 115° C. (239° F.) Precipitated Sulphur melts, and at a higher temperature it volatilizes, or, if air be admitted, burns to sulphur dioxide, leaving no residue. If 0·5 Gm. of Precipitated Sulphur be boiled with 10 C.c. of sodium hydrate test-solution, it should be completely dissolved, leaving no residue (absence of *earthy* or *metallic impurities*). If 1 Gm. of Precipitated Sulphur be digested for several hours with 10 C.c. of ammonia water, a portion of the clear filtrate should not leave any residue on evaporation; nor should another portion be colored yellow, or rendered turbid, by acidulation with hydrochloric acid, even after the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*). If 5 C.c. of water be agitated with 2 Gm. of Precipitated Sulphur, the liquid should not change the color of blue or red litmus paper (absence of *acid* or *alkali*); nor should it leave any residue on evaporation (absence of *soluble impurities*). If 0·5 Gm. of Precipitated Sulphur be boiled with a solution of 0·5 Gm. of potassium cyanide in 5 C.c. of water, and, after filtration, the clear liquid be acidulated with hydrochloric acid, it should not assume a reddish color, even after standing for an hour (absence of *selenium*)." *U. S.* For a paper on Selenium in Sulphur by Dr. T. D. Reed, see *Proc. A. P. A.*, 1897, 251. "A grayish-yellow soft powder, free from grittiness and from the smell of hydrogen sulphide. Under the microscope it is seen to consist of opaque globules, without any admixture of crystalline matter. It responds to the chemical tests mentioned under 'Sulphur Sublimatum.'" *Br.* The German test, that 1 Gm. of precipitated sulphur should dissolve in 5 Gm. of carbon disulphide, is trustworthy, according to Fittinger. Precipitated sulphur is entirely dissipated by heat; water boiled with it should not redden litmus. When recently prepared, it is devoid of taste, but possesses a peculiar smell. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. From its color it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of caustic potassa, and in oil of turpentine by the aid of heat. When of a brilliant white color, the presence of calcium sulphate may be suspected; in which case the preparation will not be

wholly volatilized by heat. If pure, it communicates a harsh feel when rubbed between the fingers, owing to the friction of the particles. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon the presence of water, which, however, is found in too small a quantity to constitute a regular *hydrate*. According to Rose, its white color is occasioned by the presence of a small proportion of hydrogen sulphide. Soubeiran states that it always contains some hydrogen sulphide, which causes it to differ as a therapeutic agent from sublimed sulphur.

Medical Properties and Uses. Precipitated sulphur possesses medical properties similar to those of sublimed sulphur. Its state of extreme division renders it more readily suspended in liquids. It is sometimes selected for forming sulphur ointments: these have the advantages of being lighter in color and smoother than those made with sublimed sulphur. The dose is from one to three drachms (3·9–11·65 Gm.).

SULPHUR SUBLIMATUM. U. S., Br. Sublimed Sulphur.

S; 31·98. (SŬL'PHŬR SŬB-LI-MĀ'TŬM.) S; 32.

"May be prepared, more or less directly, from native sulphur or sulphides." *Br.*

Flores Sulphuris; Flowers of Sulphur; Brimstone; Soufre, Fleurs (Crême) de Soufre, *Fr.;* Schwefel, Schwefelblumen, Schwefelblüthe, *G.;* Zolfo, *It.;* Azufre, *Sp.*

Natural States. Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is particularly abundant in mustard and other cruciform plants. It occurs in the earth either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphides. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur*. The most productive mines of sulphur are found in Sicily (400 distinct sulphur workings existing there, with a present annual production of 427,906 tons) and in the former Pontifical States. In 1869 or 1870 sulphur in large masses was discovered in the volcanic island of Saba, one of the Dutch West Indies, about 110 miles south of St. Thomas. Sulphur exists as a mineral in widely separated localities and in enormous quantities in the Western United States. A large mine of native sulphur has been opened in California, about twenty miles from Santa Barbara, and seven from the sea-coast. Near the borax lake in California (see *Sodii Boras*) is an elevation, where the deposition of sulphur is constantly going on from vapors arising from innumerable crevices in a decomposed volcanic rock, the surface of which is so far covered with the deposited matter as to give the mass the appearance of a bank of sulphur. It is called "Sulphur Banks," according to Whitney. In 1872 a great hill of almost pure sulphur was found about 900 miles west of Omaha and 30 miles south of the Union Pacific Railroad. Two hundred miles south of Salt Lake City there is a deposit of sulphur two thousand feet square and of unknown thickness, shafts having been sunk sixty feet without reaching the bottom. This sulphur is said to be free from arsenic and antimony, and is a surface deposit. Much sulphur has been found in Mount Humboldt, Nevada, and Sulphur Mountain, as it is called, in the Yellowstone National Park, is largely composed of the mineral. The only localities in the United States in which sulphur is actively mined, however, are the Cove Creek Mine, Utah, and in Calcasieu Parish, La., where a sulphur deposit underlying a quicksand is being mined by the Frasch process. A double-walled iron pipe is driven through the quicksand into the sulphur bed, and steam having been sent down between the walls of the pipe, the melted sulphur is raised in the inner pipe. Sulphur exists in large quantities in various localities in Japan. It is estimated that at Atosanobori there are five million tons of superior ore. The total importations of sulphur from Sicily in 1895 amounted to 125,950 tons, valued at $1,593,148; in 1896 to 145,318 tons, valued at $2,085,076; and in 1897 to 138,846 tons, valued at $2,442,240.

An estimate of the amount of sulphur consumed in the United States during 1897 is as follows:

	Tons.
From 138,846 tons imported brimstone (98 per cent.)	136,069
From 1,690 tons domestic brimstone (98 per cent.)	1,656
From 259,546 tons imported pyrites (47 per cent.)	121,986
From 128,468 tons domestic pyrites (44 per cent.)	56,592
Total tons sulphur consumed	316,303

Extraction, etc. Sulphur is obtained either from sulphur earths or from the native iron and copper sulphides, called iron and copper pyrites. The sulphur earths are placed in earthen pots set in oblong furnaces of brick-work. From the upper and lateral part of each pot a tube proceeds obliquely downwards, which communicates with the upper part of a similar pot, situated outside the furnace, and perforated near its bottom, to allow the melted sulphur to flow into a vessel containing water, conveniently placed to receive it. Fire being applied, the sulphur rises in vapor, leaving the impurities behind, and, being condensed again, flows from the perforated pot into the vessel containing the water. Sulphur as thus obtained is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification it is generally melted in a cast-iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders about an inch in diameter, called in commerce *roll sulphur* or *cane brimstone*. The dregs of this process, ground to powder, constitute a very impure kind of sulphur, of a gray color, called in commerce *sulphur vivum* or *horse brimstone*. The above process purifies the sulphur but imperfectly. At the same time it causes a considerable loss, as the dregs just mentioned contain a large proportion of sulphur. A more eligible mode of purification consists in distilling the crude sulphur from a large cast-iron still set in brick-work over a furnace, and furnished with an iron head. The head has two lateral communications, one with a chamber of brick-work, the other with an iron receiver immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and the receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur*, or *flowers of sulphur*. If, on the other hand, the communication with the chamber be closed, and that with the receiver opened, the sulphur will condense in the latter in the fused state, and, when cast in cylindrical moulds, forms the *roll sulphur* of commerce.

The extraction of sulphur from iron bisulphide (iron pyrites) is performed by distilling it in stone-ware cylinders. Half the sulphur contained in the bisulphide is volatilized by the heat, and conducted, by means of an adapter, into vessels containing water, where it condenses. The residue of the mineral is employed for making ferrous sulphate. In the island of Anglesea, and at Swansea, Wales, large quantities of sulphur are obtained from imported Spanish copper pyrites in the process for extracting that metal. The furnaces in which the ore is roasted are connected with chambers in which the volatilized sulphur is condensed.

A process for separating pure sulphur from the residue of the manufacture of soda, proposed by Max Schaffner, has been put in operation in most of the soda-factories of Germany, and has been introduced, to a greater or less extent, in England, France, and Belgium. (See details, *A. J. P.*, 1869, p. 545.) We shall confine ourselves to an outline. The process is divided into three parts: *first*, the preparation of the *soda solution* by heaping up the soda residue in the air, whereby oxidation takes place, and polysulphides and hyposulphites are formed, which are extracted by lixiviation; *secondly*, the solution thus obtained is decomposed in close stone or iron vessels, by hydrochloric acid, which decomposes the polysulphides and hyposulphites, with precipitation of sulphur; and, *thirdly*, the sulphur is obtained pure by fusing it under water, with steam and a pressure of $1\frac{3}{4}$ atmospheres. Calcium chloride remains in solution, gypsum is suspended, and the addition of a little milk of lime neutralizes any free acid present, and with the sulphur forms calcium sulphide, which dissolves whatever arsenic sulphide may be present, leaving the sulphur free from impurities. This collects in the bottom of the kettle, and is drawn off into moulds. From 60 to 65 per cent. of pure sulphur is thus obtained from the soda residue. A. M. Chance (*Journ. Soc. Chem. Industry*, 1888, p. 162) has described a process which after several years of experiment has been perfected, and seems likely to solve definitely the problem of sulphur recovery, if, as stated, 95 per cent. of the sulphur can be recovered either as brimstone or burned in sulphur furnaces for the manufacture of sulphuric acid. Chance passes limekiln gases (carbon dioxide and nitrogen) into the vats of alkali waste, liberating thereby the sulphur as hydrogen sulphide. This mixed with nitrogen goes into another vessel of alkali waste, when H_2S and CaS unite to form $Ca(HS)_2$, a calcium sulphydrate, while the nitrogen is allowed to escape. The $Ca(HS)_2$ is now decomposed by a fresh quantity of CO_2, and thus liberates a double quantity of hydrogen sulphide. This is so pure that when mixed with the requisite quantity of air and passed over anhydrous ferric oxide at a dull red heat the hydrogen is burned, liberating the sulphur, according to the reaction $H_2S + O = H_2O + S$. The sulphur can be obtained either in the

sublimed or in the fused form, according to the temperature of the chamber. The present annual production by the Chance process in England amounts to 20,000 tons.

Crude sulphur comes to this country principally from Messina, in Sicily, and the ports of Italy. Roll sulphur and the flowers are usually brought from Marseilles. Good Sicilian sulphur does not contain more than 3 per cent. of impurity, consisting chiefly of earths. Crude sulphur is employed by the manufacturers of sulphuric acid; and, as it is very variable in quality, it becomes important to ascertain its value. This may be done by drying a given weight of it and submitting it to combustion. The weight of the incombustible residue, added to that lost in drying, gives the amount of impurity.

Properties. Sulphur is a non-metallic element, susceptible of several allotropic states. In its ordinary state it is a brittle solid, of a pale yellow color, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible smell when rubbed. When pure its sp. gr. is about 2; but it varies a little in density in its different allotropic states. Occasionally, from impurity, its sp. gr. is as high as 2·35. Its atomic weight is 31·98, and its symbol S. It is a bad conductor of heat, and becomes negatively electric by friction. The melting point of sulphur varies with its allotropic state, which is readily altered by heat. Pure sulphur melts and sublimes at 114·5° C. (238° F.). If heated above its melting point, it undergoes, in proportion to the heat applied, a progressive change, which will cause it, upon slow cooling, to solidify at a temperature lower than that at which it was melted; and if it be remelted it will be found to have a higher melting point than before. Melted sulphur is perfectly limpid, and of a bright yellow color. When sulphur is melted, and, after partial cooling, the crust formed on its surface is pierced, and the fluid portion poured out, it may be obtained in slender monoclinic crystals, constituting an allotropic condition of the element. This variety, however, gradually passes back into the more permanent variety found in nature. When sulphur is heated above its melting point, it becomes deeper-colored and less fluid. At 200° C. (392° F.) it has a deep brown color, and is so viscid that it cannot be poured from the containing vessel. If the temperature be still further increased, the sulphur resumes its fluidity, but retains its brown color. Finally, when the temperature reaches 448·4° C. (839° F.), it boils, forming a yellow vapor, and may be distilled. If melted sulphur, heated above 200° C. (392° F.), is suddenly cooled by being poured out into water, it becomes a reddish-brown plastic mass, with alteration of properties, called *soft sulphur* (*viscid sulphur*), which constitutes another allotropic variety, and is employed in taking impressions of medals, etc. This form of sulphur resumes the hard state, but not its original color, after the lapse of a few days, or suddenly if heated to 100° C. (212° F.). Sulphur is insoluble in water, but soluble in alkaline solutions, petroleum, rectified coal naphtha, the fixed oils, oil of turpentine and other volatile oils, alcohol and ether, chloroform, and carbon disulphide. One of its best solvents is carbon disulphide, from solution in which it crystallizes generally in rhombic octahedra, forms belonging to a different system from the monoclinic prisms obtained by crystallizing melted sulphur by cooling. Hence sulphur is said to be dimorphous. M. Eugène Pelouze has observed that the oils obtained by distilling the tar from gas-works dissolve most sulphur at a temperature near their boiling point, and, if a saturated solution at this heat were to be allowed to cool, it would deposit sulphur in a crystalline form; and M. C. Wiedmann has suggested the application of this property to extraction of sulphur from native sulphur earths and ores, and from the residue of coal-gas works. (*A. J. P.*, June, 1871, p. 267.)

The allotropic states of sulphur have been studied chiefly by Brodie, Magnus and Weber, and Berthelot. These states are induced, for the most part, by heat, and are distinguished by the crystalline form of the sulphur, and by its solubility or non-solubility in carbon disulphide. *Insoluble sulphur* is the name given to that part of the soft sulphur which is left undissolved by the disulphide, amounting to between one-third and nearly one-half of the former. Mr. Brodie was unable to determine the melting point of this sulphur, but found it considerably above 120° C. (248° F.), or the melting point of prismatic sulphur. Flowers of sulphur contain about one-third of their weight of insoluble sulphur.

According to M. Marès, sulphur mixed with calcium carbonate, in the presence of the organic matters of the soil, is converted at first into hydrogen sulphide, then, under the influence of air and porous bodies, into sulphuric acid, finally into calcium sulphate; but Prof. Egidio Pollacer, on the contrary, thinks that sulphur in contact with calcium carbonate passes very readily into sulphuric acid, and then to calcium sulphate, independently of organic matters, and without being preliminarily changed into hydrogen sulphide; and this opinion he supports by several experiments. (*Journ. de Pharm.*, Oct. 1874, p. 330.)

Sulphur takes fire at about the temperature of 148·8° C. (300° F.), and burns with a blue flame, combining with the oxygen of the air, and giving rise to sulphurous oxide, SO_2. The combinations of sulphur are numerous, and are among the most powerful chemical agents. It forms with oxygen two oxides, *sulphurous* oxide (sulphur dioxide), SO_2, and *sulphuric* oxide (sulphur trioxide), SO_3. These oxides, by their union with water, form *sulphurous acid*, H_2SO_3, and *sulphuric acid*, H_2SO_4. There are also known *hyposulphurous acid*, H_2SO_2, the corresponding oxide of which is not known, and in combination *thiosulphuric acid* (frequently spoken of as hyposulphurous acid), $H_2S_2O_3$, and a series of acids, $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$, and $H_2S_5O_6$, called the *thionic series*. It forms with hydrogen, hydrogen sulphide (*hydrosulphuric acid* or *sulphuretted hydrogen*); and with the metals, various *sulphides*.* Some of the sulphides are analogous to acids, others to bases; and these different sulphides, by combining with one another, form compounds which, from their analogy to salts, are called by Berzelius *sulphosalts*.

Sulphur, when obtained by roasting the native sulphide, sometimes contains arsenic, and is thereby rendered poisonous. Sicilian sulphur, being volcanic, is not subject to this impurity. The common English roll sulphur is sometimes made from iron pyrites, and is then apt to contain orpiment (*arsenic tersulphide*). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic acid; and the nitric solution, diluted with water, neutralized with sodium carbonate, and acidulated with hydrochloric acid, will give a yellow precipitate of arsenic pentasulphide with a stream of hydrogen sulphide. A precipitate may be more readily obtained from the nitric solution if, after neutralization, sulphurous acid be added, which will convert the arsenic acid into the arsenous. This is more easily decomposed by the hydrogen sulphide; but the precipitate obtained will now be the tersulphide. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble without residue in oil of turpentine. According to Dr. Playfair, a solution of sodium nitro-prusside is a delicate test for the alkaline sulphides, producing with them a violet tint. The late Prof. Bailey, of West Point, employed the same test for detecting sulphur in any compound. The substance suspected to contain it is fused with sodium carbonate, with the addition of carbonaceous matter if necessary. If sulphur be present it will be converted into sodium sulphide; and upon the addition of a small portion of the fused mass to a drop of the nitro-prusside the characteristic violet tint will be produced.

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*), is "a fine yellow powder, having a slight characteristic odor, and a faintly acid taste. Insoluble in water; slightly soluble in absolute alcohol; more readily soluble in benzin, benzol, oil of turpentine, and many other oils; also in ether, in chloroform, and in boiling, aqueous solutions of alkaline hydrates.

* *Ferri Sulphidum*, FeS; 88. *Ferrous Sulphide.* "Protosulphide of Iron, prepared by melting together Iron, in small pieces, and Sublimed Sulphur." *U. S.* 1870.

This was introduced into the U. S. Pharmacopœia of 1870 as the material from which hydrogen sulphide may be obtained, which, though not official, is in constant use as a reagent, and is often employed with great advantage in processes for isolating the active principles of medicinal substances. Ferrous sulphide is best prepared by bringing iron and sulphur into contact at a red or white heat. The following are the processes of the late Dublin and Edinburgh Pharmacopœias.

"Take of rods of Iron, of the size employed in the manufacture of nails, *any convenient number*. Having raised them to a strong red or white heat, apply them in succession by their heated extremities to sticks of Sulphur, operating so that the melted Sulphide, as it is formed, may drop into a stone cistern filled with water, and be thus protected from oxidation. The water being poured off, let the product be separated from the Sulphur with which it is mixed, and, when dried, let it be enclosed in a well-stopped bottle." *Dub.*

"An inferior sort, good enough, however, for many purposes, is obtained by heating one part of Sublimed Sulphur and three of Iron Filings, in a crucible, in a common fire till the mixture begins to glow, and then removing the crucible, and covering it until the action, which at first increases considerably, shall come to an end." *Ed.*

Iron and sulphur form a number of sulphides, such as ferrous sulphide, FeS, ferric disulphide, FeS_2 (this occurs in nature as *common* or *cubic pyrites*), and ferric sesquisulphide, Fe_2S_3, which, while not found free in nature, occurs in magnetic pyrites, the formula of which is Fe_7S_8 or $5FeS + Fe_2S_3$. When the sulphide is obtained by the application of solid sulphur to white-hot iron, the product corresponds with magnetic pyrites; but when procured by heating flowers of sulphur with an excess of iron filings, as directed in the above Edinburgh process, a protosulphide is formed mixed with metallic iron. When sulphur is applied to white-hot iron over water, the metal appears to become hotter, burns with scintillations in the vapor of the sulphur, and changes instantly to sulphide, which, being comparatively fusible, melts into globules; these drop into the water, which serves to extinguish them.

Properties. Ferrous sulphide has a yellowish color and the metallic lustre. When obtained over water it is in the form of brownish-yellow globules having a somewhat crystalline texture. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or hydrochloric acid without leaving a residue of sulphur, and with the production of hydrogen sulphide free from admixture of hydrogen. As prepared, however, by the usual processes, it is not entirely soluble in dilute sulphuric acid, a portion of uncombined sulphur being left. The fused globules have the composition $5FeS + FeS_2$, or, according to some, $5FeS + Fe_2S_3$. This sulphide is employed solely as a pharmaceutical agent for the production of hydrosulphuric acid. It yields this gas by reaction with diluted sulphuric acid, $FeS + H_2SO_4 = H_2S + Fe.SO_4$. Sulphuretted hydrogen is a colorless gas, with a smell like that of putrid eggs. Its sp. gr. is 1·1782. It saturates bases, with which it forms salts called sulphides.

Carbon disulphide promptly dissolves a portion of it, but leaves a residue of amorphous sulphur, which may be dissolved by a boiling solution of an alkaline hydrate. At 115° C. (239° F.) it melts, and at a higher temperature it volatilizes, or, if air be admitted, burns to sulphur dioxide, characterized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate test-solution held in the gas. When agitated with water, the latter gives an acid reaction with litmus paper. The amount of residue left after volatilizing or burning a weighed portion of it should not exceed 0·5 per cent." *U. S.* "A slightly gritty powder of a bright greenish-yellow color, without taste and without odor. Under the microscope it is seen to consist of almost opaque irregular particles without any admixture of crystalline matter. It burns with a blue flame, forming sulphurous anhydride; and is entirely volatilized by heat. It should not have any action upon *litmus*. *Solution of ammonia*, agitated with it, and filtered, does not on evaporation leave any residue (absence of arsenium sulphide)." *Br.* It is always contaminated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. Accordingly, it always reddens litmus, and, if the acid is present in considerable quantity, sometimes cakes. It may be freed from acidity by careful washing with diluted ammonia water. (See *Sulphur Lotum.*)

Medical Properties and Uses. Sulphur is laxative, diaphoretic, and resolvent. It is supposed to be rendered soluble by the soda of the bile. M. Mialhe teaches that it is carried into the circulation by the fatty matters in the alimentary canal which dissolve it. (*Med. Times and Gaz.*, June, 1868, p. 642.) It evidently passes off by the pores of the skin, as is shown by the fact that silver worn in the pockets of patients under a course of it becomes blackened with a coating of sulphide. The stools which it occasions are usually semi-solid, and it is gentle in its operation, unless it contain a good deal of acid, when it may cause griping: the liability of the sublimed sulphur to contain acid renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used are *hemorrhoids*, *atonic gout*, *chronic rheumatism*, *chronic catarrh*, and *asthma*. It has also been given as an antiperiodic, being considered particularly applicable to cases in which the apyrexia is incomplete. Applied locally, it is a specific in *scabies*. It is sometimes applied as an air-bath, in the form of sulphurous acid gas, the head being protected from its effects.* It has been used to a considerable extent in *diphtheria*, the flowers being blown by means of a tube, or a little cone of paper like a lamp-lighter, upon the fauces from four to six times a day. The external use of sulphur is strongly recommended by Dr. O'Connor, of London, in *sciatica* and *chronic articular rheumatism*. The limb affected is covered with sulphur, and bandaged with new flannel, over which sheets of wadding are wrapped. The dressing should not be taken off for several days, as its earlier removal would interfere with the absorption of the sulphur, on which its curative effect depends. (*Lancet*, Am. ed., June, 1857, p. 507.) The dose of sulphur is from one to three drachms (3·9–11·65 Gm.), mixed with syrup or molasses, or taken in milk. It is often combined with potassium bitartrate, or with magnesia.

According to M. Hannon, of Brussels, *soft sulphur*, recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The dose of soft sulphur is from twenty to fifty grains (1·3–3·25 Gm.), given in the form of pill. It has also been successfully employed for filling the hollows of *carious teeth*. (*P. J. Tr.*, xvii. 330.)

Much sulphur is consumed in the arts, principally in the manufacture of gunpowder and of sulphuric acid.

SUMBUL. U. S. (Br.) Sumbul.

(SŬM'BŬL.)

"The root of Ferula Sumbul (Kauffmann), Hooker filius (nat. ord. Umbelliferæ)." *U. S.*
"The dried transverse slices of the root of Ferula Sumbul, Hook." *Br.*

Sumbul Radix, *Br.*; **Racine de Sumbul**, *Fr.*; **Sumbulwurzel, Moschuswurzel**, *G.*

Under the name of *sumbul* or *jatamansi*, a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It was the root of a then unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Bootan, Bucharia, etc. The root is

* *Sulphur candles* are now furnished by manufacturers, and are made by inserting wicks into melted sulphur contained in a can: as the sulphur cools, the wicks retain an upright position, and to obtain the effects of sulphurous acid gas it suffices to light the wicks and permit the fumes to come in contact with moist air. They are used for disinfecting apartments, etc.

taken northward to Russia, and reaches the rest of Europe through St. Petersburg. The physicians of Moscow and St. Petersburg were the first to employ it on the continent of Europe. Dr. Granville first introduced it to the notice of the profession in Great Britain and in this country. It has also been imported into England from India, whither it was brought from a great distance.

Ferula Sumbul. Hooker fil. *Bot. Mag.* (1875) t. 6196.—*Euryangium Sumbul.* Kauffmann. *Nouv. Mém. Soc. Imp. Nat. de Moscow* (1871), xiii. t. 24, 25. The plant which yields sumbul was first discovered by the Russian Fedschenko in 1869, growing at an elevation of 3000 feet in the mountains which separate Russian Turkestan from Bucharia. In 1871 it was described by Kauffmann, who erected a new genus on characters dependent upon the enormous size of the vittæ in the immature fruit. The plant has been cultivated in the Moscow botanical gardens, and, less successfully, at Kew; and it has been found that the vittæ almost disappear in ripening, and do not afford a good generic character. The plant is described as an enormous umbellifer, reaching a height of eight feet, and having a solid, cylindrical, slender stem, which in the upper part gives origin to about twelve slender divaricate branches. The root-leaves are two and a half feet long, with short, channelled, broadly dilated, completely clasping petioles. They are triangular in outline, tripinnate, with the alternate divisions fine. The stem-leaves rapidly decrease in size until they become above mere sheathing bracts. The flowers are polygamous, the fruit from three-eighths to one-half inch long by one-quarter inch wide; the mericarps oblong-oval, dorsally much compressed, thin, with three faint, thread-like, dorsal ridges; no dorsal vittæ, and commissural ones collapsed. The fact that the sumbul of commerce of late years is inferior in quality to that imported twenty-five years ago has led Holmes to believe that the sumbul root of the present day is probably derived from a different plant. J. E. Aitchison states (*Trans. Linn. Soc.*, ser. 2, *Bot.*, 69) that the root of *Ferula suaveolens*, which has only a faint musky odor, is one of the kinds exported from Persia to Bombay by the Persian Gulf. For an account of the cultivation of sumbul in England, see article by Holmes in *P. J. Tr.*, 1897, April 24.

Properties. Sumbul is officially described as "in transverse segments, varying in diameter from about 2 to 7 Cm., and in length from 15 to 30 Mm.; light, spongy, annulate or longitudinally wrinkled; bark thin, brown, more or less bristly fibrous; the interior whitish, with numerous brownish-yellow resin-dots and irregular, easily separated fibres; odor strong, musk-like; taste bitter and balsamic." *U. S.* The freshly-cut surface of a transverse section presents, within the epidermis, an exterior white and spotted layer, and an inner yellow substance which forms the greater part of the root. Examined by means of a microscope, it exhibits translucent points. Sumbul has a strong odor, much resembling that of musk, which it retains when long kept; and hence the name of *musk-root* sometimes attached to it. The taste, at first feebly sweetish, becomes after a time bitterish and balsamic, but not disagreeable; and a strong aroma is developed under mastication, diffusing itself with a sensation of warmth through the mouth and throat and rendering the breath fragrant. This effect, however, is much diminished by time. That which was formerly brought from India differs somewhat from the Russian, being of closer texture, more dense and firm, and of a reddish tint. (*A. J. P.*, xxiv. 174.) The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether, wax, gum, starch, a bitter substance soluble in water and alcohol, and an acid which was named *sumbulic acid*, but which Riecker and Reinsch showed to be *angelic acid*, $C_5H_8O_2$, accompanied by a little valerianic acid, $C_5H_{10}O_2$. Solution of potash is said to convert the resin into the potassium salt of an acid called *sumbulamic*, but which has not been sufficiently investigated. The musk-like odor seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil, of which ½ of 1 per cent. is yielded by distillation, has a taste like that of peppermint. On dry distillation it yields a bluish oil which contains *umbelliferone*. Philip H. Utech (*A. J. P.*, 1893, p. 465) has extracted and purified the resin soluble in alcohol. He obtained it as a soft, whitish, translucent resin which, on drying at 110° C., yielded a clear, transparent, amber-colored product having a bitter taste and the aromatic odor of the root. It constituted 6·1 per cent. of the drug. J. H. Hahn (*Proc. Penna. Ph. Assoc.*, 1896, 75) found 17·25 per cent. of fixed oil in sumbul.

Medical Properties. Sumbul is a nervous stimulant, belonging to the class of antispasmodics, and was originally used by the Russian physicians as such, and also in asthenic cases of *dysentery* and *diarrhœa*. It has been employed to a considerable extent in this country in *amenorrhœa*, *hysteria*, *chlorosis*, and other allied diseases of the female sex, as an

adjuvant to other remedies. The best preparations for use are the tincture and the fluid and solid extracts. There has been no great precision as to dose, but from one-half drachm to two drachms (1·95–7·8 Gm.) of the root or its equivalent may be given at a time.

Dr. Murawieff, of Russia, prepares the resin, which he considers to be the active principle, by macerating the root first in water, and then in a solution of sodium carbonate, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it. The resin thus obtained is whitish, translucent, softening between the fingers, combustible without residue, of an acid taste, and an aromatic smell, like that of the root. Dr. Murawieff gives it in the dose of a grain or two (0·065 or 0·13 Gm.), in the form of pill, three or four times a day, with or without opium, and has found it useful in *chronic bronchitis* and *pneumonia slow of resolution*, in the *moist asthma* of old, *anæmic*, and *scorbutic patients*, in *atonic dysentery*, *leucorrhœa*, *hypochondriasis*, and *hysteria*. (*Dubl. Quart. Journ.*, Feb. 1855, p. 252.) Prof. Procter has published a formula for a fluid extract, of which the dose is from fifteen minims to a fluidrachm (0·9–3·75 C.c.). (*A. J. P.*, xxvii. 233.) Half an ounce of a tincture produced narcotic symptoms, such as confusion of the head, a tendency to snore, even when awake, feelings of tingling, etc., with a strong odor of the medicine from the breath and skin, which continued for a day or two and gradually passed off. (*N. R.*, Oct. 1874, p. 309.)

SUPPOSITORIA. U. S. Suppositories.

(SŪP-PŎŞ-Ị-TŌ′RỊ-Ą.)

Suppositoires, *Fr.*; Stuhlzäpfchen, *G.*

Suppositories are solid bodies usually intended to be introduced into the rectum with a view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighboring parts or on the system at large. Suppositories are also made for vaginal or urethral administration. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical, the last being preferable when the bulk is small, or they may be in the shape of the modified cone with a tapering base, as recommended by H. S. Wellcome. (*Proc. A. P. A.*, 1893, p. 103.) They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle; with a view to the specific effects of medicines it should be considerably smaller, as in this case it is important that the medicines should be retained and the irritative influence of distention avoided. Soap is not unfrequently employed in this way as a laxative. A piece of solidified molasses (molasses candy) is sometimes preferred. To increase the purgative effect, and at the same time act on the uterine function, aloes may be added to the soap. Mr. A. B. Taylor, of Philadelphia, in 1852 called attention to cacao butter as the best base for suppositories, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, etc., that could be employed. (*A. J. P.*, 1852, p. 211.) Experience has proved the correctness of his views. It has been thought necessary to use wax, spermaceti, or some other substance having a comparatively high fusing point, in order to render the suppository sufficiently firm. Continued experience has, however, demonstrated that, except in the warmest weather, or in the case of camphor, carbolic acid, the essential oils, and similar medicinal substances, even the commercial cacao butter will suffice. It is stated that cacao butter is usually adulterated with some other fat which melts at a low temperature, and that if a pure article can be obtained any substance to increase its hardness is never required. When such a material is employed, wax is usually selected, although cetaceum is preferable. If not more than 10 per cent. of the spermaceti is added, the value of the suppository is not very materially affected, although it melts more slowly, and consequently requires a longer time to act, than when the butter of cacao is used alone. Suppositories containing a considerable percentage of wax melt so slowly in the rectum as to be comparatively useless, or they may fail altogether to soften down, and be finally passed from the anus unchanged. A very good method of mixing the oil of theobroma with the hardening material is by grating with an ordinary tin grater, such as used in kitchens, and mixing the coarse powders before melting; and Mr. W. G. Ewing has proposed

rubbing the powders and the medicinal substance in a mortar together, dividing the plastic mass, and shaping it with the fingers. It is better to shape them with a spatula, and roll them upon a pill tile with a little lycopodium. This plan, although having its advantages, is, however, not equal to the official one of melting the ingredients and running them into moulds. Extemporaneous moulds, made by rolling paper into cones about an inch long, may be used, but are much less convenient than permanent metallic moulds. The tendency of the hardened suppositories to adhere to the moulds may be overcome more or less perfectly by dusting the moulds with lycopodium powder, or greasing them well with olive oil; but it is far better to rely upon the natural contraction of the mass, caused by thoroughly cooling the moulds. Mr. Wm. B. Addington (*A. J. P.*, 1873, p. 257) advises lining the moulds with tin-foil. The difficulty may also be met by the use of moulds that open lengthwise, which are now used almost exclusively in preference to individual moulds, and Mr. Chas. E. Dwight commends very highly the substitution of plaster-of-Paris moulds* for the metallic ones commonly employed. The mould must be very cold, so as to chill the melted liquid at once and prevent any separation of its ingredients by gravity. It has been proposed to condense the powdered ingredients of suppositories in a cold mould. (*A. J. P.*, 1875, p. 79.) It has also been recommended to form the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards enclosed by a little of the cacao butter. But, as one of the objects of the excipient is an equable diffusion of the medicine, to prevent irritation, this method would be inapplicable to substances in any degree locally irritant.

The weight—*i.e.*, the size—of suppositories should vary according to the purposes for which they are employed. When they are to be used for infants and children, they should weigh from five to ten grains. The Br. Pharm., in conformity with the recommendation of Mr. H. B. Brady (*P. J. Tr.*, 1866, p. 544, 1868, p. 321, and 1871, pp. 193, 488, 563),† adopts the weight of fifteen grains. Experience has shown this to be the most useful size, and the U. S. P. 1880 adopted it. The official directions of the U. S. Pharmacopœia of 1890 are as follows. "Take of The Medicinal Ingredient, *the prescribed quantity*, Oil of Theobroma, *a sufficient quantity*. Having weighed out the medicinal ingredient or ingredients, and the quantity of Oil of Theobroma required according to the kind of Suppository to be prepared (see below), mix the medicinal portion (previously brought to a proper consistence, if necessary) with a small quantity of the Oil of Theobroma, by rubbing them together, and add the mixture to the remainder of the Oil of Theobroma, previously melted and cooled to the temperature of 35° C. (95° F.). Then mix thoroughly, without applying more heat, and immediately pour the mixture into suitable moulds. The moulds must be kept cold by being placed on ice, or by immersion in ice-cold water before the melted mass is poured in. In the absence of suitable moulds, Suppositories may be formed by allowing the mixture, prepared as above, to cool, care being taken to keep the ingredients well mixed, and dividing the mass into parts, of a definite weight each, of the proper shape. Unless otherwise specified, Suppositories should have the following weights and shapes, corresponding to their several uses. *Rectal Suppositories* should be cone-shaped, and of a weight of about *one gramme* [or 15½ grains]. *Urethral Suppositories* should be pencil-shaped, and of a weight of about *one gramme* [or 15½ grains]. *Vaginal Suppositories* should be globular, and of a weight of about *three grammes* [or 46 grains]." *U. S.* The Pharmacopœia of 1890 gives no detailed formulæ for suppositories, except in one case, *Suppositoria Glycerini*. Opium, or some one of its preparations, is very advantageously administered in the form of a suppository, in cases of irritation of the rectum, urinary passages, or genital apparatus. The other narcotics may be used in the same way, and indeed almost any other medicine, in reference to its effects on the system, provided the quantity be

* Mr. Dwight makes these moulds in the following manner. Into a pasteboard box, about six inches long and two wide, pour liquid plaster about the consistence of thick cream until half full. Having prepared six well-moulded suppositories of wax, immerse them in the soft plaster half their diameters, with their large end close to the edge of the box, in a row, and at a uniform distance. When the plaster has set, gently remove the wax, and with a knife smooth off the surface and trim the edges of each mould sharp, and between each depression made by the wax suppository dig a small cavity about the size and shape of a small pen cut through the centre. When the face has become hard, grease it with linseed oil or lard, replace the wax suppositories, and raise the edges of the box by wrapping heavy paper around it, which will extend about another inch above the surface of the face; pour a portion of the plaster, equal to the first, gently over the greased surface until it is about one inch deep. When hard, separate the parts carefully, trim the edges, and boil for an hour in linseed oil, which will prevent the adhesion of the substance to be moulded. To be substantial, the plaster must be mixed thin and well stirred.

† The papers of Mr. Brady upon the subject of suppositories may be consulted with advantage; also a series of articles by several other authors in *A. J. P.*, 1871.

not too large and the effects not too pronounced. Tannic acid or other local remedies may also be very appropriately employed in this way in cases of *prolapsus* or other affections of the rectum or anus. The dose may in general be one and a half times that of the medicine given by the mouth.*

The inventive genius of pharmacists has been industriously applied to the construction of suppository moulds, and there are now many varieties: the principle is much the same in all, however, but for convenience they may be classed as follows. 1. Individual moulds: these were among the first to be used. Half a dozen conical, hard-metal moulds are retained in an upright position in a tray containing ice-water, or made of paper, tin-foil, etc. (See *A. J. P.*, 1861, p. 5; 1863, p. 228; 1867, p. 121; 1868, p. 52; 1870, pp. 296, 392.) 2. Moulds which consist of two solid pieces of metal, hinged or temporarily joined, so that when the suppository is thoroughly cooled the parts may be separated and the suppository dropped out. (See *A. J. P.*, 1871, pp. 488, 563; 1874, pp. 192, 246; 1875, pp. 98, 202; 1877, p. 569; 1879, pp. 184, 277; and *Proc. A. P. A.*, 1893, p. 103.) 3. Moulds designed to be used through compression, more or less powerful. (*N. R.*, June, 1879, Jan. and March, 1880; also *Proc. A. P. A.*, 1897, p. 442.)

SUPPOSITORIA ACIDI CARBOLICI. Br. Phenol Suppositories.

(SŪP-PŎŞ-Ĭ-TŌ′RĬ-Ą ĂÇ′Ĭ-DĪ CĂR-BŎL′Ĭ-CĪ.)

"Phenol, 12 *grains* or 0.8 gramme; White Beeswax, 24 *grains* or 1·6 grammes; Oil of Theobroma, melted, *a sufficient quantity* to form, with the Phenol and Beeswax, a mixture which will fill twelve suitable moulds, each capable of holding *fifteen to sixteen grains* or about one gramme of Oil of Theobroma. Dissolve the Phenol in the Oil of Theobroma and Beeswax previously melted together at a low temperature, and pour the mixture into the moulds; or let the mixture cool and then divide it into twelve equal parts of a conical or other convenient form for a suppository. Each of these Suppositories contains 1 *grain* or 0·067 gramme of Phenol." *Br.*

These suppositories are intended to furnish a means of administering carbolic acid per rectum; the wax is needed to offset the tendency to liquefy.

SUPPOSITORIA ACIDI TANNICI. Br. Tannic Acid Suppositories.

(SŪP-PŎŞ-Ĭ-TŌ′RĬ-Ą ĂÇ′Ĭ-DĪ TĂN′NĬ-CĪ.)

Suppositoires de Tannin, *Fr.*; Tannin-Stuhlzäpfchen, *G.*

"Tannic Acid, 36 *grains* or 2·4 grammes; Oil of Theobroma, *a sufficient quantity* to form with the Tannic Acid a mixture which will fill twelve suitable moulds, each capable of holding *fifteen to sixteen grains* or about one gramme of Oil of Theobroma. Melt the Oil of Theobroma; triturate the Tannic Acid intimately with a little of the Oil, and add to the remainder; stir well; as the mixture begins to thicken pour it into the moulds; or let the mixture cool and then divide it into twelve equal parts of a conical or other convenient form for a suppository. Each of these Suppositories contains 3 *grains* or 0·2 gramme of Tannic Acid." *Br.*

As it is hardly conceivable that a rectal dose of less than five grains should be wanted for the adult, the U. S. preparation of 1870 was of the latter strength (*i.e.*, five grains). The benzoated lard formerly added by the British authorities with a view of preventing rancidity has been omitted. The remedy is especially applicable to cases of *piles* and *prolapsus of the rectum.*

* *Medicated Pessaries*, which were recommended by Sir J. Y. Simpson, of Edinburgh, so closely resemble suppositories, so far as pharmacy is concerned, as to justify a mention of them in this place. All that has been said of the materials out of which suppositories are made, and the mode of preparing them, is equally applicable to medicated pessaries. The latter, however, are considerably larger, generally weighing one or two drachms. They differ also from suppositories in the purposes to which they are applied, being used for local effect, in allaying pain, checking discharge, acting as alterative to contiguous parts, etc. For important pharmaceutical details, see an article in *A. J. P.*, 1868, p. 223.

Urethral and Vaginal Suppositories. Medicated Bougies. These articles, which are exceedingly useful for the purpose of exerting a local action upon the urethra or the neck of the bladder in cases of inflammation, pain, or spasm, may be made in the same manner as ordinary suppositories, except in regard to size. The vaginal suppository should be about two to two and a half inches long, and three-quarters of an inch in diameter at the base. Urethral suppositories should be cylindrical, with a conical point, and about one-fourth of an inch in diameter; their length should vary according to circumstances. They should never contain wax or other substance which does not melt readily and certainly at the temperature of the body, and which might, by a possible mishap, become the nucleus of a calculus. When it is desired to reach any considerable length of the urethra, the requisite toughness may be obtained, as suggested by Mr. Jos. L. Lemberger (*A. J. P.*, 1872, p. 166), by using a mould like an old-fashioned candle-mould, with a candle-wick running through and projecting some distance from it. When a suppository so made is used, of course the free end of the wick should be secured with sticking-plaster or a drop of collodion externally, and after the requisite period of contact the whole be pulled out. These are now largely made from gelatin, water, and a little glycerin. (See C. L. Mitchell's paper, *A. J. P.*, 1878, 108; also *P. J. Tr.*, 1895, 537; 1896, 484; and *Proc. A. P. A.*, 1894, 614.) For *Agar-Agar Suppositories*, see *A. J. P.*, 1895, 599; also *Proc. A. P. A.*, 1897, 443.

SUPPOSITORIA BELLADONNÆ. Br. Belladonna Suppositories.

(SŪP-PŎŞ-Ī-TŌ′RĪ-Ą BĔL-LĄ-DŎN′NÆ.)

"Alcoholic Extract of Belladonna, 18 *grains* or 1·2 grammes; Oil of Theobroma, *a sufficient quantity* for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains, approximately, $\frac{1}{60}$ *grain* or 0·001 gramme of the alkaloids of Belladonna Root." *Br.*

SUPPOSITORIA GLYCERINI. U. S., Br. Suppositories of Glycerin.

(SŪP-PŎŞ-Ī-TŌ′RĪ-Ą GLĬÇ-Ē-RĪ′NĪ.)

"Glycerin, *sixty grammes* [or 1 fluidounce, 299 minims]; Sodium Carbonate, *three grammes* [or 46 grains]; Stearic Acid, *five grammes* [or 77 grains]; To make *ten rectal suppositories.* Dissolve the Sodium Carbonate in the Glycerin in a capsule on a water-bath; then add the Stearic Acid, and heat carefully until this is dissolved, and the escape of carbonic acid gas has ceased. Then pour the melted mass into suitable moulds, remove the suppositories when they are cold, and wrap each in tin-foil. The suppositories should be freshly prepared when required." *U. S.*

"Gelatin, cut small, ½ *ounce* (Imperial) or 14·2 grammes; Glycerin, 2½ *ounces* (Imp.) or 71·0 grammes; Distilled Water, *a sufficient quantity.* Place the Gelatin in a weighed evaporating dish with sufficient Distilled Water to cover it; let it stand for two minutes; pour off the excess of Distilled Water; set aside until the Gelatin is quite soft; add the Glycerin; dissolve on a water-bath; evaporate until the mixture weighs *fifteen hundred and sixty-three grains* or one hundred and two grammes. Pour the product into suppository moulds having capacities equal to *thirty, sixty, or one hundred and twenty grains* or two, four, or eight grammes of the Suppository, or of such other capacities as may be required. Each of these Suppositories contains 70 per cent. of Glycerin." *Br.*

This was a new official suppository of the U. S. P. 1890. Glycerin suppositories have come into extensive use, the object being to introduce glycerin into the rectum with a minimum amount of other ingredients. Stearic acid was selected on account of its forming with sodium carbonate the hardest soap attainable, thus permitting the introduction of a suppository containing at least 90 per cent. of glycerin, some water from the sodium carbonate and glycerin being evaporated during the manipulation. This process was perfected by J. P. Remington. (See *Practice of Pharmacy*, 2d ed., 1213.) The British method, on account of the use of gelatin, permits the presence of only 70 per cent. of glycerin, the suppository not being firm enough for convenient application, and, in addition, the method of hydrating the gelatin is faulty. (*Chem. and Drug.*, 1898, 831.) Instead of wrapping the suppositories in tin-foil, it will be found more satisfactory to insert each one in a small glass tube of the proper size, corked at both ends. Some protection from the moisture in the air is necessary because of the hygroscopic character of glycerin. (See *P. J. Tr.*, 1893, 63; 1895, 182; *Amer. Drug.*, 1894, 91; *West. Drug.*, 1894, 141; *A. J. P.*, 1895, 599.)

Medical Properties. Glycerin suppositories are very much used to produce fecal discharges in *constipation.* They act by locally irritating the mucous membrane of the rectum, and are often very efficient, though never really purgative. As an occasional remedy they are useful, but their habitual employment is probably injurious to the mucous membrane.

SUPPOSITORIA IODOFORMI. Br. Iodoform Suppositories.

(SŪP-PŎŞ-Ī-TŌ′RĪ-Ą Ī-ŎD-Ǫ-FÖR′MĪ.)

"Iodoform, 36 *grains* or 2·4 grammes; Oil of Theobroma, *a sufficient quantity* for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains 3 *grains* or 0·2 gramme of Iodoform." *Br.*

These suppositories are valuable in cases of rectal inflammation and irritation. It is often possible by their use in *dysentery* to avoid the use of opium to a greater or less extent.

SUPPOSITORIA MORPHINÆ. Br. Morphine Suppositories.

(SŪP-PŎŞ-Ī-TŌ′RĪ-Ą MÖR-PHĪ′NÆ.)

Suppositoires morphinés, *Fr.;* Morphin-Stuhlzäpfchen, *G.*

"Morphine Hydrochloride, 3 *grains* or 0·2 gramme; Oil of Theobroma, *a sufficient quantity* for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains ¼ *grain* or 0·017 gramme of Morphine Hydrochloride." *Br.*

This is an excellent remedy in *strangury*, *tenesmus*, and other cases of *irritation in the lower bowels* and *urinary passages*. It may also be used to control *vomiting*, and to produce the general effects of opium on the system.

SUPPOSITORIA PLUMBI COMPOSITA. Br. Compound Lead Suppositories.

(SŬP-PŎṢ-Ị-TŌ′RĮ-Ą PLŬM′BĪ CǪM-PŎṢ′Ị-TĄ.)

Suppositoires de Plomb opiacés, *Fr.;* Stuhlzäpfchen von Opium und Bleizucker, *G.*

"Lead Acetate, in powder, 36 *grains* or 2·4 grammes; Opium, in powder, 12 *grains* or 0·8 gramme; Oil of Theobroma, *a sufficient quantity* for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains 3 *grains* or 0·2 gramme of Lead Acetate and 1 *grain* or 0·067 gramme of Opium." *Br.*

An excellent remedy in some cases of *diarrhœa*, *dysenteric irritation of the rectum*, *piles*, and *hemorrhage*.

SYRUPI. Syrups.

(SỊ-RŬ′PĪ.)

Sirops, *Fr.;* Syrupe, *G.*

Syrups are concentrated solutions of sugar in aqueous fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup;* when made with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its special designation from the substance or substances added.

Medicated syrups are usually prepared by incorporating sugar with vegetable infusions, vinegars, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 100° C. (212° F.), it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup and evaporating the alcohol. Another and a better mode of effecting the same object, when aromatic or other volatile substances are concerned, is to mix the tincture with sugar in coarse powder, expose the mixture to a very gentle heat or to the sun till the alcohol has evaporated, and then prepare the syrup from the impregnated sugar by dissolving it in the requisite proportion of water. Since the introduction into use of the process of percolation, or filtration by displacement, it has been applied very advantageously to the preparation of various syrups, especially those made from vegetables of which the active principle is injured or dissipated by decoction. But, unless the operator be at once skilful and careful, there will be danger of imperfectly extracting the active matters, and thus making a feeble preparation. One important practical rule is, when the liquid obtained by percolation requires concentration, to set aside the first portions of filtered liquor, which are usually strongly impregnated, and to subject only the subsequent weaker portions to evaporation. For the mode of properly conducting this process the reader is referred to page 529.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be used, as it saves the necessity of clarification, and makes a clearer and better-flavored syrup than the impure kinds. The U. S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer where an acid, such as lemon-juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the aqueous fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is expedient to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long-continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups

which admit of concentration should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when syrups have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs,—such as the slowness with which the parts of a drop of syrup coalesce, when previously separated by the edge of a blunt instrument, and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools indicates that it has been boiled too much. But these signs are not to be relied on, except by those who have acquired much experience. The proper point of concentration is best ascertained by the use of that variety of Baumé's hydrometer called a *saccharometer*,—an instrument useful to those making syrups upon the large scale. This should stand at 30° in boiling syrup (30½° in hot weather), and at 35° in the syrup when it is cool. Another very accurate, though less ready, method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1·261 ; when cold, of about 1·317. Thomson and Duncan are in error in giving the proper sp. gr. of cold syrup as 1·385. We found that of a specimen of simple syrup, made with two pounds and a half of sugar to a pint of water, as directed in former editions of the U. S. Pharmacopœia, to be 1·326 at 68° F.; but this strength is rather too great for practical convenience in cold weather. In the syrup now official it is only 1·317 at 15° C. (59° F.). A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 105° C. (221° F.). This indication is founded on the fact that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best double-refined sugar, syrups usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a rule, to remove the scum as it rises during the heating process, and to strain the syrup while hot through muslin or flannel. Should syrups at any time lack the due degree of transparency, they may be filtered through paper if a hot-water funnel is used, or, when likely to be injured by this treatment, may be clarified by means of the white of egg or animal charcoal, as mentioned under the head of *Syrupus*. But the active vegetable principles are so apt to be absorbed by the charcoal along with impurities that this agent should be used with caution. The vicious habit of sugar refiners of "blueing" sugars by the use of ultramarine and other coloring agents cannot be too strongly deprecated.

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white deposit, which is a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. Even at ordinary temperatures acids slowly convert common sugar into grape sugar, which, being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups containing too little sugar are subject to the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much deposit a portion in the crystalline state; and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups enclosed while they are still hot in bottles which are not full are apt to ferment, because the watery vapor rising to the surface and there condensing diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass; but if the bottles are filled, or are well shaken, this result is obviated; and the syrups will generally keep better when thus treated. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odor from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of that principle; and, as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling, so as to drive off the alcohol and carbonic acid and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or

one readily changeable by heat, cannot be restored to their original condition. A very convenient method of preparing syrups has come into general use, called the "cold process." For some syrups it is to be preferred to the usual method of heating, and all syrups which contain a volatile principle, or one likely to be injured by heat, are preferably made by *percolation*. Mr. L. Orynski, *Druggists' Circular*, March, 1871, first drew attention to the subject, and R. Hunstock, in *A. J. P.*, Sept. 1875, and Sept. 1878, gave the results of his experience with the process. Into the lower orifice of a percolator he introduces lightly a small piece of sponge; the sugar (granulated) is then poured in, and upon this the water, the apparatus being arranged as is usual in the process of percolation. The percolator may be covered loosely, and the operation will proceed without further attention, the syrup coming through drop by drop. If it should be necessary to use crushed sugar, the percolator must be corked at the lower orifice, and the sugar and water introduced and allowed to macerate until the former has dissolved down to *half its bulk*, when the cork may be removed and the liquid be allowed to drop. If, after the liquid has all passed, there remains a quantity of undissolved sugar in the percolator, after corking the end of the latter, enough percolate may be poured back to dissolve it, afterwards adding sufficient water to bring the whole up to the required measure. Syrups may be made (without heat) *rapidly* by putting the ingredients in a churn and agitating briskly.

To be successful in using the process, care in several particulars must be exercised. 1. The percolator used should be cylindrical or semi-cylindrical, and cone-shaped as it nears the lower orifice. 2. The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. 3. The moistened sponge must be introduced with care. If pressed too tightly in, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (not properly filtered). See also a practical paper on this subject in *A. J. P.*, Jan. 1881, by G. H. Chas. Klie.

"Rock Candy Syrup," the evaporated mother-liquor left after crystallizing sugar in the form of large crystals, called "rock candy," has come largely into use in America. It varies much in quality as made by various manufacturers, and often contains glucose. It should never be used indiscriminately or for making the official syrups, and it should always be carefully tested before being used for any purpose. (See analyses by L. F. Kebler, *A. J. P.*, 1895, 143.)

At best syrups are apt to change, and various measures have been proposed for their preservation; but the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place. Glycerin is often used to aid in the preservation of syrups; in special cases this may be advantageous, but the solvent properties of glycerin must be remembered, and the finished preparation may possess properties (due to the glycerin) which are not found in syrups made without glycerin (see *West. Drug.*, 1898, 444), and which may be injurious in prescriptions.

The following Syrups were dropped from the U. S. Pharmacopœia at the 1890 revision: *Syrupus Ferri Bromidi*, *Syrupus Limonis*, and from the British Pharmacopœia (1898), *Syrupus Ferri Subchloridi*, *Syrupus Mori*, and *Syrupus Papaveris*.

SYRUPUS. U. S., Br. Syrup.

(SY-RŪ'PUS.)

Simple Syrup; Syrupus Sacchari, s. Albus; Sirop de Sucre, Sirop simple, *Fr.*; Weisser Syrup, *G.*

"Sugar, in coarse powder, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Sugar, with the aid of heat, in *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Distilled Water, raise the temperature to the boiling point, strain the liquid, and pass enough Distilled Water through the strainer to make the product, when cold, measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Syrup* may also be prepared in the following manner: Press down into the neck of a percolator or funnel of suitable size a tapering piece of coarse, well-cleaned sponge,* not too tightly, and in such a manner that the whole sponge shall be within the neck of the percolator, its upper end being about half an inch below its commencement. Place the Sugar into the apparatus, make its surface level without shaking or jarring, then carefully pour on *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Distilled Water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Return

* The sponge should be thoroughly moistened with pure water, but any excess should be thoroughly pressed out before inserting it.

the first portion of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Distilled Water, added in portions, so that all the Sugar may be dissolved, and the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Refined Sugar, 5 *pounds* (Imperial) or 1000 grammes; Distilled Water, boiling, *a sufficient quantity*. Add the Refined Sugar to *two pints* (Imp. meas.) or five hundred cubic centimetres of the boiling Distilled Water; heat until dissolved; make the weight of the product *seven pounds and a half* (Imp.) or one thousand five hundred grammes by the addition of boiling Distilled Water. Specific gravity 1·330." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavor, thick, viscid, nearly colorless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any color and peculiar flavor which it may possess may be removed by treating it at the same time with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that when it coagulates it may be rendered by the air which it contains specifically lighter than the syrup, and thus rise to the surface. If not thus treated, it floats, when coagulated in the syrup, or sinks to the bottom. Now, it is obvious that if the syrup and albumen be heated together the latter must be deprived of a portion of the air which it contains before the point of coagulation is attained, and thus become less disposed to rise to the surface. Guibourt, therefore, recommends that it should not be added till the syrup is boiling hot, and should then be poured in from a height, in order to increase the quantity of air entangled in it. M. Magnes-Lahens has found paper pulp to be of the greatest service in the clarification of syrup. He uses a white unsized paper of good quality, reducing it to a paste by agitation in a bottle with a portion of the menstruum to be used, heating it with the syrup during the whole process of solution, and finally filtering through a "swan's-down paper" filter. (*P. J. Tr.*, April, 1872, p. 825.)

From the observations of M. Maumené, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids, the saccharine liquid becoming brown when boiled with potassa. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (*Comptes-Rendus*, xxxix. 914.) Prof. Procter observed a similar change in simple syrup which had been kept in his cabinet for six years. (*A. J. P.*, xxvii. 430.) M. Schaeuffele, having noticed, on one occasion, in the preparation of simple syrup, that the foam exhibited a singular blue color, while a part of the cane sugar was rapidly transformed into the uncrystallizable variety, made investigations as to the cause, and was led to the conclusion that it was the presence of indigo in the loaves of sugar, introduced with the view of giving brilliancy and whiteness; but this conclusion was probably erroneous, as it is well known that *ultramarine*, and not indigo, is used for this purpose. The presence of a blue coloring matter in sugar has frequently been noticed in this country: syrup made from such sugar is not colorless, and in a short time deposits a dark-colored sediment. Colorless "rock candy" forms an excellent source for pure syrup (the broken crystals can be procured cheaply from the manufacturers), and syrup entirely free from impurities is required in making such preparations as syrup of hydriodic acid, ferrous iodide, etc.

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup is practically identical with that formerly official, being a trifle stronger, the sp. gr. being given as 1·317. That of the Br. syrup is 1·330, probably adapted to the climate of Great Britain, which is not so cold in winter as is ours, at least in the Northern and Middle States.

SYRUPUS ACACIÆ. U. S. Syrup of Acacia.

(SY-RŪ'PUS Ą-CĀ'CI-Æ.)

Syrupus Gummosus, *P. G.*; Sirop de Gomme, *Fr.*; Gummisyrup, *G.*

"Mucilage of Acacia, recently prepared, *twenty-five cubic centimeters* [or 406 minims]; Syrup, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims], To make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Mix them. This syrup should be freshly prepared, when required." *U. S.*

We do not think that the direction to make this syrup from mucilage and syrup is an improvement. The greatest objection lies in the fact that mucilage of acacia will sometimes not keep a day in hot weather, and its introduction into syrup without heating will surely induce fermentation, which, when once started, increases with great rapidity in this syrup. We append in a foot-note the process of the U. S. P. 1870, as it is to be preferred.* This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but, unfortunately, the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these two substances. To obviate fermentation, Mr. C. B. Mann commends the use of one fluidounce of glycerin and seven fluidounces of water as the solvent. If the mucilage of acacia be made with chloroform water or a trace of chloroform be added to syrup of acacia, fermentation is measurably retarded.

SYRUPUS ACIDI CITRICI. U. S. Syrup of Citric Acid.

(SY-RŪ'PUS ĂÇ'I-DĪ CĬT'RI-CĪ.)

Sirop d'Acide citrique, *Fr.;* Citronensäuresyrup, *G.*

"Citric Acid, *ten grammes* [or 154 grains]; Water, *ten cubic centimeters* [or 162 minims]; Spirit of Lemon, *ten cubic centimeters* [or 162 minims]; Syrup, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Citric Acid in the Water, and mix the solution with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Syrup. Then add the Spirit of Lemon, and, lastly, enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavor, if the latter be well made. If long kept it is apt to acquire a musty taste, and to deposit grape sugar copiously, in consequence of the action of the acid on the cane sugar. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tartaric acid, on account of its greater cheapness, has not unfrequently been substituted for the citric acid; but the syrup made with it does not keep so well, and is more apt to irritate the stomach.

SYRUPUS ACIDI HYDRIODICI. U. S. Syrup of Hydriodic Acid.

(SY-RŪ'PUS ĂÇ'I-DĪ HĪ-DRI-ŎD'I-CĪ.)

"A syrupy liquid containing about 1 per cent., by weight, of absolute Hydriodic Acid [HI = 127·53], or about 1·3 Gm. in 100 C.c." *U. S.*

"Potassium Iodide, *thirteen grammes* [or 200 grains]; Potassium Hypophosphite, *one gramme* [or 15 grains]; Tartaric Acid, *fourteen grammes* [or 217 grains]; Water, *fifteen cubic centimeters* [or 243 minims]; Diluted Alcohol, Syrup, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the two Potassium salts in the Water, and the Tartaric Acid in *twenty-five cubic centimeters* [or 406 minims] of Diluted Alcohol. Mix the two solutions in a vial, shake it thoroughly, and place it in ice-water for half an hour, occasionally shaking. Then filter the mixture through a small, rapidly-acting, white filter, and carefully wash the vial and filter with Diluted Alcohol, until the filtrate ceases to produce more than a faint cloudiness when a drop or two is allowed to fall into silver nitrate test-solution. Reduce the filtrate, by evaporation in a tared capsule, on a water-bath, to *fifty grammes* [or 1 ounce av., 334 grains], and mix it, when cold, with enough Syrup to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

As an aqueous solution of hydriodic acid is unstable, the iodine being in time always liberated, rendering it irritant and unfit for internal administration (see *Hydriodic Acid*, in PART II.), and as it has been proved that syrup protects the acid efficiently, the 1880 Committee of Revision introduced the Syrup of Hydriodic Acid, with the view of furnishing a preparation which should remain, if carefully preserved, for a long time unchanged. The process for this syrup was changed at the last revision: the National Formulary method, having proved by experience very satisfactory, was incorporated into the U. S. P. 1890. The "Buchanan" method of producing hydriodic acid by the decomposition of potassium iodide with tartaric acid is employed, the resulting acid potassium tartrate being crystallized out by the use of diluted alcohol and a re-

* *Syrupus Acaciæ, U. S.* 1870. "Take of Gum Arabic, in pieces, *two troyounces;* Sugar [refined], in coarse powder, *fourteen troyounces;* Water *eight fluidounces.* Dissolve the Gum Arabic in the Water, without heat, then, having added the Sugar, dissolve it with a gentle heat, and strain." The gum should be carefully selected; and, if its solution contain impurities, it should be strained before the addition of the sugar. On the whole, taking into consideration the great liability to the use of materials not quite pure, it might be advisable, in all cases, to heat momentarily to the boiling point, skim off what may rise to the surface, and then strain.

duced temperature. Decomposition and the discoloration due to the separation of a trace of iodine are obviated by the use of a small quantity of potassium hypophosphite; this in contact with tartaric acid is decomposed, and the trace of hypophosphorous acid generated is sufficient to protect the solution of hydriodic acid from change, the very small quantity of acid potassium tartrate produced at the same time crystallizing out with the rest of the salt in the diluted alcohol. So-called syrup of hydriodic acid is found in the market in which glycerin is the principal constituent. The substitution of glucose for syrup is also practised with a view of preventing discoloration. (*Proc. A. P. A.*, 1897, 221.)

Properties. Syrup of hydriodic acid is officially described as "a transparent, colorless, or not more than pale straw-colored liquid, odorless, and having a sweet and acidulous taste. Specific gravity, about 1·313 at 15° C. (59° F.). If a small portion of the Syrup be mixed with a little starch test-solution, and a few drops of chlorine water then added, the liquid will acquire a deep blue color. Not more than a faint bluish tint should be produced in the Syrup by starch test-solution alone (limit of *free iodine*). The addition of silver nitrate test-solution to a small portion of the Syrup produces a pale yellow precipitate, nearly insoluble in ammonia water. If 32 (31·88) Gm. of the Syrup be exactly neutralized by ammonia water, and then mixed with 2 drops of potassium chromate test-solution, it should require about 25 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red tint (corresponding to about 1 per cent. of absolute Hydriodic Acid)." *U. S.*

Syrup of hydriodic acid has the general therapeutic properties of iodine and the alkaline iodides, and is used by various practitioners to obtain alterative effects in *scrofula* and similar disorders. (See also *Hydriodic Acid, Dilute*, PART II.) As it contains about 1 per cent. by weight of absolute hydriodic acid, for practical purposes a teaspoonful may be said to represent between five- and six-tenths of a grain of iodine and a little over a grain of potassium iodide. It is evident that the doses in which it is usually administered—from twenty to forty minims (1·25–2·5 C.c.)—are absurdly small. It should be well diluted at the time of administration.

SYRUPUS ALLII. U. S. Syrup of Garlic.

(SY-RŪ'PUS ĂL'LI-Ī.)

Sirop d'Ail, *Fr.*; Knoblauchsyrup, *G.*

"Fresh Garlic, sliced and bruised, *two hundred grammes* [or 7 ounces av., 24 grains]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Diluted Acetic Acid, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Macerate the Garlic with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Acetic Acid during four days, and express the liquid, avoiding the use of metallic utensils. Then mix the residue with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] more of Diluted Acetic Acid, and again express. Mix the expressed liquids, and filter. Pour the filtrate upon the Sugar, contained in a suitable vessel, and stir or agitate until the Sugar is dissolved. Lastly, add enough Diluted Acetic Acid to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and mix thoroughly. Keep the Syrup in well-stoppered, completely filled bottles, in a cool place. *Syrup of Garlic* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Diluted Acetic Acid, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This preparation is made upon correct principles, as vinegar is a better solvent of the active matter of garlic than water. The syrup is given in *chronic bronchitis* and the advanced stages of *acute bronchitis* of the lungs, and is particularly beneficial in infantile cases. A teaspoonful (3·75 C.c.) may be given for a dose to a child a year old.

SYRUPUS ALTHÆÆ. U. S. Syrup of Althæa.

(SY-RŪ'PUS ĂL-THÆ'Æ.)

"Althæa, cut into small pieces, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Wash the Althæa with cold Water, then macerate it with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water previously mixed with the Alcohol, during one hour, stir-

ring frequently, and strain without expressing the residue. In the strained liquid dissolve the Sugar by agitation, without heat, add the Glycerin, and enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. Keep the Syrup in well-stoppered, completely filled bottles, in a cool place." *U. S.*

This syrup is almost identical with that of the German Pharmacopœia. The use of alcohol and glycerin in the U. S. 1890 process will probably tend to delay fermentation somewhat. It is an agreeable demulcent, but not superior to syrup of acacia, which it equals in its tendency to ferment. Noffke states that syrup prepared in accordance with the following method will keep well. Ten parts of cut marshmallow root are washed with distilled water, then macerated for three hours in a mixture of five parts of alcohol and two hundred and fifty parts of distilled water, strained without pressure, and the strained liquid made up to four hundred parts with distilled water; three hundred parts of sugar are dissolved in this liquid by the aid of heat, a little paper pulp is added, the syrup is boiled a short time, strained, filtered while hot, and rapidly evaporated to five hundred parts, and at once filled in clean and *dry* vials of suitable size. The syrup so obtained has a light-yellow color. (*Arch. d. Pharm.*, 1886, p. 761.) The dose of the official syrup is from a fluidrachm to half a fluidounce (3·75–15 C.c.).

SYRUPUS AMYGDALÆ. U. S. Syrup of Almond. [Syrup of Orgeat.]

(SY-RŪ'PUS Ă-MĬG'DĂ-LÆ.)

Syrupus Emulsivus; Sirop d'Orgeat (d'Amandes, émulsif), *Fr.;* Mandelsyrup, *G.*

"Sweet Almond, *one hundred and forty grammes* [or 4 ounces av., 411 grains]; Bitter Almond, *forty grammes* [or 1 ounce av., 180 grains]; Sugar, *two hundred grammes* [or 7 ounces av., 24 grains]; Orange Flower Water *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Water, *one hundred and thirty cubic centimeters* [or 4 fluidounces, 190 minims]; Syrup, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Almonds, previously blanched, in a mortar with *one hundred grammes* [or 3 ounces av., 231 grains] of the Sugar and *thirty cubic centimeters* [or 1 fluidounce] of Water to a smooth paste. Mix this well with the Orange Flower Water and *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Syrup, and strain with strong expression. To the residue add *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and express again. In the strained liquid dissolve the remainder of the Sugar, without heat, adding enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Keep the Syrup in well-stoppered, completely filled bottles, in a cool place." *U. S.**

This process corresponds to some extent with that of the French Codex. This is an elegant syrup, much employed in Europe and in this country. It is demulcent, nutritive, and, in consequence of the hydrocyanic acid of the bitter almonds, very slightly sedative. It is said to mask greatly the odor of musk and asafetida, when mixed with them. It may be added to cough mixtures, or used as an agreeable vehicle for administering strong remedies.

SYRUPUS AROMATICUS. Br. Aromatic Syrup.

(SY-RŪ'PUS ĂR-Ō-MĂT'Ĭ-CŬS.)

"Tincture of Orange, 5 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Cinnamon Water, 5 *fl. ounces* (Imp. meas.) or 250 cubic centimetres; Syrup, 10 *fl. ounces* (Imp. meas.) or 500 cubic centimetres. Mix the Tincture of Orange and Cinnamon Water; shake the mixture with a little *powdered talc;* filter; add the Syrup." *Br.*

This is a new preparation of the Br. Ph. 1898, and is practically a simple elixir (see *Elixir Aromaticum*, p. 497): it has been introduced mainly as a vehicle or adjuvant.

SYRUPUS AURANTII. U. S., Br. Syrup of Orange.

(SY-RŪ'PUS ÂU-RĂN'TĬ-Ī—âw-răn'shē-ī.)

Syrup of Orange Peel; Sirop d'Ecorces d'Oranges, *Fr.;* Orangenschalensyrup, *G.*

"Sweet Orange Peel, taken from the fresh fruit, *fifty grammes* [or 1 ounce av., 334 grains]; Precipitated Calcium Phosphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Introduce the Sweet

* *Orgeat Powder.* Dr. Enders, on account of the tendency of syrup of almond to spoil, prepares a powder by making an emulsion of twenty parts of sweet almonds with sufficient water, mixing it with seventy-two parts of sugar, rapidly evaporating with the steam bath and pulverizing the residue, and keeping it in well-corked bottles. To make one hundred parts of the syrup, sixty-eight parts of the powder are dissolved with heat in twenty-four parts of water, and five parts of orange flower water and three parts of bitter almond water are added. (*A. J. P.*, 1874, p. 362.)

Orange Peel (which should be as free as possible from the white, inner layer, and cut into small shreds) into a flask, and add *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of Alcohol. Stopper the flask loosely with a notched cork, apply the heat of a water-bath until the Alcohol boils, and maintain it boiling during five minutes. Then stopper the flask well, and set it aside to cool. Filter off the liquid, and wash the filter and contents with Alcohol until the filtrate measures *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Mix the Precipitated Calcium Phosphate, in a mortar, with *one hundred and fifty grammes* [or 5 ounces av., 127 grains] of Sugar, and add the tincture with constant trituration. To the resulting, pasty mass add *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, triturating constantly, transfer the whole to a filter, and return the first portions of the filtrate, if necessary, until it runs through clear. In the filtrate dissolve the remainder of the Sugar, and add enough Water, through the filter, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Tincture of Orange, 1 *fl. ounce* (Imperial measure) or 30 cubic centimetres; Syrup, 7 *fl. ounces* (Imp. meas.) or 210 cubic centimetres. Mix." *Br.*

The present U. S. formula is an improvement over that of 1870, in which evaporation was resorted to to deprive the tincture of orange peel of alcohol, for, although the temperature was limited to 120° F., even this was sufficient to affect the flavor of the concentrated tincture. In the U. S. P. 1880, by employing maceration and expression with a smaller quantity of alcohol, the use of heat was avoided. The proportion of alcohol directed to extract the oil from the orange peel was necessarily small; indeed, it was almost entirely absorbed by the orange peel, which should be grated. In the U. S. P. 1890 process an attempt has been made to save time by boiling the sweet orange peel in alcohol. In our opinion, a better plan would have been to use the proper proportion of tincture of sweet orange peel (see *Tinctura Aurantii Dulcis*), as this preparation keeps indefinitely, and could easily be strengthened by spontaneous evaporation so as to avoid volatilizing the oil of orange peel. The British preparation, which is a mere mixture of the tincture with syrup, is in all respects inferior. The use of magnesium carbonate was first suggested by Mr. John D. Finley. The syrup has an agreeable flavor, for which it is alone employed. For a process by E. E. Williams, using powdered pumice to disintegrate the orange peel, see *Drug. Circ.*, 1898, 125.

SYRUPUS AURANTII FLORUM. U. S. (Br.) Syrup of Orange Flowers.

(SY-RŪ'PUS ÂU-RĂN'TI-Ī FLŌ'RŬM.)

Syrupus Aurantii Floris, *Br.;* Sirop de Fleurs d'Oranges, *Fr.;* Pomeranzenblüthensyrup, *G.*

"Sugar, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Orange Flower Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Sugar in *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Orange Flower Water by agitation, without heat, add enough Orange Flower Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and mix thoroughly. *Syrup of Orange Flowers* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Orange Flower Water upon the Sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by Orange Flower Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Orange-flower water of commerce, undiluted, 8 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Refined Sugar, 3 *pounds* (Imp.) or 600 grammes; Distilled Water, boiling, *a sufficient quantity*. Add the Refined Sugar to *sixteen fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the boiling Distilled Water; heat until dissolved; add the undiluted Orange-flower water; make the weight of the product *four pounds and a half* (Imp.) or nine hundred grammes by the addition of recently boiled Distilled Water." *Br.*

The second U. S. process, by percolation, will be preferable here. This syrup is used chiefly for flavoring mixtures. The dose is a fluidrachm (3·75 C.c.).

SYRUPUS CALCII LACTOPHOSPHATIS. U. S., Br. Syrup of Calcium Lactophosphate.

(SY-RŪ'PUS CĂL'CI-Ī LĂC-TŌ-PHŎS-PHĀ'TĪS.)

"Precipitated Calcium Carbonate, *twenty-five grammes* [or 386 grains]; Lactic Acid, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Phosphoric Acid, *thirty-six cubic centimeters* [or

1 fluidounce, 104 minims]; Orange Flower Water, *twenty-five cubic centimeters* [or 406 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. To the Lactic Acid mixed with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and contained in a capacious mortar, gradually add the Calcium Carbonate, in portions, until it is dissolved. Then add the Phosphoric Acid, and triturate until the precipitate at first formed is dissolved. Add *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Water, and filter, rinsing the mortar with *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims] of Water, and passing the rinsings through the filter. To the mixed filtrates add the Orange Flower Water, and, having added the Sugar, dissolve it by agitation, without heat, and strain. Lastly, pass enough Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and mix thoroughly." *U. S.*

"Precipitated Calcium Carbonate, 2½ *ounces* (Imperial) or 25 grammes; Concentrated Phosphoric Acid, 4 *fl. ounces* and 262 *minims* (Imp. meas.) or 46 cubic centimetres; Lactic Acid, 6 *fl. ounces* (Imp. meas.) or 60 cubic centimetres; Refined Sugar, 70 *ounces* (Imp.) or 700 grammes; Orange-flower water of commerce, undiluted, 2½ *fl. ounces* (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Calcium Carbonate gradually to the Lactic Acid, diluted with four times its volume of Distilled Water. When solution is complete, add the Concentrated Phosphoric Acid, and triturate until the precipitate which at first forms is dissolved. Dilute with a little Distilled Water; add the undiluted Orange-flower water; filter; dissolve the Refined Sugar in the mixture without the aid of heat; strain; add sufficient Distilled Water to make *five pints* (Imp. meas.) or one thousand cubic centimetres of the syrup." *Br.*

The U. S. P. 1880 syrup was almost identical with the preparation proposed by Mr. William Neergaard. Freshly precipitated calcium phosphate is soluble in lactic acid, and this preparation was such a solution protected from change and rendered more agreeable to the taste by the addition of sugar and orange flower water. As made by this formula it will usually be found to contain a precipitate of a gelatinous character, which gradually forms in the course of a few days or weeks: the means commonly used to prevent this precipitation is the addition of a fluidrachm of hydrochloric acid to a pint of the syrup,—hydrochloric acid being a better solvent for calcium phosphate than is lactic acid. The U. S. P. 1890 process* prepares calcium lactate by dissolving calcium carbonate in lactic acid and subsequently adding phosphoric acid: this should be an improvement, as it simplifies the process. Precipitation can be avoided by the addition of a trace of hydrochloric acid. The process of percolation to dissolve the sugar may be advantageously substituted here for that of agitation. The syrup is sometimes prepared by dissolving two hundred grains of calcium lactophosphate (which is now furnished by the manufacturing chemists) in a pint of syrup flavored with orange flower water, a fluidrachm of hydrochloric acid being added to prevent precipitation. The British syrup is practically identical with the U. S. preparation and was modelled after it. This syrup affords an excellent means of administering calcium phosphate. The dose is from two to four fluidrachms (7·5–15 C.c.), representing from three to six grains of the lime salt.

SYRUPUS CALCIS. U. S. (Br.) Syrup of Lime.

(SY-RŪ'PUS CAL'CIS.)

Liquor Calcis Saccharatus, *Br.*; Saccharated Solution of Lime; Sirop de Chaux, *Fr.*; Kalksyrup, *G.*

"Lime, *sixty-five grammes* [or 2 ounces av., 128 grains]; Sugar, *four hundred grammes* [or 14 ounces av., 48 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Triturate the Lime and Sugar thoroughly in a mortar, so as to form a homogeneous powder; then add the mixture to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of boiling Water, contained in a bright copper or tinned iron vessel, boil for five minutes, constantly stirring, and then strain. Dilute the strained liquid with an equal volume of Water, and filter through white paper. Then evaporate the filtrate, in a tared capsule, to *seven hundred grammes* [or 24 ounces av., 302 grains], allow it to cool, add to it

* *Syrupus Calcii Lactophosphatis—Modified Formula.* Mr. Geo. Thos. Williams has modified the formula of R. Rother and adapted it to the strength of the official preparation. It is as follows: "Take of Precipitated Calcium Carbonate 13 parts; Lactic Acid 33 parts; Phosphoric Acid, U. S. P., 18 parts; Orange Flower Water 80 parts; Sugar in coarse powder 600 parts; Distilled Water sufficient to make 1000 parts. Mix the lactic acid with 136 parts of distilled water, and gradually add the calcium carbonate, warming gently, if necessary. Add the phosphoric acid, previously diluted with 120 parts of distilled water and with the orange-flower water. Filter, and pass enough distilled water through the filter to make the filtrate weigh 400 parts. Lastly, dissolve the sugar by cold percolation or by agitation, and strain."

enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and mix thoroughly. Keep the Syrup in well-stoppered bottles." *U. S.*

"Calcium Hydroxide, 1 *ounce* (Imperial) or 50 grammes; Refined Sugar, in powder, 2 *ounces* (Imp.) or 100 grammes; Distilled Water, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Mix the Calcium Hydroxide with a solution of the Refined Sugar in the Distilled Water. Set aside in a stoppered green glass bottle for a few hours, shaking occasionally; separate the clear Solution with a siphon, avoiding unnecessary exposure to air. Specific gravity 1·055. 10 grammes should require for neutralization 6·3 cubic centimetres of the *volumetric solution of sulphuric acid*. It should not afford any characteristic reaction with the tests for lead. This Solution contains nearly 2 per cent. by weight of Lime, CaO, or about 8 grains in 1 fluid ounce." *Br.*

The British Saccharated Solution of Lime differs from the U. S. Syrup only in containing a smaller proportion of sugar. This new official syrup is almost identical with that proposed by Dr. E. R. Squibb. (See 14th ed. *U. S. D.*, p. 1288; also *Apothecary*, 1894, 18.)

Sugar forms with lime certain definite compounds which may be looked upon as saccharates. According to M. S. Benedikt (*Journ. de Pharm.*, 4e sér., xix. 96), there are at least four of these combinations. Some, if not all, of them are much more soluble than the lime itself, so that in this way a much stronger solution of lime can be obtained than by the instrumentality of water alone. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It was first prepared by M. Béral; and its practical use was originally suggested by Dr. Capitaine, of Paris.*

Medical Properties. Dr. Charles E. Buckingham, of Boston, says in relation to this syrup that it should not be taken either in pill or dissolved in water, as it will occasion nausea or produce a caustic effect. He gives it in milk, and considers thirty drops (1·25 C.c.) every three hours as a sufficient dose. He has never known it to cause alkaline urine. (*Boston Med. and Surg. Journ.*, April 4, 1867, p. 186.) Dr. Buckingham and other clinicians have used the syrup of lime with success in *acute rheumatism*. (*Ibid.*, April 11, 1867.) Trousseau employed it in the *chronic diarrhœa of infants*, and recommends adding about eight minims of the syrup to each quart of milk taken. He gives the saturated syrup to a child in the quantity of from fifteen to thirty minims (0·92–1·85 C.c.) in the course of the day; to an adult, five times that quantity. Saccharated solution of lime may be used in *diarrhœa with acidity*, in *vomiting*, in *affections of the urinary organs* requiring antacid treatment, and for all other purposes to which lime is therapeutically applied. The dose equivalent to a fluidounce of lime water is twenty minims (1·25 C.c.).

SYRUPUS CASCARÆ AROMATICUS. Br. Aromatic Syrup of Cascara.

(SY-RŪ'PUS CĂS'CA-RÆ ĂR-Ō-MĂT'I-CŪS.)

"Liquid Extract of Cascara Sagrada, 8 *fl. ounces* (Imperial measure) or 400 cubic centimetres; Tincture of Orange, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Cinnamon Water, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Syrup, 6 *fl. ounces* (Imp. meas.) or 300 cubic centimetres. Mix." *Br.*

This is a new syrup of the Br. Pharm. 1898. It forms a convenient means of administering cascara, the alcohol being added to aid its preservation. The dose is from one-half to two fluidrachms (1·9–7·5 C.c.).

SYRUPUS CHLORAL. Br. Syrup of Chloral.

(SY-RŪ'PUS CHLŌ'RAL.)

"Chloral Hydrate, 1600 *grains* or 91·43 grammes; Distilled Water, 30 *fl. drachms* (Imperial measure) or 93·75 cubic centimetres; Syrup, *a sufficient quantity*. Dissolve the Chloral Hydrate in the Distilled Water; add the Syrup until the mixed product measures *one pint* (Imp. meas.) or five hundred cubic centimetres." *Br.*

The adult dose, two fluidrachms (7·5 C.c.), contains twenty grains of chloral.

SYRUPUS CODEINÆ. Br. Syrup of Codeine.

(SY-RŪ'PŬS CŌ-DE-Ī'NÆ.)

"Codeine Phosphate, 40 *grains* or 4·57 grammes; Distilled Water, ¼ *fl. ounce* (Imperial measure) or 12·5 cubic centimetres; Syrup, 19¾ *fl. ounces* (Imp. meas.) or 987·5 cubic centi-

* *Liquid Glue.* It is stated that a very adhesive glue, remaining liquid at ordinary temperatures, may be prepared by dissolving glue in a solution of saccharate of lime. (*A. J. P.*, 1872, 562.)

metres. Dissolve the Codeine Phosphate in the Distilled Water; add the Syrup; mix. 1 fluidrachm of this Syrup contains ¼ grain of Codeine Phosphate." *Br.*

This new syrup of the Br. Ph. 1898 is intended to furnish a convenient method of using codeine phosphate. The dose is from one half to two fluidrachms (1·9–7·6 C.c.).

SYRUPUS FERRI IODIDI. U. S., Br. Syrup of Ferrous Iodide.

(SY-RŪ'PUS FĔR'RĪ Ī-ŎD'Ī-DĪ.)

"A syrupy liquid containing about 10 per cent., by weight, of Ferrous Iodide [FeI_2 = 308·94], or about 13·4 Gm. in 100 C.c." *U. S.*

Syrup of Iodide of Iron; Syrupus Ferri Iodati, *P. G.;* Sirop d'Iodure de Fer, *Fr.;* Eisenjodürsyrup, *G.*

"Iron, in the form of fine bright wire, and cut into small pieces, *twenty-five grammes* [or 386 grains]; Iodine, *eighty-three grammes* [or 2 ounces av., 406 grains]; Syrup, Distilled Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Iron into a flask of thin glass, having a capacity of about *five hundred cubic centimeters* [or 16 fluidounces, 435 minims], add to it *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Distilled Water, and afterwards the Iodine. Shake the mixture occasionally, checking the reaction, if necessary, by the affusion of cold water, and, when the solution has acquired a greenish color, and has lost the odor of Iodine, heat it to boiling. Then filter it through a strong, double, rapidly-acting filter placed in a funnel, the point of which dips below the surface of *six hundred grammes* [or 21 ounces av., 72 grains] of Syrup contained in a tared vessel. When the liquid has run through, wash the flask and filter with a mixture of *twenty-five cubic centimeters* [or 406 minims], each, of Syrup and Distilled Water, previously raised to near 100° C. (212° F.), then withdraw the funnel, add enough Syrup to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains], and mix thoroughly. Keep the Syrup in small, well-stoppered, and completely filled bottles." *U. S.*

"Iron, in wire, ½ *ounce* (Imperial) or 25 grammes; Iodine, 726 *grains* or 83 grammes; Refined Sugar, 16½ *ounces* (Imp.) or 825 grammes; Distilled Water, *a sufficient quantity*. Add the Refined Sugar to *six fluid ounces* (Imp. meas.) or three hundred cubic centimetres of boiling Distilled Water and heat until dissolved. Dilute *half a fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of the resulting syrup with an equal volume of Distilled Water and set aside. Digest the Iodine and the Iron wire in a flask with *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of Distilled Water; heat gently, and finally boil slightly, until the froth loses its yellow color; filter the liquid while still hot into the syrup, washing the flask and the filter with the diluted syrup previously set aside and now heated to boiling. Pass sufficient boiling Distilled Water through the filter to produce, when cold, *one pint* (Imp. meas.) or one thousand cubic centimetres. Mix. The Syrup should have a specific gravity of 1·380 to 1·387. 11 minims of this Syrup contain 1 grain of ferrous iodide." *Br.*

These preparations furnish solutions of ferrous iodide rendered more permanent by sugar. The mode of making the iodide is precisely the same as that given under the head of *Ferri Iodidum*. The iodine should be dry; for, if moist, as commercial iodine often is, less ferrous iodide will be formed and the syrup will be proportionally weaker. In both processes a large excess of iron is taken, although the excess was reduced in the Br. Ph. 1898. A moderate excess is useful in preventing the solution of ferrous iodide from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. The method adopted in the Pharmacopœia of 1880, of filtering the unprotected solution of ferrous iodide into the sugar contained in an open capsule, and afterward straining the syrup through linen, was directly opposed to the experience of many practical pharmacists, and to the views which had been hitherto held of the action of the air upon the solution of ferrous iodide, and although with care, in skilful hands, oxidation may have been avoided, nothing was gained in time. There can be no question as to the superiority of the process of the Pharmacopœia of 1890, which is practically identical with the U. S. 1870 process. An improvement in this, however, would be to heat the syrup to boiling immediately before filtering the solution of ferrous iodide into it. Assuming that the iodine without loss is all converted into ferrous iodide, it is easy to calculate the strength of the official solutions. Thus, it will be found that the U. S. syrup contains about 7·64 grains, and that of the British Pharmacopœia 5·45 grains, of the dry iodide to the fluidrachm. In both preparations there is sufficient sugar to constitute a syrup,—the present U. S. process differing in this respect from that of 1850, which was denominated a solution, because containing insufficient sugar to be entitled to the name of a syrup. Indeed, the proportion of sugar in the

old formula was insufficient duly to protect the iodide, and was therefore increased. In the solution of 1850, a coil of iron wire, or a strip of bright iron, immersed in the solution, was found to assist in preserving it. Rock candy (pure crystallized sugar) has been frequently proposed as a substitute for commercial white sugar in making this Syrup; there is no doubt that it is much to be preferred.

The plan of protecting the solution of ferrous iodide from change by saccharine matter originated with M. Frederking, of Riga, who published a formula for the purpose in *Buchner's Repertorium* in 1839. The same plan was proposed in a paper by Prof. Procter, contained in the *A. J. P.* for April, 1840. In the *Journal de Pharmacie* for March, 1841, Dr. Dupasquier, of Lyons, claims to have made a pure ferrous iodide, protected by syrup of gum, as early as 1838. In the *P. J. Tr.* for August, 1841, the late Dr. A. T. Thomson published a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted by the British Pharmacopœia. For a practical process for making this syrup on a large scale, see *N. R.*, March, 1880.

Properties. The U. S. syrup of ferrous iodide is "a transparent, pale green liquid, having a sweet, strongly ferruginous taste, and a neutral reaction. Specific gravity, about 1·353 at 15° C. (59° F.). On adding a few drops of potassium ferricyanide test-solution to a small portion of the Syrup, a blue precipitate will be produced. If mixed with a little starch test-solution, and afterwards with a few drops of chlorine water, the Syrup will acquire a deep blue color. This color should not be produced in the Syrup by starch test-solution alone (absence of *free iodine*). If 1·55 Gm. (1·5447 Gm.) of the Syrup and 10 C.c. of water be introduced into a flask, and the liquid mixed, successively, with 11 C.c. of silver nitrate decinormal volumetric solution, and 5 C.c., each, of diluted nitric acid and ferric ammonium sulphate test-solution, it should not require more than about 1 C.c. of potassium sulphocyanate decinormal volumetric solution to produce a reddish-brown tint which persists after shaking (corresponding to about 10 per cent. of Ferrous Iodide)." *U. S.* "Dissolve 1 gramme of dried *sodium carbonate* in 10 cubic centimetres of *water*, in a flask of which the capacity to a mark on the neck is 100 cubic centimetres; pour into the flask 10 cubic centimetres (or 13·87 grammes) of the Syrup, and agitate the mixture occasionally until the precipitation of the iron is complete; then add more *water* to make the whole measure 100 cubic centimetres; mix and filter. 25 cubic centimetres of the filtrate, neutralized with *diluted nitric acid*, should require not less than 16 and not more than 16·5 cubic centimetres of the *volumetric solution of silver nitrate* for complete precipitation of the iodine, *solution of potassium chromate* being used as an indicator." *Br.* In regard to the former U. S. syrup, Prof. E. S. Wayne observed that, when kept for some time, it occasionally deposited grape sugar, into which the cane sugar was converted probably through the agency of hydriodic acid. According to Prof. J. M. Maisch, the solution was decomposed not only by light, but also by the action of atmospheric oxygen in bottles partly filled and frequently opened. The oxidation of the iron and the evolution of the iodine were accelerated by the action of light, when the solution was thus insecurely kept; but when the altered solution was transferred to air-tight bottles completely filled, and exposed to the direct light of the sun, it resumed its transparency, and its original tint was restored, or its color rendered much lighter. After this restoration the solution could not be the same; and it is probable that it contained some ferric iodate. The removal of the apparent defects of a solution of ferrous iodide by the action of sunlight is, therefore, not an admissible expedient, because it changes the nature of the solution. The same may be said of the addition of tartaric or citric acid, which has been proposed for clearing the discolored syrup. Syrup of ferrous iodide is rendered brown by sulphuric acid, and emits violet vapors when heated.

Dr. Squibb states, in a communication to the *A. J. P.* (March, 1868, p. 99), that, after considerable experience with the U. S. preparation, he has known it to become discolored in only one instance: so that with care to avoid all injurious exposure it may be expected to keep well. But, in consequence of the facility with which it undergoes decomposition, with the liberation of iodine, it is very liable to become discolored with the least want of care. He therefore proposes, as a remedy for this inconvenience, to add to the discolored syrup a very small proportion of a solution of sodium hyposulphite, which, without injury to the preparation, removes the color and in a great degree restores the transparency. For this purpose fifteen or twenty grains of the crystallized hyposulphite may be dissolved in a fluidounce of water; and from fifteen to twenty mimims of the solution are sufficient for a pint of syrup, if not darker than brown sherry. The solution is simply added to the syrup, and shaken up with

it in the bottle. If the discoloration be deeper, more will be required; and the quantity requisite for the effect is a measure of the amount of change that may have occurred. The objection to the use of this salt is that a precipitate of sulphur usually takes place which is so fine that it is very difficult to separate. Prof. J. F. Judge (*A. J. P.*, 1876, p. 159) recommended hypophosphorous acid in small proportions to restore the pale green color, and of all the additions that have been proposed this is unquestionably the least objectionable and the most effective. (See *Liquor Ferri Iodidi*, National Formulary, PART II.; also *Year-Book of Pharmacy*, 1885, p. 484.) Charles Rice preserves syrup of ferrous iodide successfully on the large scale by storing it in vessels having a stopcock at the bottom and pouring a small quantity of pure olive oil upon the surface to protect from oxidation. A. G. Hammer proposes the addition of syrup to a boiling solution of ferrous iodide before filtering from the excess of iron, and attributes the success in preservation to the fact that a portion of the cane sugar is converted into grape sugar, which he believes has greater powers in preventing change. (*Pharmacist*, 1876, p. 99.) Glycerin has been proposed as a substitute for sugar in this preparation: it answers the same purpose, but it may be doubted whether more effectually. Glucose or solution of grape sugar has been repeatedly recommended as superior to ordinary syrup for use in this preparation; when the glucose is pure, it is superior as a preservative.

When the syrup is concentrated it becomes brown, and when evaporated to dryness forms a mass which may be called *saccharine ferrous iodide*, and which is not entirely soluble again, a little ferric oxide being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt, and may be made into pills, but this preparation is inferior to the official *Ferri Iodidum Saccharatum* (see p. 620).

Medical Properties. These have been detailed under the head of *Ferri Iodidum*. Dose, from fifteen to thirty minims (0·9–1·9 C.c.), diluted with water. The dilution should be made at the moment it is taken; and, in order to guard against injury to the teeth, the mouth should be carefully washed after each dose.

SYRUPUS FERRI PHOSPHATIS. Br. Syrup of Ferrous Phosphate.

(SY-RŪ'PUS FĔR'RĪ PHŎS-PHĀ'TĪS.)

Sirop de Phosphate de Fer, *Fr.*; Eisenphosphatsyrup, *G.*

"Iron, in wire, 75 *grains* or 8·6 grammes; Concentrated Phosphoric Acid, 1¼ *fl. ounces* (Imperial measure) or 62·5 cubic centimetres; Syrup, 14 *fl. ounces* (Imp. meas.) or 700 cubic centimetres; Distilled Water, *a sufficient quantity*. Place the Iron wire and the Concentrated Phosphoric Acid, previously diluted with an equal volume of Distilled Water, in a small flask; plug the neck with cotton wool, and heat gently until the Iron is dissolved. When cold, filter into the Syrup, and pass a sufficient quantity of Distilled Water through the filter to make the product measure *one pint* (Imp. meas.) or one thousand cubic centimetres. 1 fluid drachm of this Syrup represents 1 grain of anhydrous ferrous phosphate." *Br.*

The process for this syrup of the Br. Pharmacopœia has been greatly improved. H. W. Jones (*P. J. Tr.*, 3d ser., v. 541) proposed a formula in which the phosphate was made directly from metallic iron and phosphoric acid. R. Wright (*P. J. Tr.*, 1893, 191) improved the formula, and this method is superior to the cumbersome process of preparing a precipitate of ferric phosphate and dissolving it in phosphoric acid. The syrup is a solution of ferrous phosphate protected by sugar. The sp. gr. is about 1·270. (Umney.) For its properties and uses, see *Ferri Phosphas*. The dose is from one to two fluidrachms (3·7–7·5 C.c.).

SYRUPUS FERRI QUININÆ ET STRYCHNINÆ PHOSPHATUM. U. S. (Br.) Syrup of the Phosphates of Iron, Quinine, and Strychnine.

(SY-RŪ'PUS FĔR'RĪ QUĪ-NĪ'NÆ ĔT STRŸCH-NĪ'NÆ PHŎS-PHĀ'TŬM.)

Syrupus Ferri Phosphatis cum Quinina et Strychnina, *Br.*, Syrup of Phosphate of Iron with Quinine and Strychnine.

"Soluble Ferric Phosphate, *twenty grammes* [or 309 grains]; Quinine Sulphate, *thirty grammes* [or 1 ounce av., 25 grains]; Strychnine, *two-tenths of a gramme* [or 3 grains]; Phosphoric Acid, *forty-eight cubic centimeters* [or 1 fluidounce, 299 minims]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Syrup, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Heat the Soluble Ferric Phosphate with the Water, in a porcelain capsule, until it is dissolved. Then add the Phosphoric Acid, the Quinine Sulphate, and the Strychnine, and stir, until solution is effected. Filter the liquid into the Glycerin, contained

in a graduated bottle, add enough Syrup to make up the volume to *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and mix thoroughly. Lastly, strain, if necessary." *U. S.*

"Iron, in wire, 75 *grains* or 8·6 grammes; Concentrated Phosphoric Acid, 1¼ *fl. ounces* (Imperial measure) or 62·5 cubic centimetres; Strychnine, in powder, 5 *grains* or 0·57 gramme; Quinine Sulphate, 130 *grains* or 14·8 grammes; Syrup, 14 *fl. ounces* (Imp. meas.) or 700 cubic centimetres; Distilled water, *a sufficient quantity*. Place the Iron wire and the Concentrated Phosphoric Acid, previously diluted with an equal volume of Distilled Water, in a small flask; plug the neck with cotton wool, and heat gently until the Iron is dissolved; in the resulting solution dissolve the Strychnine and Quinine Sulphate; filter into the Syrup; pass sufficient Distilled Water through the filter to make the product measure *one pint* (Imp. meas.) or one thousand cubic centimetres. One fluid drachm of this Syrup represents 1 grain of anhydrous ferrous phosphate, $\frac{4}{5}$ grain of Quinine Sulphate, and $\frac{1}{32}$ grain of Strychnine." *Br.*

The ferric phosphate used in the U. S. preparation is the scaled salt (see p. 626), and the phosphoric acid the 85 per cent. solution (see p. 78). Glycerin has been added in the U. S. 1890 process to prevent precipitation. Each fluidrachm of the syrup contains about one grain of ferric phosphate, one grain and three-quarters of quinine, and $\frac{1}{90}$ of a grain of strychnine. The process for the British syrup directs the preparation of a fresh solution of *ferrous* phosphate from iron wire and phosphoric acid, as suggested by Wright (*P. J. Tr.*, 1893, 19); it contains less quinine and strychnine and is more permanent than the U. S. syrup. Discoloration, due to light, is usually noticed in this syrup, and it has been repeatedly suggested that glucose be substituted for syrup to prevent this fault. An insoluble precipitate of basic ferric phosphate is apt to be produced when this syrup is kept.

Medical Properties. This syrup has the medicinal activities of its ingredients, but is a very ineligible preparation, and has not even an agreeable taste to excuse its polypharmacy. It is known as *Easton's Syrup*, *Aitkin's Syrup*, *Syrup of the Three Phosphates*, and *Syrup of Triple Phosphates*. A teaspoonful (3·7 C.c.) may be considered to be the average dose.

SYRUPUS GLUCOSI. Br. Syrup of Glucose.

(SỲ-RŪ′PŲS GLŲ-CŌ′SĪ.)

"Liquid Glucose, of commerce, 1 *ounce* (Imperial) or 25 grammes; Syrup, 2 *ounces* (Imp.) or 50 grammes. Mix, by the aid of gentle heat." *Br.*

This is a new preparation of the Br. Ph. 1898. It may be used as a vehicle for syrups which contain chemical salts liable to discoloration through the action of light; but its principal use is to take the place of *treacle* or molasses so much used in British pharmacy as a pill excipient. (See *Pilulæ*, p. 1038.)

SYRUPUS HEMIDESMI. Br. Syrup of Hemidesmus.

(SỲ-RŪ′PŲS HĔM-Ị-DĔS′MĪ.)

Syrup of Indian Sarsaparilla; Sirop de Hemidesmus, *Fr.*; Hemidesmussyrup, *G.*

"Hemidesmus Root, bruised, 4 *ounces* (Imperial) or 100 grammes; Refined Sugar, 28 ounces (Imp.) or 700 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 500 cubic centimetres. Infuse the Hemidesmus Root in the Distilled Water, in a covered vessel, for four hours, and strain. Set the infusion aside until clear; then decant the clear liquid, add the Refined Sugar, and dissolve by the aid of gentle heat. The weight of the product should be *forty-two ounces* (Imp.) or one thousand and fifty grammes." *Br.*

This is a very weak preparation. The dose is stated at one fluidrachm (3·7 C.c.); but the syrup may be taken almost *ad libitum*. (See *Hemidesmus*.)

SYRUPUS HYPOPHOSPHITUM. U. S. Syrup of Hypophosphites.

(SỲ-RŪ′PŲS HĬ-PŌ-PHŌS-PHĪ′TŬM.)

Sirop de Hypophosphites, *Fr.*

"Calcium Hypophosphite, *forty-five grammes* [or 1 ounce av., 257 grains]; Potassium Hypophosphite, *fifteen grammes* [or 231 grains]; Sodium Hypophosphite, *fifteen grammes* [or 231 grains]; Diluted Hypophosphorous Acid, *two grammes* [or 31 grains]; Sugar, *five hundred grammes* [or 17 ounces av., 279 grains]; Spirit of Lemon, *five cubic centimeters* [or 81 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Triturate the Hypophosphites with *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Water, until they are dissolved, add the Spirit of Lemon, and the Hypophosphorous Acid, and filter the liquid. In the filtrate dissolve the Sugar by agitation, without heat, and add enough Water, through the filter, to make the product measure

one thousand cubic centimeters [or 33 fluidounces, 390 minims]. Strain if necessary. *Syrup of Hypophosphites* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This syrup is a simple solution of calcium, sodium, and potassium hypophosphites, in water, protected by sugar, and flavored with spirit of lemon. The calcium hypophosphite will usually not entirely dissolve: hence the direction to use hypophosphorous acid to complete the solution. Percolation will no doubt be preferred by many to agitation, for dissolving the sugar. It has been stated that the sulphuretted odor sometimes noticed in this syrup is due to the decomposition of sulphates or sulphites (present as impurities in the salts) by the hypophosphorous acid. (*P. J. Tr.*, 1895, 143.) Each fluidrachm of the syrup contains about two and a half grains of calcium hypophosphite, and not quite one grain each of the sodium and potassium salts. This syrup affords an excellent means of administering the hypophosphites. Dose, from one to two fluidrachms (3·7–7·5 C.c.).

SYRUPUS HYPOPHOSPHITUM CUM FERRO. U. S. Syrup of Hypophosphites with Iron.

(SY-RŪ'PUS HĪ-PO-PHŌS-PHĪ'TUM CŬM FĔR'RŌ.)

Sirop d'Hypophosphite avec Fer, *Fr.*

"Ferrous Lactate, *ten grammes* [or 154 grains]; Potassium Citrate, *ten grammes* [or 154 grains]; Syrup of Hypophosphites, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Ferrous Lactate and Potassium Citrate with a small quantity of the Syrup, gradually added, until they are dissolved. Then strain, and add enough Syrup of Hypophosphites to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. This preparation should be freshly made when wanted." *U. S.*

This syrup, which was made official in the U. S. P. 1880 for the first time, has been the subject of considerable pharmaceutical discussion because of the difficulty of selecting a salt of iron which would remain in solution and not form a precipitate with the other salts. The lactate has been selected as the least objectionable in this respect, and the combination with the alkaline citrate is with the view of retaining the salts in solution in the syrup. Cloudiness in the syrup may be prevented, according to Ott, by dissolving the ferrous lactate and potassium citrate in *hot* syrup and adding this to the syrup of hypophosphites. The syrup of hypophosphites with iron now contains in each fluidrachm about two and a half grains of calcium hypophosphite, with nearly one grain each of sodium and potassium hypophosphites, and three-fourths of a grain of ferrous lactate.* It unites the therapeutic powers of a chalybeate with those of the hypophosphites. Dose, from one to two fluidrachms (3·7–7·5 C.c.).

SYRUPUS IPECACUANHÆ. U. S. Syrup of Ipecac.

(SY-RŪ'PUS ĬP-Ē-CĂC-Ū-ĂN'HÆ.)

Sirop d'Ipécacuanha, *Fr.*; Ipecacuanhasyrup, *G.*

"Fluid Extract of Ipecac, *seventy cubic centimeters* [or 2 fluidounces, 176 minims]; Acetic Acid, *ten cubic centimeters* [or 162 minims]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dilute the Fluid Extract of Ipecac with *three hundred cubic centimeters* [or 10 fluidounces, 69

* *Syrup of Hypophosphites with Iron.* Owing to the liability to change of ferrous lactate in the presence of an excess of hypophosphites, Mr. C. D. Randall substitutes ferric citrate for it, with good results, and gives the following process: Take of Calcium Hypophosphite 554 parts [or 591 grains]; Sodium Bicarbonate 95 parts [or 101 grains]; Potassium Bicarbonate 115 parts [or 123 grains]; Ferric Citrate 85 parts [or 91 grains]; Sugar, powdered, 4050 parts [or 9 troyounces]; Water a sufficient quantity to make 10,000 parts [or 16 fluidounces]. Dissolve the calcium hypophosphite, previously reduced to a fine powder, in 3500 parts [or 8 fluidounces] of water with the aid of heat, and add to the solution the sodium bicarbonate, continuing the heat until action has entirely ceased. After removing the solution from the heat, add the potassium bicarbonate in small portions, waiting after each addition until effervescence has ceased before adding more. When action has entirely ceased, filter the liquid through paper. After the liquid has ceased to drop, add enough water through the filter to make the filtrate weigh 5850 parts [or measure 10 fluidounces]. In 1200 parts [or 2 fluidounces] of this liquid dissolve the ferric citrate with the aid of heat, and add the solution to the remainder of the liquid. In this solution dissolve the sugar with or without the aid of heat and filter through paper, adding through the filter enough water to make the completed syrup weigh 10,000 parts [or measure 16 fluidounces]. (*A. J. P.*, 1884, p. 357.)

minims] of Water, to which the Acetic Acid had previously been added, and mix them thoroughly by shaking. Then filter, and pass enough Water through the filter to obtain *four hundred and fifty cubic centimeters* [or 15 fluidounces, 100 minims] of filtrate. To this liquid add the Glycerin, dissolve the Sugar in the mixture, and add enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly, and strain, if necessary. *Syrup of Ipecac* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Mix the filtrate obtained as directed in the preceding formula with the Glycerin, pour the mixture upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

By the U. S. process of 1850, a tincture of ipecac was first formed with diluted alcohol, then reduced by evaporation so as to drive off the alcohol, and afterwards diluted with water and made into a syrup with sugar. The French Codex dissolves the alcoholic extract of ipecac in water, and then mixes it with syrup; but it is obvious that the U. S. plan was preferable, as it spared the continued heat requisite to reduce the tincture to dryness. The present U. S. syrup, which is very slightly stronger than that of 1870, is made in accordance with the suggestions of Mr. Laidley, of Richmond, Va., who found the syrup, as ordinarily prepared, to spoil by keeping. (*A. J. P.*, xxvi. 103, and July, 1879.) (See a practical paper on this subject by A. Robbins in *A. J. P.*, Aug. 1879.) The substitution of glycerin for a portion of the syrup in the U. S. 1890 process is an improvement; but the addition of the very small quantity of Acetic Acid is of questionable utility. For formulæ in which the drug ipecac is employed, the reader may consult *A. J. P.*, 1870, p. 127; 1871, p. 104; May, 1881.

If strictly official (1890) fluid extract of ipecac be used in making this syrup, and the process be carried out in all its details, the syrup will remain transparent; but if commercial fluid extract be used, or if the fluid extract have not been very carefully made, it will be necessary to modify the process somewhat to secure a transparent syrup. This may be effected by allowing the diluted fluid extract in the official process for making this syrup to remain for two or three days in a cool place before filtering.

One fluidounce of this syrup should contain the virtues of about thirty grains of ipecac. Dose, as an emetic, for an adult, from four fluidrachms to a fluidounce (15–30 C.c.), for a child a year or two old, from thirty minims to a fluidrachm (1·9–3·7 C.c.), repeated every fifteen or twenty minutes till it acts. As an expectorant, the dose for an adult is from thirty minims to a fluidrachm (1·9–3·7 C.c.), for a child from two to ten minims (0·12–0·6 C.c.).

SYRUPUS KRAMERIÆ. U. S. Syrup of Krameria.

(SY-RŪ'PUS KRĄ-MĒ'RI-Æ.)

Syrupus Ratanhæ; Sirop de Ratanhia, *Fr.*; Ratanhasyrup, *G.*

"Fluid Extract of Krameria, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]; Syrup, *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

This syrup is more conveniently made by the present process than by either of those of the U. S. Pharmacopœia of 1860,—in the first of which the powdered root was exhausted with water, the percolate evaporated, and the sugar dissolved in it by a gentle heat; while in the second process, extract of krameria was dissolved in syrup. As krameria yields a variable proportion of extract, it follows that the syrup resulting from these two modes of preparation must have differed. To obviate this evil as far as possible, care had to be taken, in following the first process, to select the best krameria, and preferably the small roots, as it was these only which would yield two ounces of good extract to the pound. We have found the syrup made from the official fluid extract perfectly transparent, and not a turbid mixture, as stated by some writers. This preparation affords a convenient mode of exhibiting krameria. The dose for an adult is half a fluidounce (15 C.c.), for a child a year or two old, from twenty to thirty minims (1·25–1·9 C.c.).

SYRUPUS LACTUCARII. U. S. Syrup of Lactucarium.

(SY-RŪ'PUS LĂC-TŪ-CĀ'RI-Ī.)

Sirop de Lactucarium, *Fr.*; Lactucariumsyrup, *G.*

"Tincture of Lactucarium, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Precipitated Calcium Phosphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sugar, *seven hun-*

dred and fifty grammes [or 26 ounces av., 199 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Triturate the Precipitated Calcium Phosphate and *one hundred and fifty grammes* [or 5 ounces av., 127 grains] of the Sugar, in a mortar, with the Tincture of Lactucarium gradually added, and afterwards with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, added in small portions at a time. Filter the mixture, dissolve the remainder of the Sugar in the filtrate, and pass enough Water through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Syrup of Lactucarium* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

The formula of the U. S. P. 1870 was very objectionable, and the syrup was rarely used, on account of its want of transparency, and in some measure also because of its disagreeable taste. The former of these objections it was proposed to obviate by the use of magnesium carbonate, as in the former U. S. formula for Syrup of Tolu; the latter, by the addition of one of the aromatic Waters. The rubbing with magnesium carbonate enabled the menstruum to take up, as far as it was capable of doing, the matter that would otherwise have been deposited. The use of powdered pumice-stone instead of magnesium carbonate, and the rubbing of this and a little sugar with the tincture after evaporation instead of previously, were recommended by Mr. James Kenworthy. The result was a beautifully clear syrup, with the flavor and appearance of Aubergier's, and the virtues of that of the U. S. Pharmacopœia. (*A. J. P.*, March, 1868, p. 113.)* But the present process, if official tincture of lactucarium be used, is far preferable, the only disadvantage being the slight petroleum-like taste which seems to be inseparable from lactucarium preparations made by extracting the resinous principles with benzin: the new tincture of lactucarium, notwithstanding all the care that can be given to the selection of the benzin, will still hold a trace of the benzin-residue flavor, which it communicates to the syrup. The recommendations made by various pharmaceutical writers to add a solution of an alkali to cloudy syrup of lactucarium, in order to make it transparent, are inadmissible, for Aubergier has conclusively shown that alkalies destroy the bitter principles of lactucarium. The dose is from two to three fluidrachms (7·5–11·25 C.c.).

Mr. Jos. W. England and N. D. Streeter both prefer to make the syrup directly from the lactucarium. For processes, see *A. J. P.*, 1883, pp. 393, 593.

SYRUPUS LIMONIS. Br. Syrup of Lemon.

(SY-RŬ'PUS LI-MŌ'NĬS.)

Syrupus Succus Citri, *P. G.;* Sirop de Limons (de Citrons), *Fr.;* Citronensaftsyrup, *G.*

"Fresh Lemon Peel, in thin slices or grated, 1 *ounce* (Imperial) or 20 grammes; Alcohol (90 per cent.), *a sufficient quantity;* Lemon Juice, 25 *fl. ounces* (Imp. meas.) or 500 cubic cen-

* *Aubergier's Syrup of Lactucarium.* Though probably inferior in efficacy to the U. S. syrup, that of Aubergier has a great reputation on the continent of Europe, and is occasionally prescribed here instead of the official. It differs so much from ours that, when it is prescribed, pharmacists who may not have it on hand should not substitute the official for it, unless with the full knowledge of the prescriber. In order to obviate this inconvenience, it is advisable that there should be a formula, readily accessible, by which a syrup may be prepared sufficiently representing Aubergier's for all practical purposes. Prof. Procter, therefore, did the profession good service by preparing and publishing such a process, which we copy here. "Take of Lactucarium (German) *half an ounce;* Granulated Sugar *an ounce;* Simple Syrup *four and a half pints;* Citric Acid, in powder, *sixty grains;* Orange Flower Water *four fluidounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Triturate the Lactucarium with the Sugar until reduced to powder, put it into a funnel-shaped percolator, pour on Diluted Alcohol until the Lactucarium is nearly exhausted, or until ten fluidounces have passed, evaporate to two fluidounces, and add it to the Syrup, previously heated by boiling, and mix. Continue the ebullition slowly until the whole measures four pints and six fluidounces. Then add the Citric Acid and strain, and, lastly, when nearly cool, the Orange Flower Water, and mix them. Each fluidounce represents three and one-third grains of lactucarium. The syrup is light brown and transparent." (*A. J. P.*, 1866, p. 290.)

The French Codex has a syrup, called *Opiated Syrup of Lactucarium* (*Sirop de Lactucarium opiacé*), in which an alcoholic extract is used in double the quantity of extract of opium. One would suppose that in such a proportion the action of the opium would entirely overwhelm that of the lactucarium; but Dr. Geo. B. Wood was assured by M. Deschamps, as the well-ascertained result of experiments of his own and the late M. Debout's, that lactucarium given with opium, even in small proportion, very decidedly opposes the unpleasant effects caused by opium, such as nausea, stomachic spasms, headache, etc. (*Ann. de Thérap.*, 1868, p. 17); and hence the advantage of a preparation in which the two narcotics are combined. But to gain all the good results of this experience it is unnecessary to add a new syrup to the official list, all that is requisite being the addition of a little of the simple syrup of lactucarium to any preparation of opium the anticipated unpleasant effects of which it is desirable to prevent.

timetres; Refined Sugar, 38 *ounces* (Imp.) or 760 grammes. Macerate the Lemon Peel in *one fluid ounce and a half* (Imp. meas.) or thirty cubic centimetres of the Alcohol for seven days; press; filter; add sufficient of the Alcohol to produce *two fluid ounces* (Imp. meas.) or forty cubic centimetres. In the Lemon Juice, clarified by subsidence, dissolve the Refined Sugar by the aid of gentle heat. When the resulting syrup is cold, mix with it the *two fluid ounces* (Imp. meas.) or forty cubic centimetres of alcoholic liquid. The product should weigh *four pounds and one ounce* (Imp.) or thirteen hundred grammes." *Br.*

The U. S. P. 1880 syrup of lemon was dropped at the 1890 revision: as it is frequently used, the process will be found in the foot-note.* The addition of lemon peel to the preparation is an improvement, but the internal white portion of the peel should be carefully removed before adding to the hot lemon juice, or the finished syrup will have a bitter taste. (See *Limonis Cortex.*) As the syrup is used exclusively as a vehicle, and has no medical properties, the improvement of diluting the juice with an equal measure of water should have been retained. This syrup forms a cooling and grateful addition to beverages in *febrile complaints*, and serves to conceal the taste of saline purgatives in solution.

SYRUPUS PICIS LIQUIDÆ. U. S. Syrup of Tar.

(SY-RŪ'PUS PĪ'CĬS LĬQ'UĮ-DÆ—lĭk'wę-dē.)

Sirop de Goudron, *Fr.;* Theersyrup, *G.*

"Tar, *seventy-five grammes* [or 2 ounces av., 282 grains]; Water, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Boiling Distilled Water, *four hundred cubic centimeters* [or 13 fluidounces, 252 minims]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Tar intimately with about *one hundred grammes* [or 3 ounces av., 231 grains] of white sand, pour on the Water, and stir frequently during twelve hours; then pour off the Water and throw it away. Pour the Boiling Distilled Water upon the residue, stir well and frequently during fifteen minutes, add the Glycerin, and set the vessel aside for twenty-four hours, occasionally stirring. Decant the clear solution, and filter. Dissolve the Sugar in the filtrate with the aid of a gentle heat; allow the liquid to cool, then strain it, and pass enough Distilled Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This syrup will probably be found one of the most useful additions to the list of official syrups. In many sections of our country it has been largely used. The process of the U. S. P. 1890 is an improvement on the one formerly official: the sugar is now dissolved with the aid of a gentle heat, whilst the addition of glycerin prevents possible turbidity. The preliminary washing of the tar will doubtless be regarded by many as a useless refinement, but it should on no account be omitted, as otherwise a syrup which would be irritant rather than soothing might be produced, owing to the acid constituents always present in tar. (See *Pix Liquida.*) This syrup affords an excellent method of administering tar. Dose, from one to two fluidrachms (3·7–7·5 C.c.).

SYRUPUS PRUNI VIRGINIANÆ. U. S., Br. Syrup of Wild Cherry.

(SY-RŪ'PUS PRŪ'NĪ VĬR-ĢĬN-Į-Ā'NÆ.)

Syrup of Virginian Prune, *Br.* 1898; Sirop d'Ecorce de Cerisier, *Fr.;* Wildkirschenrindensyrup, *G.*

"Wild Cherry, in No. 20 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Glycerin, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water. Moisten the Wild Cherry with a sufficient quantity of the liquid, and macerate for twenty-four hours in a close vessel; then pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid has disappeared from the surface, follow it by Water, until the percolate measures *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]. Dissolve

* "Lemon Juice, recently expressed and strained, *forty parts* [or seventeen fluidounces]; Fresh Lemon Peel, *two parts* [or one ounce av.]; Sugar, in coarse powder, *sixty parts* [or twenty-eight ounces av.]; Water, *a sufficient quantity*, To make *one hundred parts* [or about two pints]. Heat the Lemon Juice to the boiling point; then add the Lemon Peel, and let the whole stand, closely covered, until cold. Filter, add enough Water through the filter to make the filtrate weigh *forty parts* [or measure seventeen fluidounces], dissolve the Sugar in the filtered liquid by agitation, without heat, and strain." *U. S.*

the Sugar in the percolate by agitation, without heat, strain, and pass enough Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Syrup of Wild Cherry* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the percolate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Virginian Prune Bark, in No. 20 powder, 3 *ounces* (Imperial) or 150 grammes; Refined Sugar, in coarse powder, 15 *ounces* (Imp.) or 750 grammes; Glycerin, 1¼ *fl. ounces* (Imp. meas.) or 62·5 cubic centimetres; Distilled Water, *a sufficient quantity*. Moisten the Virginian Prune Bark with Distilled Water; set aside for twenty-four hours in a closed vessel; pack in a percolator; gradually add Distilled Water until the quantity of *nine fluid ounces* (Imp. meas.) or four hundred and fifty cubic centimetres of percolate has been collected; dissolve the Refined Sugar in the liquid by agitation, without heat; add the Glycerin; strain; pour sufficient Distilled Water over the strainer to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Syrup." *Br.*

The British Pharmacopœia introduced this syrup into the 1898 edition. The process is modelled after the U. S. formula, with one exception,—*i.e.*, in the use of the glycerin; this should be added to the percolate to preserve the cold infusion from decomposition, which is likely to occur in warm weather.

The U. S. process affords a handsome syrup, with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Messrs. Procter and Turnpenny in *A. J. P.* (xiv. 27). The suggestion made in the 16th edition of this work to increase the quantity of glycerin has been adopted in the present process: the glycerin prevents precipitation. This syrup should never be made by adding fluid extract to simple syrup, as the fluid extract is apt to vary greatly in quality, and frequently precipitates when mixed with syrup. The syrup when made by the above process is far superior in flavor and active properties, and is largely used as a basis for cough mixtures. The dose for an adult is half a fluidounce (15 C.c.).

SYRUPUS RHEI. U. S., Br. Syrup of Rhubarb.

(SY-RŪ'PUS RHĒ'Ī.)

Sirop de Rhubarbe, *Fr.*; Rhabarbersaft, *G.*

"Fluid Extract of Rhubarb, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Spirit of Cinnamon, *four cubic centimeters* [or 65 minims]; Potassium Carbonate, *ten grammes* [or 154 grains]; Glycerin, *fifty cubic centimeters* [or 1 fluidounce, 332 minims]; Water, *fifty cubic centimeters* [or 1 fluidounce, 332 minims]; Syrup, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Spirit of Cinnamon with the Fluid Extract of Rhubarb, and add to it the Potassium Carbonate dissolved in the Water. Then add the Glycerin, and, lastly, enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Rhubarb Root, in No. 20 powder, 2 *ounces* (Imperial) or 50 grammes; Coriander Fruit, in No. 20 powder, 2 *ounces* (Imp.) or 50 grammes; Refined Sugar, 24 *ounces* (Imp.) or 600 grammes; Alcohol (90 per cent.), 8 *fl. ounces* (Imp. meas.) or 200 cubic centimetres; Distilled Water, 24 *fl. ounces* (Imp. meas.) or 600 cubic centimetres. Moisten the mixed Rhubarb Root and Coriander Fruit with a portion of the mixed Alcohol and Distilled Water, and set aside; pack in a percolator; pass the remainder of the diluted alcohol slowly through the materials; evaporate the percolate until it is reduced to *fourteen fluid ounces* (Imp. meas.) or three hundred and fifty cubic centimetres, and in this, after it has been filtered, dissolve the Refined Sugar by the aid of heat. The product should weigh nearly *two and a half pounds* (Imp.) or one thousand grammes." *Br.* This is a troublesome and imperfect method.

The U. S. syrup differs from that formerly official in several particulars, and, in our opinion, it is greatly improved: the activity of the rhubarb and the corrigent effects of the cinnamon are both secured without impairing the appearance of the finished syrup, while the simplicity of the manipulation must commend the process to all. Mr. Otto Miller recommends its preparation by dissolving ninety grains of potassium carbonate in twelve fluidounces of cinnamon water, adding twenty-eight ounces of sugar, heating to the boiling point, and, when the sugar is dissolved, adding four fluidounces of fluid extract of rhubarb, straining, and bringing it to

the measure of two pints with cinnamon water. A pleasant, clear, efficient, and permanent syrup results. (*West. Drug.*, 1887, p. 107.) The syrup is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of a fluidrachm (3·7 C.c.).

SYRUPUS RHEI AROMATICUS. U. S. Aromatic Syrup of Rhubarb.

(SY-RŪ'PUS RHĒ'Ī ĂR-Ǫ-MĂT'Ị-CŬS.)

Sirop de Rhubarbe aromatique, *Fr.;* Gewürzter Rhabarbersaft, *G.*

"Aromatic Tincture of Rhubarb, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Syrup, *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

This syrup is nearly identical with that official in the U. S. P. 1870. The aromatic tincture is identical with that formerly used in the preparation of this syrup. The addition of a small amount of alkali or filtration after the use of magnesium carbonate has been recommended, to prevent the syrup from becoming turbid. The substitution of glycerin for one-half of the syrup, as recommended in the 14th edition of this work, would be an improvement.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel-complaints of infants which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use, under the name of *spiced syrup of rhubarb*. The dose for an infant with *diarrhœa* is a fluidrachm (3·7 C.c.), repeated every two hours till the passages indicate by their color that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most of the cases in which this syrup is used, might render it too stimulating in some instances of diarrhœa in the very young infant.

SYRUPUS RHŒADOS. Br. Syrup of Red Poppy.

(SY-RŪ'PUS RHŒ'Ą-DŌS—rē'ą-dōs.)

Sirop de Coquelicot de Pavot rouge, *Fr.;* Klatschrosensaft, *G.*

"Red-Poppy Petals, 13 *ounces* (Imperial) or 260 grammes; Refined Sugar, 2¼ *pounds* (Imp.) or 720 grammes; Alcohol (90 per cent.), 2½ *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Red-Poppy Petals gradually to *one pint* (Imp. meas.) or four hundred cubic centimetres of Distilled Water kept hot upon a water-bath; stir frequently, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquid; strain; add the Refined Sugar, and dissolve by the aid of heat. When nearly cold, add the Alcohol, and sufficient Distilled Water to produce *three pounds ten ounces* (Imp.) or one thousand one hundred and sixty grammes of the Syrup." *Br.*

The object of introducing the petals into water heated by a water-bath is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red color of this syrup is its only recommendation. It is very liable to ferment: according to Dr. Enders, this can be obviated by evaporating the recently prepared syrup to dryness, keeping the powdered residue in well-stopped bottles, and dissolving it, as wanted, in four-fifths of its weight of water. The dose is stated in the Br. Pharmacopœia as a fluidrachm (3·7 C.c.).

SYRUPUS ROSÆ. U. S., Br. Syrup of Rose.

(SY-RŪ'PUS RŌ'ṢÆ.)

Syrup of Roses, *Br.;* Syrupus Rosarum Rubrarum; Syrup of Red Rose; Sirop de Roses rouges, *Fr.;* Rosensyrup, *G.*

"Fluid Extract of Rose, *one hundred and twenty-five cubic centimeters* [or 4 fluidounces, 109 minims]; Syrup, *eight hundred and seventy-five cubic centimeters* [or 29 fluidounces, 282 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

"Dried Red-Rose Petals, 2 *ounces* (Imperial) or 50 grammes; Refined Sugar, 30 *ounces* (Imp.) or 750 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 500 cubic centimetres. Infuse the Red-Rose Petals in the Distilled Water for two hours; strain; press; heat the liquid to the boiling point; filter; dissolve the Refined Sugar in the liquid by the aid of heat. The product should weigh *two pounds fourteen ounces* (Imp.) or eleven hundred and fifty grammes." *Br.*

Syrup of rose is mildly astringent, but is valued most for its fine red color, on account of which it is occasionally added to mixtures. Dose, a fluidrachm (3·7 C.c.).

SYRUPUS RUBI. U. S. Syrup of Rubus.

(SY-RŪ'PUS RŪ'BĪ.)

Syrup of Blackberry Root; Sirop d'Ecorce de Ronce noir, *Fr.;* Brombeerrindensyrup, *G.*

"Fluid Extract of Rubus, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Syrup, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them." *U. S.*

This syrup is useful in *acute diarrhœa of relaxation* and in *chronic diarrhœa*. Dose, from one to two fluidrachms (3·7–7·5 C.c.).

SYRUPUS RUBI IDÆI. U. S. Syrup of Raspberry.

(SY-RŪ'PUS RŪ'BĪ Ī-DÆ'Ī.)

"Fresh, Ripe Raspberries, *any convenient quantity;* Sugar, *a sufficient quantity*. Reduce the Raspberries to a pulp, and let this stand, at a temperature of about 20° C. (68° F.), until a small portion of the filtered juice mixes clear with half its volume of alcohol. Then separate the juice by pressing, set it aside, in a cool place, until the liquid portion has become clear, and filter. To every *forty parts* by weight of the filtrate (which should not be allowed to remain, unprotected by sugar, more than about two hours) add *sixty parts* of Sugar, heat the mixture to boiling, avoiding the use of tinned vessels, and strain. Keep the product in well-stoppered bottles, in a cool and dark place." *U. S.*

This syrup has been introduced because of the large use of fruit syrups. A better selection could hardly have been made than that of the syrup of raspberry. The syrup found in the market is often artificial and colored with aniline, hence the official test. "On shaking separate portions of Syrup of Raspberries with ether, chloroform, or amylic alcohol, no color should be imparted to these liquids (absence of *foreign coloring matters*)." *U. S.* The previous fermentation of the juice frees it from albuminous and pectinous substances, which interfere with the transparency of the syrup, and, if not separated, would seriously increase the risk of its spoiling. The flavor of the juice is not injured, although the process must be carefully watched to keep the fermentation from passing from the vinous to the acetous form.

SYRUPUS SARSAPARILLÆ COMPOSITUS. U. S. Compound Syrup of Sarsaparilla.

(SY-RŪ'PUS SĂR-SA-PA-RĬL'LÆ CŌM-PŎS'Ī-TŪS.)

Sirop de Salsepareille composé, Sirop sudorifique, *Fr.;* Zusammengesetzter Sarsaparillsyrup, *G.*

"Fluid Extract of Sarsaparilla, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Fluid Extract of Glycyrrhiza, *fifteen cubic centimeters* [or 243 minims]; Fluid Extract of Senna, *fifteen cubic centimeters* [or 243 minims]; Sugar, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Sassafras, *one-tenth cubic centimeter* [or 1½ minims]; Oil of Anise, *one-tenth cubic centimeter* [or 1½ minims]; Oil of Gaultheria, *one-tenth cubic centimeter* [or 1½ minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Add the Oils (equivalent to about *two drops*, each) to the mixed Fluid Extracts, and shake the liquid thoroughly. Then add enough Water to make up the volume to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims], and mix well. Set the mixture aside for one hour, then filter it. Dissolve the Sugar in the filtrate with the aid of a gentle heat, allow the liquid to cool, strain, and add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.* An important change has been made in this compound syrup through the substitution of fluid extracts and volatile oils for the drugs used in the U. S. P. 1880 process. The new syrup is not perfectly transparent, but the U. S. P. 1880 syrup had the same fault. The simplicity of the present formula is a welcome improvement.

In the original edition of the U. S. Pharmacopœia, published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *sirop de cuisinier*. This was very much improved in the revised edition published in 1830, and the amended process has been retained with little alteration in the subsequent editions, the process of percolation having been substituted in the U. S. 1880 Pharmacopœia for simple maceration directed in the first of the two formulas of 1850. In the original process the sarsaparilla was subjected to long decoction with water. It has been proved that diluted alcohol more thoroughly extracts the acrid principle of the root, upon which its activity probably depends, than water, and that this principle is either dissipated or destroyed by the long-continued application of a boiling heat. In the

present formula, therefore, which employs diluted alcohol as the menstruum for the fluid extracts, the root is more completely exhausted of its active matter, while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers the syrup prepared by decoction and renders it liable to spoil. Yet it must be remembered, in this connection, that the constituents which are dissolved out by the alcohol are in great part afterwards precipitated by water and filtered out, and thus do not enter into the preparation. In the Pharmacopœia of 1840 the pale or hundred-leaved roses were very properly substituted for the red, as their slightly laxative property accords better with the character of the preparation. The essential oils were intended solely to communicate an agreeable flavor, and were used in very small proportion. The only objection to the 1880 process was that a portion of the resin extracted by the alcohol from the guaiacum wood was deposited during the evaporation of the tincture: this was separated by the filtration directed in the U. S. P. 1880, and was therefore of no disadvantage to the preparation. In the present process guaiacum wood is omitted: its loss, however, will never be felt. But the practitioner should be aware that much of the sarsaparilla as it exists in the market is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. Dr. Samuel Kennedy (*Pharm. Record*, 1888, p. 201) showed that when corrosive sublimate was dissolved in this syrup precipitation invariably occurred; if an equal amount of sodium chloride was added, precipitation was greatly retarded. M. Lepage, of Gisors, proposes as a substitute potassium iodohydrargyrate, which he has found not to undergo decomposition. (See PART II., and *Sirop Gibert*, p. 702.)

The dose of the syrup is half a fluidounce (15 C.c.), equivalent to somewhat less than a drachm (3·9 Gm.) of the root, to be taken three or four times a day. When a decided effect is desired, the fluid extract is much more efficient.

SYRUPUS SCILLÆ. U. S., Br. Syrup of Squill.

(SY-RŪ'PUS SÇĬL'LÆ.)

Sirop de Scille, *Fr.*; Meerzwiebelsyrup, *G.*

"Vinegar of Squill, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Heat the Vinegar of Squill to the boiling point, in a glass or porcelain vessel, and filter the liquid while it is hot. Dissolve the Sugar in the hot filtrate by agitation, without further heating, strain, and, when the strained liquid is cold, add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Vinegar of Squill, 1 *pint* (Imperial measure) or 500 cubic centimetres; Refined Sugar, 38 *ounces* (Imp.) or 950 grammes. Dissolve the Refined Sugar in the Vinegar of Squill by the aid of gentle heat. The product should weigh *three pounds ten ounces* (Imp.)." *Br.*

The present British formula is almost identical with the American, and differs from that of 1864 in taking the vinegar already formed, instead of preparing it as the first step of the process. The object of heating the vinegar to the boiling point is to coagulate albuminous matter, which is afterwards separated by filtration. The heating should be performed as quickly as possible, to prevent undue loss of acetic acid.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. It is incompatible with ammonium carbonate, but not with ammonium chloride. The dose is about a fluidrachm (3·7 C.c.). In infantile *bronchitis* it is sometimes given, in the same dose, as an emetic.

SYRUPUS SCILLÆ COMPOSITUS. U. S. Compound Syrup of Squill.

(SY-RŪ'PUS SÇĬL'LÆ CŌM-PŌS'Ĭ-TŬS.)

Hive Syrup; Sirop de Scille composé, *Fr.*; Zusammengesetzter Meerzwiebelsyrup, *G.*

"Fluid Extract of Squill, *eighty cubic centimeters* [or 2 fluidounces, 338 minims]; Fluid Extract of Senega, *eighty cubic centimeters* [or 2 fluidounces, 338 minims]; Antimony and Potassium Tartrate, *two grammes* [or 31 grains]; Precipitated Calcium Phosphate, *ten grammes* [or 154 grains]; Sugar, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Water,

a sufficient quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Fluid Extracts, evaporate them, in a tared capsule, on a water-bath, to *one hundred grammes* [or 3 ounces av., 231 grains], and mix the residue with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 407 minims] of Water. When the mixture is cold, incorporate with it, intimately, the Precipitated Calcium Phosphate, filter, pass enough Water through the filter to obtain *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of filtrate, and add to this the Antimony and Potassium Tartrate dissolved in *twenty-five cubic centimeters* [or 406 minims] of hot Water. Dissolve the Sugar in this liquid by agitation, without heat, strain, and add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Compound Syrup of Squill* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula, and mixed with the solution of Antimony and Potassium Tartrate, upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented from the want of sufficient concentration. This defect was corrected at the revision of 1840, when sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. In the Pharmacopœia of 1850 two formulas were given for this syrup, in the first of which the virtues of the squill and senega were extracted by long boiling with water, in the second by percolation with water to which a small portion of alcohol was added. The latter was preferable when skilfully performed, as it avoided in great measure the injurious influence of boiling upon the senega, exhausted both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and afforded a solution of their active principles less embarrassed with inert matters calculated to favor fermentation. In this process the filtered liquor was raised to the boiling point in order to coagulate the albumen, after which the evaporation was conducted at a lower temperature. The present formula is a decided improvement upon the one just described; as, diluted alcohol being employed as the menstruum, less of the albuminous and mucilaginous matter is extracted, while any disadvantage from the spirituous addition is obviated by the subsequent evaporation of the alcohol and the addition of water, the provision being retained to boil the tincture for a short time to get rid of such albumen as has been taken up. Sometimes the amount of albuminous coagulum is so great as to render the process of filtration after the boiling very tedious. According to Mr. J. C. Wharton, this can be remedied by rubbing up the muddy liquid with magnesia (*A. J. P.*, xliii. 102), but to serve the same purpose precipitated calcium phosphate has been substituted in the official formula. Percolation we have found very well adapted for dissolving the sugar and producing a transparent syrup. The U. S. P. 1890 process has the merit of simplicity, but, unfortunately, the fluid extract of squill is never a wholly satisfactory preparation: if this were replaced by a corresponding quantity of vinegar of squill, reduced by evaporation if necessary, the formula would be unexceptionable.

Mr. C. A. Werckshagen proposes the following modification. Evaporate one pint of vinegar of squill to the consistence of a soft extract, to remove the acetic acid, then add eighteen fluidounces of simple syrup, and apply heat; when clear, add twenty-four grains of tartar emetic and stir until dissolved; then take off the fire and add sufficient syrup to make the whole measure twenty-two fluidounces; lastly, when cold, add two fluidounces of fluid extract of senega. If the fluid extract of senega be exactly neutralized with ammonia, no gelatinization can occur. (*A. J. P.*, 1886, p. 591.)

Compound syrup of squill combines the virtues of senega, squill, and tartar emetic, of the last of which it contains about one grain in a fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of *croup*, also in the latter stages of severe cases when the object is to promote expectoration. In croup, however, a mineral emetic is much to be preferred. The dose of this syrup is, for children, from ten drops to a fluidrachm (0·6–3·7 C.c.), according to the age, and it may be repeated in cases of croup every fifteen or twenty minutes till it vomits. As an expectorant for adults the dose is from twenty to thirty drops (1·25–1·9 C.c.).

SYRUPUS SENEGÆ. U. S. Syrup of Senega.

(SY-RŪ'PUS SĔN'Ē-GÆ.)

Sirop de Polygala, *Fr.*; Senegasyrup, *G.*

"Fluid Extract of Senega, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Ammonia Water, *five cubic centimeters* [or 81 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Fluid Extract of Senega with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water and with the Ammonia Water, and set the mixture aside for a few hours. Then filter, and pass enough Water through the filter to obtain *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims]. In the filtrate dissolve the Sugar by agitation, without heat, strain, and add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Syrup of Senega* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

The syrup affords a very convenient mode of exhibiting senega in pectoral complaints. Owing to the pectinous principle present in senega, the syrup made directly from the root as in the process of 1870 was always turbid. It has been frequently pointed out that the addition of an alkali renders the syrup transparent, and the present process directs the use of a small quantity of ammonia water, although, if the official fluid extract of senega be used, this addition should be unnecessary. This syrup may be given as a stimulant expectorant in the dose of one or two fluidrachms (3·7 or 7·5 C.c.).

SYRUPUS SENNÆ. U. S., Br. Syrup of Senna.

(SY-RŪ'PUS SĔN'NÆ.)

Sirop de Séné, *Fr.*; Sennasyrup, *G.*

"Senna (Alexandria), bruised, *two hundred and fifty grammes* [or 8 ounces av., 358 grains]; Oil of Coriander, *five cubic centimeters* [or 81 minims]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. To the Senna add *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of boiling Water, and digest, at a temperature not exceeding 60° C. (140° F.), during twenty-four hours. Then express the liquid, pass enough Water through the residue to obtain *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of liquid, and evaporate it to *four hundred cubic centimeters* [or 13 fluidounces, 250 minims]. Strain this, and, when it is cold, mix it with the Alcohol in which the Oil of Coriander had previously been dissolved. Let the precipitate subside, then pour off the clear liquid, filter the remainder, and pass enough Water through the filter to obtain *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims]. In the filtrate dissolve the Sugar by agitation, without heat, strain, and add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Senna, 40 *ounces* (Imperial) or 1200 grammes; Oil of Coriander, 10 *minims* or 0·6 cubic centimetre; Alcohol (90 per cent.), 40 *minims* or 2·4 cubic centimetres; Refined Sugar, in powder, 50 *ounces* (Imp.) or 1500 grammes; Alcohol (20 per cent.), 70 *fl. ounces* (Imp. meas.) or 2100 cubic centimetres. Moisten the Senna with *two pints* (Imp. meas.) or twelve hundred cubic centimetres of the Alcohol; pack tightly in a vessel which can afterwards be closed; set aside for three days; press strongly; reserve the liquid obtained; break up the marc; moisten it with *fifteen fluid ounces* (Imp. meas.) or four hundred and fifty cubic centimetres of the Alcohol; set aside for twenty-four hours; press strongly; add the liquid obtained to the portion previously reserved; break up the marc; mix it with the remainder of the Alcohol; set aside for three hours; press again; evaporate the resulting liquid until it is reduced to such a volume that when added to the reserved liquid the whole shall measure *two pints* (Imp. meas.) or twelve hundred cubic centimetres. Mix the evaporated liquid with the reserved liquid; heat the product in a covered vessel to 180° F. (82·2° C.) for a few minutes; set aside for twenty-four hours; filter; pass Distilled Water through the filter until the filtrate measures

forty fluid ounces (Imp. meas.) or twelve hundred cubic centimetres; add the Refined Sugar, and dissolve in a covered vessel by the aid of gentle heat; cool; add the Oil of Coriander dissolved in the Alcohol (90 per cent.); shake well. The product should weigh *five pounds twelve ounces* (Imp.) or two thousand seven hundred and sixty grammes." *Br.*

The U. S. P. 1890 syrup resembles that of the British Pharmacopœia except in the important matter of strength: it contains only one-half the quantity of senna ordered for the British syrup, and is about one-third weaker than the U. S. 1880 syrup. This is, however, not a disadvantage, as the former syrups were nearly of the strength of the fluid extract. The dose for an adult is from two to four fluidrachms (7·5–15 C.c.); but for children, for whom it was originally intended, not more than from one-eighth to one-half of that quantity, according to the age.

SYRUPUS TOLUTANUS. U. S., Br. Syrup of Tolu.

(SY-RŪ'PUS TŎL-Ū-TĀ'NŬS.)

Sirop de Baume de Tolu, Sirop balsamique, *Fr.*; Tolubalsamsyrup, *G.*

"Balsam of Tolu, *ten grammes* [or 154 grains]; Precipitated Calcium Phosphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sugar, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Alcohol, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Balsam of Tolu in the Alcohol, in a small flask or bottle, with the aid of a gentle heat. Mix the Precipitated Calcium Phosphate with *one hundred and fifty grammes* [or 5 ounces av., 127 grains] of the Sugar, in a mortar, thoroughly incorporate with it the solution of the Balsam, and set the mortar aside, in a moderately warm place, until the Alcohol has evaporated. Then triturate the residue well with *five hundred cubic centimeters* [or 16 fluidounces av., 435 minims] of Water, gradually added, and filter the mixture through a wetted filter, returning the first portions of the filtrate until it runs through clear. To the filtrate, heated to a temperature of about 60° C. (140° F.), add the remainder of the Sugar, and dissolve it by agitation. Then allow the Syrup to cool, strain it, and pass enough Water through the filter and strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly. *Syrup of Tolu* may also be made in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.**

"Balsam of Tolu, 1¼ *ounces* (Imperial) or 62·5 grammes; Refined Sugar, 2 *pounds* (Imp.) or 1600 grammes; Distilled Water, *a sufficient quantity*. Boil the Balsam of Tolu in *one pint* (Imp. meas.) or one thousand cubic centimetres of the Distilled Water for half an hour in a lightly covered vessel, stirring frequently. Then remove from the source of heat and add Distilled Water, if necessary, so that the liquid when cold shall measure *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres. Filter the solution, add the Refined Sugar, and dissolve by the aid of a water-bath. The product should weigh *three pounds* (Imp.) or two thousand four hundred grammes." *Br.*

The U. S. 1890 process for this syrup will be found more satisfactory than that formerly official. It is practically a return to the U. S. 1870 method (based on Finley's process), substituting precipitated calcium phosphate for magnesium carbonate, and improving on the latter method by using a freshly made strong tincture for the official tincture of tolu: this diminishes the quantity of alcohol left in the syrup, which had a tendency to cause the sugar to crystallize out. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter. To obviate this waste, the same portion of balsam is, according to Mr. Brande, usually employed in successive operations; and it long continues to impart odor and taste to boiling water. Mr. W. H. Hostelley's modification is as follows: For making twenty-five ounces of syrup, take one ounce of balsam of tolu, one pound of granulated sugar, and

* *Syrupus Tolutanus*, U. S. 1870. "Take of Tincture of Tolu *two fluidounces*; Carbonate of Magnesium *one hundred and twenty grains*; Sugar [refined], in coarse powder, *twenty-six troyounces*; Water *a pint*. Rub the Tincture of Tolu first with the Carbonate of Magnesium and two troyounces of the Sugar, and then with the Water, gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot."

water which has been previously filtered through animal charcoal, enough to make twenty-five ounces; rub the tolu to a fine powder, aided by some of the sugar, and mix this with the remainder of the granulated sugar; now prepare a percolator by placing a piece of cotton in the neck, pack the powder in it, pour in the filtered water, and receive twenty-five ounces of percolate. (*A. J. P.*, 1887, p. 290.) Syrup of tolu is a feeble preparation, and is used chiefly to impart its agreeable flavor to mixtures. If a stronger syrup is desired, it is readily made by adding tincture of tolu in the desired quantity and directing the bottle to be shaken.

SYRUPUS ZINGIBERIS. U. S., Br. Syrup of Ginger.

(SY-RŪ'PUS ZIN-JĬB'E-RĬS.)

Sirop de Gingembre, *Fr.;* Ingwersyrup, *G.*

"Fluid Extract of Ginger, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Precipitated Calcium Phosphate, *fifteen grammes* [or 231 grains]; Sugar, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Triturate the Fluid Extract of Ginger with the Precipitated Calcium Phosphate, and expose the mixture in a warm place until the Alcohol has evaporated. Then triturate the residue with *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Water, and filter. In the filtrate dissolve the Sugar by agitation, without heat, strain, and pass enough Water through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly *Syrup of Ginger* may also be prepared in the following manner. Prepare a percolater or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Ginger, in fine powder, ½ *ounce* (Imperial) or 12·5 grammes; Alcohol (90 per cent.), Syrup, of each *a sufficient quantity*. Prepare *one fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of a strong tincture of the Ginger by the process of percolation with the Alcohol. To this add sufficient of the Syrup to produce *twenty fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Syrup of Ginger." *Br.*

This process has been improved by the addition of precipitated calcium phosphate as an aid in distributing the resinous fluid extract so as to facilitate its solution in water. It is practically a return to the U. S. 1870 method,* magnesium carbonate being replaced by calcium phosphate, the latter being less soluble than the magnesium salt.

The British syrup, being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavor. The old plan of using water as the menstruum has been entirely abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition. In order that the preparation may be of the proper strength, it is necessary that the fluid extract should have been made with the best Jamaica ginger. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavor particularly to carbonic acid water. The dose is a fluidrachm (3·7 C.c.) or more.

TABACUM. U. S. Tobacco.

(TĂB'A-CŬM.)

"The commercial, dried leaves of Nicotiana Tabacum, Linné (nat. ord. Solanaceæ)." *U. S.*

Leaf Tobacco; Folia Nicotianæ, *P. G.;* Nicotiane, Tabac, *Fr.;* Tabak, Tabaksblätter, *G.;* Tabacco, *It.;* Tabaco, *Sp.*

Nicotiana tabacum. L. *Sp. Pl.* (1753) 180; Willd. *Sp. Plant.* i. 1014; Bigelow, *Am. Med. Bot.* ii. 171; *B. & T.* 191. The tobacco is an annual plant, with a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, and of a pale green color. The lowest are often two feet long and six inches broad. The flowers are disposed in loose terminal panicles, and are furnished with long, linear, pointed bracts at the divisions of the peduncle. The

* *Syrupus Zingiberis*, U. S. 1870. "Take of Fluid Extract of Ginger *a fluidounce;* Carbonate of Magnesium *one hundred and sixty grains;* Sugar [refined], in coarse powder, *seventy-two troyounces;* Water *forty-two fluidounces.* Rub the Fluid Extract of Ginger first with the Carbonate of Magnesium and two troyounces of the Sugar, and then with the Water, gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot."

calyx is bell-shaped, hairy, somewhat viscid, and divided at its summit into five pointed segments. The tube of the corolla is twice as long as the calyx, of a greenish hue, swelling at the top into an oblong cup, and ultimately expanding into a five-lobed, plaited, rose-colored border. The whole corolla is very viscid. The filaments incline to one side, and support oblong anthers. The pistil consists of an oval ovary, a slender style longer than the stamens, and a cleft stigma. The fruit is an ovate, two-valved, two-celled capsule, containing numerous reniform seeds, and opening at the summit. The leaves are the part employed. The seeds, examined by F. M. Brandt, yielded no narcotic principle, though a protein-like substance contained in them was thought by its decomposition to produce nicotine. (*Neues Jahrb. für Pharm.*, xxi. 42.) Prof. Procter also failed to find nicotine in the seeds. (*Proc. A. P. A.*, 1858, 296.)

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles and packed in hogsheads. While hung up in the drying-houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or, in other words, are said to sweat, after which they are dried for packing.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation; and several varieties are recognized in commerce. Other species also of Nicotiana are said to be cultivated, especially *N. rustica*, L., which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small Northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia Rivers; and *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus. The latter species is said by Mr. John Le Conte to be that from which the best Cuba tobacco is obtained.* (*A. J. P.*, 1859.) Besides these there are *N. persica*, L., cultivated in Persia; *N. repanda*, Willd., cultivated in Central and Southern North America; *N. Bigelovii*, Wats., of North America; and certain cultivated forms of *N. tabacum*, L., which have been given by some authors specific rank.

The total annual production of tobacco throughout the world at present is estimated at 5,000,000 metric centners (500,000 tons). (König, *Nahrungs- und Genussmittel*, 3e Aufl., Bd. ii.) The exportations of unmanufactured tobacco from the United States were, in 1895, 293,805,855 pounds, valued at $25,622,776; in 1896, 287,700,301 pounds, valued at $24,405,245; in 1897, 295,819,007 pounds, valued at $23,863,415.

Properties. Tobacco, as it occurs in commerce, is of a yellowish-brown color, a strong narcotic penetrating odor which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling; and the extract is, therefore, relatively feeble. Officially the leaves are described as "up to 50 Cm. [20 inches] long, oval or ovate-lanceolate, acute, entire, brown, friable, glandular-hairy, of a heavy, peculiar odor, and a nauseous, bitter, and acrid taste." *U. S.* An elaborate analysis of tobacco was made by Vauquelin, who discovered in it, among other ingredients, an acrid, volatile, colorless liquid, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco-juice with potassa. In the results of this distillation Vauquelin recognized alkaline properties, which he ascribed to ammonia, but which

* There is reason for believing that the official species is a more exclusive source of the commercial tobacco than is indicated by the text, and also in the *Pharmacographia*, where it is stated that *N. rustica* furnishes *East India Tobacco* and the kinds known as *Latakia* and *Turkish Tobacco*, *N. persica* the tobacco of Shiraz, and *N. repanda* a much valued Havana tobacco. Latakia tobacco seems, however, to be the product of the official plant, and Senator Vidal asserts that *N. repanda* is not found in Cuba, *N. tabacum* being the only species there cultivated. (*P. J. Tr.*, viii. 710.) Again, the Persian and Turkish tobacco sold under the name of *tumbeki* of commerce, which has been variously attributed to *N. persica* and to *N. rustica*, is in all probability the product of *N. tabacum*. (*Kew Bulletin*, April, 1891.)

were, in part at least, dependent upon the acrid principle above mentioned. To this principle the name of *nicotine* was given; but its alkalinity was not ascertained till a subsequent period. Another substance was obtained by Hermbstädt by simply distilling water from tobacco and allowing the liquid to stand for several days. A white crystalline matter rose to the surface, which upon being removed was found to have the odor of tobacco, and to resemble it in effects. It was fusible, volatilizable, similar to the nicotine of Vauquelin in solubility, and without alkaline or acid properties. It was called *nicotianin* by Hermbstädt, and appears to partake of the nature of volatile oils. Flückiger, who made a study of this nicotianin, is of the opinion that it is simply a fatty acid contaminated with a little volatile oil. (*Pharmacographia*, 2d ed., p. 468.) According to Landerer, it occurs only in dried tobacco-leaves. It forms white crystalline scales of a delicate tobacco-like odor, a bitter taste, and a neutral reaction. It is only slightly soluble in water, soluble in ether and alcohol. According to an analysis of Barral (*Comptes-Rendus*, 21, p. 1376), it has the formula $C_{23}H_{32}N_2O_3$. Barral states, moreover, that when distilled with strong potash solution it yields nicotine.

Two German chemists, Posselt and Reimann, subsequently analyzed tobacco, and ascertained the alkaline nature of its active principle, which, however, neither they nor Vauquelin obtained in a state of purity. According to these chemists, 10,000 parts of the fresh leaves contain 6 parts of an alkaloid, which they call *nicotine*, 1 of the *nicotianin* of Hermbstädt, 287 of slightly bitter extractive, 174 of gum mixed with a little calcium malate, 26·7 of green resin, 26 of albumen, 104·8 of a substance analogous to gluten, 51 of malic acid, 12 of ammonium malate, 4·8 of potassium sulphate, 6·3 of potassium chloride, 9·5 of potassa, which was combined in the leaves with malic and nitric acids, 16·6 of calcium phosphate, 24·2 of lime which had been combined with malic acid, 8·8 of silica, 496·9 of lignin, traces of starch, and 8828 parts of water. (Berzelius, *Traité de Chimie.*) According to M. E. Goupet, tobacco contains also a little citric acid. (*Chem. Gaz.*, Aug. 1846, p. 319.) The nicotine obtained by Vauquelin and by Posselt and Reimann was a colorless, volatile liquid, and, as subsequently ascertained by Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connection with ammonia. It was reserved for these chemists to obtain nicotine in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile.* It is easily extracted from tobacco by means of alcohol or water as a malate, from which the alkaloid can be separated by shaking it with caustic lye and ether. The ether is then expelled by warming the liquid, which finally has to be mixed with slaked lime and distilled in a stream of hydrogen, when the nicotine begins to come over at about 200° C. (392° F.). The percentage of nicotine in tobacco varies considerably,—from 1·62 per cent. in Havana tobacco and 2 per cent. in Maryland tobacco to 6 per cent. in Virginia tobacco and 8 per cent. in Kentucky tobacco. For a mode of estimating the proportion of nicotine in tobacco, see *P. J. Tr.* (Dec. 1873, 442). For an analysis of the ashes of Virginia tobacco, by Messrs. McD. Irby, of New Orleans, and J. A. Cabell, of Virginia, see *Chem. News* (Sept. 4, 1874, 117).

Nicotine. (*Nicotina* or *Nicotia.*) This is a colorless or nearly colorless fluid; of the sp. gr. 1·027; boiling at 247° C. (476·6° F.), and not solidifying at —15° C. (14° F.); of little smell when cold; of an exceedingly acrid burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapor, very irritant to the nostrils, with an odor recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction; and capable of forming crystallizable salts with the acids. These salts are deliquescent, having a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. Nicotine contains a much larger proportion of nitrogen than most of the other organic alkalies. Its formula is $C_{10}H_{14}N_2$, and it is recognized as a *hexahydrodipyridyl*, $C_{10}H_8(H_6)N_2$. While nicotine has not been prepared synthetically as yet, two isomeric bases, *isonicotine* and *nicotidine*, have been prepared. On treatment with oxidizing agents, nicotine yields *nicotinic* or *β-pyridinecarboxylic acid*, $C_5H_4N.COOH$. In its action on the animal system it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, is sufficient to destroy a dog; and small birds perish at the approach of a tube containing it. In man, it is said to destroy life, in poisonous doses, in from two to five minutes. Tannin forms with it a compound of but slight solubility, and might be employed as an antidote. It exists in tobacco in small proportion. It has been found in the seeds, and, in very small proportion, in the root. There can be little doubt that tobacco owes its activity to this alkaloid, which has also been criminally employed as a poison. (*N. Y.*

* For Liecke's and Schloesing's methods of estimating nicotine, see 17th ed. *U. S. D.*, p. 1346. For Kosutany's method, see *Zeits. f. Anal. Chem.*, 1893, 277.

Jour. of Med., N. S., ix.) Nicotine has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death. Prof. F. F. Mayer, of New York, has concluded from his experiments that nicotine is the active principle in all parts of the plant both before and after curing. (*Proc. A. P. A.*, 1865.)

Vohl and Eulenberg (*P. J. Tr.*, Jan. 1872, p. 567) made an interesting analysis of tobacco-smoke. The smoke analyzed was from strong tobacco, containing 4 per cent. of nicotine. Notwithstanding this large proportion of nicotine, none of it was found in the smoke, the authors differing in their results from most previous observers. The subject has been reinvestigated by R. Kissling (*Ding. Polyt. Journ.*, 244, 64), who has shown that Vohl's conclusion as to the non-existence of nicotine in tobacco-smoke is due to that chemist having overlooked the fact that the alkaloid is decomposed by warm caustic potash, a reaction which has not met with general recognition.

When cigars were smoked, certain gases were given off, which, when collected and examined, proved to be oxygen, nitrogen, carbonic acid, and marsh-gas. The smoke was drawn first through a potassa solution to collect acids, and then through dilute sulphuric acid to collect bases. With the potassa solution, an oily substance appeared on the surface, having an almost intolerable odor of tobacco-smoke, and from this was obtained, by distillation at a gradually increasing temperature, at first a liquid and oily product, and, at the temperature of 300° C. (572° F.), a substance which on cooling became a laminated mass. This, on being repeatedly crystallized from ether, assumed the appearance of pearly white scales, melting between 94° and 95° C. (201·2° and 203° F.), and of a higher boiling point than mercury. From these characters, as well as its percentage composition, this substance appears to be identical with the hydrocarbon ($C_{19}H_{18}$) discovered by Kraut. The oily distillate before this, having been purified by repeated treatment with potassa and sulphuric acid, had a sp. gr. 0·8 to 0·87, and from its percentage composition (92 or 93 C. and 8 or 7 H) appears to be a mixture of different hydrocarbons belonging to the benzene or some analogous series. The potassa solution, after the separation of the oils, yielded, under appropriate treatment, a large amount of gas, consisting of carbon dioxide and hydrogen cyanide and sulphide: consequently the statement that tobacco-smoke contains no cyanogen is a mistake. Upon a distillation of the potassa solution after the addition of sulphuric acid, several acids were found in the distillate,—viz., acetic, propionic, butyric, valerianic, and carbolic, with a portion of creosote, more doubtfully caproic, caprylic, and succinic acids. Only the sulphuric acid solution now remained for examination. From this, which had become dark-colored and thick on standing, a *dark-brown resin* was separated. By treatment with potassa, *ammoniacal vapors* escaped, and a *brown oil* with the odor of tobacco-smoke floated on the surface. From the residuary liquid, after distillation, saturation with caustic potassa, and redistillation, vapors escaped which proved to be *ammonium chloride*. After further treatment, for which we refer to the original, the oily residue was divided by fractional distillation, and the whole series of picoline bases, analogous to the aniline bases, were obtained. The identity of the following was determined by their boiling point, percentage composition, and the composition of the double platinum salt: *pyridine*, C_5H_5N, boiling point 115° to 116° C. (239° to 240·8° F.); *picoline*, C_6H_7N, boiling point 134° to 135° C. (273·2° to 275° F.); *lutidine*, C_7H_9N, boiling point 155° C. (311° F.); *collidine*, $C_8H_{11}N$, boiling point 171·5° C. (341° F.) (isomeric with xylidine); *parvoline*, $C_9H_{13}N$, boiling point 187° to 188° C. (368·6° to 370·4° F.) (isomeric with cumudine); *coridine*, $C_{10}H_{15}N$, boiling point 211° C. (411·8° F.); *rubidine*, $C_{11}H_{17}N$; and probably *viridine*, $C_{12}H_{19}N$, boiling point 251° C. (483·8° F.). No trace of *nicotine* was to be found. The authors experimented physiologically with only a mixture, of those boiling below 160° C. (320° F.), and of those boiling between 160° and 250° C. (320° and 482° F.); and these were found, like nicotine, to cause contraction of the pupil, dyspnœa, general convulsions, and death.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Mr. Brodie proved to be a most virulent poison. A single drop, injected into the rectum of a cat, occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark-brown color and an acrid taste, and has a very disagreeable odor, exactly resembling that of tobacco-pipes which have been much used. It has been stated to contain nicotine. (*Ann. de Chim. et de Phys.*, 3e sér., ix. 465.)

It is quite certain that tobacco-leaves undergo considerable chemical changes during the processes of curing and preparation for use. Thus, the characteristic odor of ordinary tobacco is

entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. It has also been asserted that the proportion of nicotine in prepared tobacco is greater than in the fresh. It has even been made a question whether nicotine exists at all in the fresh growing leaves; but this question has been experimentally decided in the affirmative by Prof. Procter (*Proc. A. P. A.*, 1858, p. 300); and Prof. Mayer, of New York, has experimentally determined that the nicotine exists as largely in the plant before as after curing; indeed, he believes that it is somewhat diminished in the process, probably in part if not altogether by volatilization. (*Ibid.*, 1865.)

The distinguishing character of tobacco, as given in the Br. Pharm. 1885, is that when distilled with solution of potassa it yields an alkaline fluid having the peculiar odor of nicotine and giving precipitates with platinic chloride and tincture of galls.

Medical Properties and Uses. Tobacco is a powerful sedative poison, which is locally irritant. Snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; chewed, it irritates the mucous membrane of the mouth and increases the flow of saliva; when injected into the rectum, it sometimes operates as a cathartic; and the alkaloid nicotine injected into the cellular tissue of animals evidently produces much pain. Moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general depression of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coolness of the skin, fainting, and sometimes convulsions. We are singularly deficient in exact knowledge as to how these various symptoms are produced. In accordance with the experimental evidence at hand, the convulsions are spinal; and it seems well determined that the paralysis is due to a depressant action upon the motor nerve-trunks, which immediately after death are found to be inexcitable. How the circulatory phenomena are brought about is not clear, but it would appear that the heart-muscle is not itself directly affected, as Benham found that the direct application of the poison to the viscus does not arrest its pulsations.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature, to have thus surmounted the first repugnance to its odor and taste and to have become the passion of so many millions. When employed in excess, it enfeebles digestion, produces emaciation and general debility, and lays the foundation of serious nervous disorders. The most common of these is undoubtedly disturbance of the innervation of the heart, with consequent palpitations and cardiac distress. Amaurosis and even color-blindness are occasionally produced, and even insanity has been ascribed to chronic tobacco poisoning. In many cases of "nervous break-down" attributed to overwork, the excessive use of tobacco has certainly been an important etiological factor. In the form of snuff, tobacco is sometimes so much contaminated with lead, in consequence of being kept in leaden boxes, as to produce the poisonous effects of that metal. In different kinds of snuff Dr. A. Vogel found from 0·014 to 1·025 per cent. of lead. (See *A. J. P.*, 1864, p. 422.)

Formerly much used as a relaxant, tobacco has been superseded by safer and more efficacious remedies, so that it is at present never employed in medicine, unless it be internally in *chronic asthma* and locally in *hemorrhoids* and in various spasmodic or painful affections. It should always be borne in mind that its active principle is absorbed readily by the skin, and that serious or even fatal poisoning may result from its too free application to the surface of the body. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of *tinea capitis*. Death has also been produced by the inhalation of the smoke.*

From five to six grains (0·33–0·4 Gm.) of powdered tobacco will generally act as an emetic; but the remedy ought never to be used for such purpose.

* *Enema Tabaci. Br.* 1867. *Enema of Tobacco.* This preparation, though no longer official, is still occasionally used. "Take of Leaf Tobacco *twenty grains;* Boiling Water *eight fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.* The whole quantity is to be given at once.

TABELLÆ TRINITRINI. Br. Trinitrin Tablets.

(TĂ-BĔL'LÆ TRĪ-NĪ'TRĮ-NĪ.)

Tablets of Nitroglycerin.

"Tablets of chocolate each weighing five grains (0·324 gramme) and containing one-hundredth of a grain (0·00065 gramme) of the trinitroglycerin of commerce." *Br.* Each of these tablets contains a dose of the remedy. For the properties of nitroglycerin, see *Spiritus Glonoini;* also PART II.

TAMARINDUS. U. S., Br. Tamarind.

(TĂM-Ą-RĪN'DŲS.)

"The preserved pulp of the fruit of Tamarindus Indica, Linné (nat. ord. Leguminosæ)." *U. S.* "The fruits of Tamarindus indica, Linn., freed from the brittle outer part of the pericarp and preserved with sugar." *Br.*

Pulpa Tamarindorum Cruda, s. Fructus Tamarindorum, *P. G.;* Tamarin, Tamarins, *Fr.;* Tamarinden, *G.;* Tamarindi, *It.;* Tamarindos, *Sp.*

Tamarindus indica. L. *Sp. Pl.* (1753) 180; Willd. *Sp. Plant.* iii. 577; *B. & T.* 92. The tamarind-tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-colored bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a yellowish-green color. The flowers, which are in small lateral racemes, have a yellowish calyx, and yellow petals beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-colored pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-colored acid pulpy matter, between which and the shell are several somewhat branched tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated. The tree appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some to have been imported into America. Dr. Barth, the African traveller, found it abundant in the interior of Africa. De Candolle is doubtful whether the East and West India trees are of the same species. It is stated by writers that the pods of the former are much larger than those of the latter, and have a greater number of seeds, the East India tamarinds containing six or seven, those from the West Indies rarely more than three or four; but this seems not to be correct.

Calcutta appears to be the chief emporium for the tamarinds of the European markets. Tamarinds are also sent from the West Indies and Ecuador to England; when from this source they are preferred. The latter are known as American tamarinds, and are obtained from *T. indica* (var. *occidentalis*), Gärtn. They are of a light brown color, less cohesive and possess less acidity than the tamarinds from the Old World. Tamarinds are brought to us chiefly from the West Indies, where they are prepared by placing the pods, previously deprived of their shell, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers. In the East Indies tamarinds are often prepared for market by stripping off the outer shell and pressing the pulpy interiors into a mass; sometimes they are packed as in the West Indies.

Properties. Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-colored adhesive mass, consisting of syrup mixed with the pulp, membrane, strong somewhat branching fibres or strings, and seeds of the pod, and having a sweet acidulous taste. The brown, flattish, quadrangular seeds, each enclosed in a tough membrane, should be hard, clean, and not swollen, the strings tough and entire, and the smell without mustiness. "A piece of bright iron, left for thirty minutes in contact with the pulp previously somewhat diluted with water, should not exhibit any reddish deposit of *copper*." *U. S.* From the analysis of Vauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9·40 parts of citric acid, 1·55 of tartaric acid, 0·45 of malic acid, 3·25 of potassium bitartrate, 4·70 of gum, 6·25 of jelly, 34·35 of parenchymatous matter, and 27·55 of water. K. Müller (*Pharm. Centralh.*, 1882), after analyzing nine commercial varieties, states that only traces of citric and malic acids are present, but that tartaric acid and acid potassium tartrate are present in considerable amount. It is said that copper may sometimes be detected in preserved tamarinds, derived from the boilers in which

they are occasionally prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Medical Properties and Uses. Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connection with other mild cathartics, and is one of the ingredients in the confection of senna. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power; and the same observation has been made of its influence upon the resinous cathartics in general. For a formula for *fluid extract of tamarind*, see *Nat. Drug.*, 1892, 101. From a drachm to an ounce (3·9–31·1 Gm.) or more may be taken at a dose.

TANACETUM. U.S. Tansy.

(TĂN-Ą-CĒ'TŬM.)

"The leaves and tops of Tanacetum vulgare, Linné (nat. ord. Compositæ)." *U. S.*

Summitates Tanaceti; Herbe aux Vers, Tanaisie, *Fr.;* Gemeiner Rainfarn, Wurmkraut, *G.;* Tanaceto, *It., Sp.*

Tanacetum vulgare. L. *Sp. Pl.* (1753) 844; Willd. *Sp. Plant.* iii. 1814; Woodv. *Med. Bot.* 66, t. 27. This is a perennial herbaceous plant, rising two or three feet in height. The stems are strong, erect, obscurely hexagonal, striated, often reddish, branched towards the summit, and furnished with alternate, doubly pinnatifid leaves, the divisions of which are notched or deeply serrate. The flowers are yellow, and in dense terminal corymbs. Each flower is composed of numerous florets, of which those constituting the disk are perfect and five-cleft, those of the ray very few, pistillate, and trifid. The calyx consists of small, imbricated, lanceolate leaflets, having a dry scaly margin. The achenes are small, oblong, with five or six ribs, and crowned with a membranous pappus.

Tansy is cultivated in our gardens, and grows wild in the roads and in old fields, but was introduced from Europe, where it is indigenous. It is in flower from July to September. There is a variety of the plant with curled leaves, which is said to be more grateful to the stomach than that above described, but has less of the peculiar sensible properties of the herb, and is probably less active.

Properties. "Leaves about 15 Cm. [six inches] long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark green, and glandular; flower-heads corymbose, with an imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets." *U. S.* The odor is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. According to Leppig (*Inaug. Diss.*, Dorpat, 1882), both the flowers and the leaves contain the following constituents: *tanacetin*, tannic acid (*tanacetum-tannic acid*), traces of gallic acid, volatile oil, a wax-like substance, albuminoids, tartaric, citric, and malic acids, traces of oxalic acid, a lævogyrate sugar, resin, metarabic acid, pararabin, and woody fibre. Of these the most important are the bitter principle *tanacetin*, to which Leppig gives the formula $C_{11}H_{16}O_4$, a compound first discovered by Homolle (1845), the tannic acid, to which he gives the formula $C_{23}H_{29}O_{31}$, and the volatile oil, of which the flowers yielded 1·49 per cent. and the leaves 0·66 per cent. The *tanacetic acid* of Peschier he considers to be impure malic acid, an opinion shared by Husemann. (*Pflanzenstoffe*, 2d ed., 1884, p. 1531.) The bitter principle tanacetin forms a very hygroscopic brownish amorphous mass, easily soluble in alcohol and in water, insoluble in ether. It possesses a taste at first characteristically bitter like willow bark, and then cooling and caustic. The essential oil was investigated by Bruylants (*Ber. der Chem. Ges.*, xi. 449), who found it to consist of a terpene, $C_{10}H_{16}$, boiling at from 155°–160° C., of which 1 per cent. only is present, an aldehyde, $C_{10}H_{16}O$, boiling at from 195°–196° C., of which 70 per cent. was obtained, and an alcohol (borneol), $C_{10}H_{18}O$, boiling at from 203°–205° C., of which 26 per cent. was present. Semmler (*Ber. der Chem. Ges.*, xxv. 3343, 3352, 3513) has specially investigated the constituent boiling at 195° C. and having the composition $C_{10}H_{16}O$. He finds it to be not an aldehyde, but a ketone, and calls it *tanacetone*. It is identical with the ketone found in sage oil, wormwood oil, and thuja oil. As it was first identified in this last-named oil by Wallach, and named by him *thujone*, this name is now applied to it to the exclusion of the other. (See also *Schimmel's Reports*, April, 1893, 63 and 64, and April, 1897, 46 and 47.)

Medical Properties and Uses. Tansy adds to the medical properties of the aromatic bitters those of an irritant narcotic. It has been recommended in *intermittents*, *hysteria*, and *amenorrhœa*, but in this country is little employed in regular practice. The seeds are said to

be most effectual as a vermifuge. The dose of the powder is from thirty grains to a drachm (1·95–3·9 Gm.) two or three times a day; but the infusion is more frequently administered. Tansy has been used to a considerable extent as a domestic abortifacient, but is not only very uncertain but also very dangerous in its action, and has in various cases produced death. The symptoms caused by it have been abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which has been said to be from heart-failure, but is probably the outcome of a paralytic asphyxia. The minimum fatal dose can scarcely be considered to have been positively ascertained, but a drachm of the oil is said to have caused death, though half an ounce has been recovered from. Tansy tea has also caused death. (For cases, see *Amer. Jour. Med. Sci.*, xvi., xxiii., xxiv.; *Journ. de Pharm.*, Avril, 1870; also H. C. Wood's *Therapeutics.*) Post-mortems have been reported in which no inflammation of the gastro-intestinal mucous membranes could be discovered.

TARAXACUM. U.S. (Br.) Taraxacum. [Dandelion.]

(TĂ-RĂX'Ă-CŬM.)

"The root of Taraxacum officinale, Weber (nat. ord. Compositæ), gathered in autumn." *U. S.* "The fresh and the dried roots of Taraxacum officinale, Wiggers. Collected in the autumn." *Br.*

Taraxaci Radix, *Br.;* Dandelion Root; Pissenlit, Dent de Lion, *Fr.;* Löwenzahn, *G.;* Tarassaco, *It.;* Diente de Leon, *Sp.*

Taraxacum taraxacum (L.). Karst. *Deutsch Fl.* (1880–83).—*Leontodon taraxacum.* L. *Sp. Pl.* (1753).—*T. officinale.* Weber, *Prim. Pl. Holst.* (1780).—*T. dens-leonis.* Desf. *Fl. Atlant.* (1800). The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green color. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-colored flower, which closes in the evening and expands with the returning light of the sun. The calyx is smooth and double, with the outer scales bent downward. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is flat and naked. The pappus is stipitate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the achene attached. Another plant resembling the common dandelion, the achenes of which, however, are narrower and bright red or reddish brown, known as the *red-seeded dandelion*, is the product of *T. erythrospermum*, Andrz., and is supposed by some to be naturalized from Europe.

Section of Taraxacum root. (After Berg.)

This species of Taraxacum grows spontaneously in widely separated parts of the globe. It is abundant in this country, adorning our grass-plats and pasture-grounds with its bright yellow flowers, which, in moist places, show themselves with the first opening of spring and continue to appear till near the close of summer. In India the plant is cultivated in various parts of the country, and its root collected for use between the months of September and February. (*P. J. Tr.*, Dec. 1871, 523.) All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and are sometimes used as a salad. When older and of their natural color, they are medicinal. The Pharmacopœias recognize only the root, which is by far the most efficacious part. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness

by drying; and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn; and sweet and less bitter in the winter when affected by the frost. The months of July, August, and September are, therefore, the proper periods for collecting it.

Mr. Henry Barton, of Brighton, England, prepares the juice from the flower-stalks by crushing and pressure, adding 25 per cent. of spirit, and, after allowing it to stand for some weeks in glass bottles, filters to separate a very small quantity of deposit, and sets aside for use. According to Mr. Barton, it remains bright, and retains its characteristic taste. Though not so rich in solid constituents as the juice of the root, yet, having an equal bitterness, it is probably not less efficacious as a medicine, if it be true, as stated by Prof. Bentley, that the efficacy of the medicine does not depend solely on the amount of its solid constituents, but principally if not entirely on the bitter principle it contains. Mr. Barton states that it is certainly one of the best preparations of taraxacum. (*A. J. P.*, 1872, p. 509.)

The fresh full-grown root of the dandelion is several inches in length, as thick as the little finger or thicker, round and tapering, somewhat branched, of a light brown color externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is dark brown, much shrunk, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. A transverse section exhibits an exterior cortical portion, thick, spongy, whitish, and marked with concentric rings, and a smaller central portion, ligneous and yellow; though in very old roots the latter is sometimes wanting. It is without smell, but has a sweetish, mucilaginous, bitterish, herbaceous taste. It should be free from the root of *Cichorium intybus* (Linné), which closely resembles it, but is usually paler, more bitter, and has the milk-vessels in radiating lines. Contrary to the general statement, that taraxacum root contains a central wood-cylinder without any pith, Prof. Jos. Schrenk states that he has found a distinct pith in a very large number of roots taken from commercial samples of taraxacum. From ten to fifteen fibro-vascular bundles surrounded by parenchyma-tissue include the pith, the diameter of which in some instances exceeds the thickness of the woody zone several times. In other respects the structure of the root was normal, the concentric arrangement of the laticiferous ducts in particular excluding any possibility of mistaking the specimens for chicory, etc. (*Amer. Drug.*, 1887, p. 2.) Its active properties are yielded to water by boiling, and do not appear to be injured in the process. Dragendorff obtained from the root gathered in October and dried at 100° C. (212° F.) 24 per cent. of *inulin* and some sugar. The root gathered in March from the same place yielded 1·74 per cent. of inulin, 17 of uncrystallizable sugar, and 18·7 of *levulin*. This last-named substance, discovered by Dragendorff, has the same composition as inulin, but dissolves in cold water, and is devoid of any rotatory power. Mannite, which has been found in the infusion of the root, has been demonstrated by the Messrs. Smith, of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure. A crystallizable principle has been extracted from the juice of the root by M. Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. Kromayer (*Arch. d. Pharm.* (2), cv. 6) also obtained taraxacin, and, in addition, a second crystalline principle, *taraxacerin*, $C_8H_{16}O$, insoluble in water, but soluble in alcohol. According to Vogel, the intra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. Prof. L. E. Sayre found that the yield of taraxacin varies in roots collected at different seasons. (See *Proc. A. P. A.*, 1893, 1894, 1895, 1896, 1897.)

The roots of various plants have been largely substituted for dandelion in England and on the Continent by the herb-gatherers; and we are informed that fraudulent substitution is not unfrequent, in this country, of the root of *Cichorium intybus*, or *chicory*. It is rare to find chicory mixed with dandelion, the former being usually boldly substituted for the latter.

Medical Properties and Uses. Taraxacum is slightly tonic, diuretic, and aperient, and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Germany, and is a popular remedy with many practitioners in this country. The diseases to which it appears to be espe-

cially applicable are those connected with derangement of the hepatic apparatus and of the digestive organs generally. Professor George B. Wood had confidence in it in the treatment of *chronic congestion* and *inflammation of the liver and spleen*, provided that there was no irritation or inflammation of the gastro-intestinal mucous membrane. He was accustomed to combine with it potassium bitartrate and aromatics when an aperient effect was desired. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is also used as a substitute for coffee, being powdered and roasted and then prepared in the same manner.

TEREBENUM. U. S., Br. Terebene.

$C_{10}H_{16}$; 135·7. (TĔR-Ē-BĒ'NŬM.)

"A liquid consisting chiefly of Pinene, and containing not more than very small proportions of Terpinene and Dipentene. Terebene should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.* "A mixture of dipentene and other hydrocarbons, obtained by agitating oil of turpentine with successive quantities of sulphuric acid until it no longer rotates the plane of a ray of polarized light, and then distilling in a current of steam." *Br.*

This is a substance which is produced by the action of sulphuric acid upon oil of turpentine. The sulphuric acid must be added gradually to the cooled oil of turpentine, in the proportion of one part of acid to twenty parts of oil, and after a day's standing the mixture is heated to boiling. After cooling, the oily layer is removed, freed from acid by calcium carbonate, and rectified. The terebene so obtained boils at 156° C., is optically inactive and of rather pleasant odor. Some cymol is always produced at the same time, and by continued action of the acid the terebene is said to be entirely converted into cymol and colophene. Jayne and Chase, however, from a study of a number of samples of commercial terebenes (*A. J. P.*, 1887, p. 65), conclude that the boiling point of the true terebene is much higher, 173°–180° C. They found an inactive camphor, boiling at about 200° C. (probably *borneol*), to be formed also, and the residue left on rectifying was principally *colophene*. Terebene is officially described as "a colorless or slightly yellowish, thin liquid, having a rather agreeable, thyme-like odor, and an aromatic, somewhat terebinthinate taste. Specific gravity, about 0·862 at 15° C. (59° F.). Only slightly soluble in water, but soluble in an equal volume of alcohol, glacial acetic acid, or carbon disulphide. It boils at 156° to 160° C. (312·8° to 320° F.). On exposure to light and air, Terebene gradually becomes resinified, and acquires an acid reaction. In its chemical properties it resembles oil of turpentine. Terebene should possess its characteristic agreeable odor, should not redden moistened blue litmus paper (absence of *acids*), and should not have more than a very slight action on polarized light (limit of *unaltered oil of turpentine*). When evaporated, it should not leave more than a very slight residue (absence of more than traces of *resinous matters*)." *U. S.* "A colorless liquid, having an agreeable odor and an aromatic terebinthinate taste. Specific gravity 0·862 to 0·866. Does not rotate the plane of a ray of polarized light. Should distil between 312·8° and 356° F. (156° and 180° C.), leaving only a slight viscid residue (absence of excess of resin). Not more than 15 per cent. should distil below 329° F. (165° C.)." *Br.* Power and Kleber (*Pharm. Rund.*, 1894, 18) state that pinene is not obtained by the action of sulphuric acid on oil of turpentine, that the U. S. P. boiling points 156°–160° C. should be 170°–185° C., and that the sp. gr. should be 0·855 instead of 0·862; also that terebene consists mainly of *dipentene* and *terpinene* with some cymol and camphene.

Medical Properties and Uses. Terebene is a valuable stimulant expectorant, first recommended by Dr. William Murrell (*Brit. Med. Journ.*, Dec. 1885), in that form of *chronic bronchitis* often known as winter cough. It is very useful not only in cases of chronic bronchitis, but also in the *acute* disease, after the earlier stages have passed by. It is nearly equivalent to the oil of eucalyptus, but is a little more stimulating. It probably exerts upon other mucous membrane the same action that it does upon that of the lungs, and it has been employed with asserted good results in *dyspepsia*, especially in the flatulent intestinal variety, and may be used in chronic or subacute inflammation of the genito-urinary tract. Its action upon the general system has not been investigated, but probably resembles that of oil of turpentine. It may be given in emulsion, or, preferably, in capsules. From twenty to sixty minims (1·2–3·7 C.c.) of it may be given to the adult in the course of twenty-four hours, and increased, if necessary. It has also been used by atomization, with asserted good results. Dr.

Murrell (*Brit. Med. Journ.*, July 24, 1884) states that terebene is an active antiseptic and germicide, one part in four hundred and fifty being able to keep in check the action of the yeast plant, and one part in five hundred having a very perceptible influence on the development of bacilli and paramœcia.

TEREBINTHINA. U. S. (Br.) Turpentine.

(TĔR-Ę-BĬN'THI-NĄ.)

"A concrete oleoresin obtained from Pinus palustris, Miller, and from other species of Pinus (nat. ord. Coniferæ)." *U. S.* "The concrete oleoresin which is scraped off the trunks of Pinus palustris, Mill., and Pinus Tæda, Linn." *Br.*

TEREBINTHINA CANADENSIS. U. S., Br. Canada Turpentine.

[Canada Balsam, Balsam of Fir.]

(TĔR-Ę-BĬN'THI-NĄ CĂN-Ą-DĔN-SIS.)

"A liquid oleoresin obtained from Abies balsamea (Linné), Miller (nat. ord. Coniferæ)." *U. S.* "The oleoresin obtained from Abies balsamea, Mill." *Br.*

Balsamum Canadense; **Térébenthine de Canada, Baume de Canada, Térébenthine**, *Fr.*; **Terpentin, Canadischer Terpentin**, *G.*; **Trementina**, *It., Sp.*

The term *turpentine* is usually applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called *oil of turpentine*. They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as, for instance, *Pistacia terebinthus*, which yields the Chian turpentine. Some French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, etc. We shall describe particularly, in this place, the turpentines which are either now official or have but recently ceased to be so. A brief botanical view of the plants from which they are respectively derived will be in accordance with the plan of this work. It is proper to observe first that the nat. ord. Coniferæ includes about three hundred and fifty species. These may be divided into two sub-orders, as Engler and Prantl suggest,—viz., *Pinoideæ* and *Taxoideæ*. Lindley had previously recommended a similar subdivision, but considered each sub-group as deserving of family rank, and gave them the names Pinaceæ and Taxaceæ. Britton and Brown, in their *Illustrated Flora of the U. S. and Canada*, follow Lindley in this instance. The *Pinoideæ* may be further subdivided into the (A) *Abietineæ*, including Araucaria, Pinus, Cedrus, Larix, Picea, Tsuga, Abies, Sequoia, Taxodium, etc.; and (B) *Cupressineæ*, which includes Thuja, Juniperus, etc. The *Taxoideæ* includes Ginkgo, Taxus, etc.

The genus Pinus is represented by about seventy species, which are widely distributed throughout the northern hemispheres of both continents. The principal centres of distribution of the species of this genus are in the Western United States (twenty-one species), Eastern United States (thirteen species), and the highlands of Mexico. It is one of the most important genera from an economical stand-point. . The following species yield valuable timber: *P. palustris*, *P. strobus*, *P. echinata*, *P. lambertiana*, *P. ponderosa*, *P. monticola*, *P. heterophylla*, *P. sylvestris*, *P. laricio*, *P. nepalensis*, *P. thunbergii*, and *P. densiflora*. Turpentine is obtained chiefly from the Eastern American *P. palustris* and *P. heterophylla;* it is also obtained from *P. pinaster* and *P. halepensis* of the Mediterranean basin, and from the Himalayan *P. roxburghii*. The edible seeds (*Pine Nuts*) of several species yield important articles of human food, the best being produced by the nut pines of Western North America, by *P. pinea* of the Mediterranean, *P. cembra* of Europe and Asia, and *P. gerardiana* of Northwestern India. *Pine wool*, a coarse fibre manufactured from the leaves of *P. laricio*, *P. sylvestris*, and other European species, is used to stuff mattresses and cushions, and, woven with animal wool, is made into hospital and military blankets and into underclothing which are reputed to possess medical properties. In the Southern United States carpets are woven from the leaves of *P. palustris*. The bark of several species contains sufficient tannin to make them valuable for tanning leather.

1. *Pinus palustris*. Mill. *Gard. Dict.* (1768) 8th ed., No. 14.—*P. australis*. Michx. f. *Hist. Arb. Am.* (1810) i. 64. Leaves in threes, from ten to fifteen inches long, subtended at the

base by a conspicuous scaly sheath from one to one and a half inches long. The leaves are crowded at the ends of the branches. The cones are terminal, conical, and armed with a short recurved spine.

This is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green color, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are *long-leaved pine*, *yellow pine*, *Southern pine*, *hard pine*, *Virginia pine*, and *pitch pine;* but the first is the most appropriate. This tree furnishes by far the greater proportion of the turpentine, tar, etc., consumed in or exported from the United States. (See *Pix Liquida.*)

2. *Pinus tæda.* L. *Sp. Pl.* (1753) 1000; Willd. *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylva*, iii. 156; *B. & T.* 259. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

This is the *loblolly* or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are about six inches long, and of a light green color. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3. *Pinus sylvestris.* L. *Sp. Pl.* (1753) 1000; Willd. *Sp. Plant.* iv. 494; Michaux, *N. Am. Sylva*, iii. 125; *B. & T.* 257. Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales linear-oblong, the ends much thickened, their exposed parts (apophysis) oblique, rhomboidal, with a transverse ridge and central tubercle.

This tree, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits the northern and mountainous parts of Europe. In Great Britain it is called the *wild pine* or *Scotch fir*, the latter name being due to its abundance on the mountains of Scotland. It yields a considerable proportion of the common European turpentine.

Pinus pumilio. Haenke, Jviasek, *Beob. Riesengeb.* (1791) 68.—*P. montana.* Mill. *Gard. Dict.*, 8th ed., No. 5. This pine is known in gardens under several names which are given to the forms occurring in the different mountain ranges over which it is spread. Beissner, in his *Handbuch der Nadelholzkunde*, considers *P. pumilio*, Haenke, a synonym of *P. montana*, Mill.; whereas in the *Index Kewensis* the latter is brought under the former. Most authors agree with De Candolle and Beissner in bringing *P. pumilio*, Haenke, under *P. montana*, Mill. The latter is a small tree, with decumbent or knee-like more or less erect branches, which are covered with a dark-colored persistent bark. The leaves occur two in a sheath, each of which is from two to five Cm. long, straight, or scythe-shaped, with obtuse apex; both sides are dull green and slightly glaucous. The cones are ovoid, about one and a half inches long, with a pyramidal protuberance on each scale on the outer or exposed side. It is found in the subalpine regions of Central Europe at elevations between 1300 and 2500 metres; also on the Carpathian Mountains at from 1300 to 1800 metres. From the branches a terebinthinate juice exudes spontaneously, called *Hungarian balsam*. *Pinus maritima* (*P. pinaster* of Aiton and Lambert), growing in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the official plants in the French Codex. *Pinus lambertiana*, of California, produces by exudation a saccharine matter which has been found to contain a peculiar sweet principle called *pinit.* (*Comptes-Rendus*, Sept. 1855.) *Pinus sabiniana*, Dougl., known as *nut-pine* or *digger-pine* (because the nut is largely consumed by the Digger Indians), yields, on being notched, a terebinthinate exudation, which is largely distilled for the sake of its volatile oil, extensively used in California under the name of *abietene* * and other less appropriate designations. The *Pinus rigida*, or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar.

ABIES. The genus Abies is represented by about twenty-three species, which are distributed in the New World from Labrador and the valley of the Athabasca River to the mountains of North Carolina and from the mountains of Alaska to the highlands of Guatemala, and in the Old World from Siberia and the mountains of Central Europe to Southern Japan, the

* Commercial abietene resembles in appearance commercial oil of turpentine, but has a peculiar orange-like fragrance and a mild terebinthinate taste, probably due to traces in it of resin or other impurity. Its appearance suggests that its medical properties are similar to those of turpentine, but (see PART I., p. 971) its chemical constituent is practically identical with that of petroleum oil of about 150° fire-test.

Himalayas, Asia Minor, and the mountains of Northern Africa. The species of this genus yield soft, perishable woods and balsamic exudations, which are employed in medicine and the arts.

Abies balsamea. Mill. *Gard. Dict.* (1768) 8th ed. No. 3; Lindley, *Flor. Med.* 554.—*A. balsamifera.* Michaux, *N. Am. Sylva*, iii. 191.—*Pinus balsamea.* L. *Sp. Pl.* (1753) 1002; Willd. *Sp. Plant.* iv. 504. "Leaves solitary, flat, emarginate or entire, glaucose beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bracts abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir*, or *balm of Gilead tree*, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions farther south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height and form an almost perfect pyramid. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish color, and covered with a resinous exudation, which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

Several other species of Abies are official. *Abies excelsa* of Europe and *A. canadensis* of the United States have already been described as the sources respectively of Burgundy and Canada pitch. (See *Pix Burgundica* and *Pix Canadensis.*) The *A. picea* (*Abies pectinata* of De Candolle, *A. taxifolia* of the French Codex, *Pinus picea* of Linnæus), or *European silver fir*, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strasburg turpentine*, which is much used in some parts of Europe. By the distillation of its cones with water it also affords a variety of oil of turpentine called in France *essence de terpline.* By boiling the young branches of the *Abies nigra* (*Pinus nigra*), or *black spruce* of this country, and evaporating the decoction, the *essence of spruce* is prepared. It is a thick molasses-like liquid, with a bitterish, acidulous, astringent taste, and is used for making *spruce beer.**

Abies Fraseri, Lindley. This species, commonly called *double fir*, occurs at high elevations in the mountains of Tennessee and North Carolina. The tree is noted for its hardiness, and is used for ornamental purposes. It is also said to have been used to furnish a balsam of fir similar to that obtained from *A. balsamea*, but the data concerning this are obscure.

LARIX. The genus Larix has eight recognized species, which are now widely distributed over the subarctic and mountainous regions of the northern hemisphere, ranging from the Arctic Circle to the mountains of Pennsylvania in the New World and to latitude 30° in the Old World. The species produce hard, durable, valuable timber; turpentine, which is sometimes used in medicine; tar; bark rich in tannin; and a peculiar manna-like substance.

Pinus larix. L. *Sp. Pl.* (1753) 1001; Willd. *Sp. Plant.* iv. 503; Woodv. *Med. Bot.* 7, t. 4. —*Larix europæa.* De Cand. *Flor. Fr.* 2064.—*Abies larix.* Lamb. *Illust.* t. 785, f. 2. "Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bracts panduriform."

The *European larch* is a large tree, inhabiting the mountains of Siberia, Switzerland, Germany, and the east of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance called in France *Briançon manna*, which exudes spontaneously and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes and is called *Orenburg gum.* It is wholly soluble in water.†

* The following is the formula. Take of essence of spruce *half a pint;* pimenta bruised, ginger bruised, hops, each, *four ounces;* water *three gallons.* Boil for five or ten minutes; then strain, and add of warm water *eleven gallons;* yeast *a pint;* molasses *six pints.* Mix, and allow the mixture to ferment for twenty-four hours.

† *Coniferin.* This name has been given to a principle discovered by M. Hartig in the cambium of several of the Coniferæ. The species in which it has been found are *Pinus strobus* and *P. cembra*, *Abies excelsa* and *A. pectinata*, and *Larix europæa;* and it probably exists in many others. It is obtained by removing the outer bark, scraping the cambium from the surface of the wood, subjecting this to pressure, boiling the viscid juice to coagulate the albumen, filtering, and evaporating the filtered liquid to one-fifth of its volume. The coniferin is deposited in crystals. The mother-water is very sweet, and contains a saccharine substance closely allied to cane sugar. The crystals are purified by dissolving them in water, decolorizing by animal charcoal, and finally crystallizing from weak alcohol. Coniferin was chemically examined by M. W. Kubel, and later by Tiemann and Haarmann, who proved that it is a glucoside and as crystallized from the juice has the composition $C_{16}H_{22}O_8 + 2H_2O$. When treated with dilute acids or ferments it is decomposed as follows: $C_{16}H_{22}O_8 + H_2O = C_6H_{12}O_6 + C_{10}H_{12}O_3$. When this latter compound is oxidized (or coniferin itself) by bichromate of potassium and sulphuric acid, *vanillin* is obtained, $C_6H_3(OH)\begin{cases}OCH_3\\CHO\end{cases}$. Vanillin has been thus made commercially, but is now made preferably from the eugenol of oil of cloves or from benzoin.

In Japan, the exudation from the *Pinus densiflora* and that from the *Pinus thunbergii* are used under the respective names of *akamatsu* and *kuromatsu*. They are said to contain about 18 per cent. of oil and 81 per cent. of resin. The distilled oil is bright and colorless, having an odor somewhat different from that of the European oil of turpentine. It boils at from 155° to 156° C., and has a specific gravity of a little under 0·87. Its index of polarization is from 55° to 61° (right). The resin cannot be distinguished from the European. A turpentine closely resembling the French oil is produced in Burmah from the *Pinus khasya* and *Pinus merkusii*. For details, see *P. J. Tr.*, lvi., 1896, 370.

PISTACIA. See *Mastiche.*

Pistacia terebinthus. L. *Sp. Pl.* (1753) 1025; Willd. *Sp. Plant.* iv. 752; Woodv. *Med. Bot.* 29, t. 12. This is a small tree of the nat. ord. Anacardiaceæ, with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diœcious, small, and in branching racemes. It is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the *Chian turpentine* obtained from the tree. A gall produced upon this plant by the puncture of an insect has been used in Eastern Europe in pectoral affections.

We shall treat of the several varieties of turpentine under distinct heads.

1. WHITE TURPENTINE.

Terebinthina, *U. S.;* Thus Americanum, *Br.;* Common Frankincense; Térébenthine de Boston, *Fr.*

In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union have long been entirely exhausted, and our commerce has been until recently almost exclusively supplied from North Carolina and the southeastern parts of Virginia. Within a few years, however, attention has been turned to the collection of this valuable product in Georgia and Florida; and there is no doubt that, in time, an abundant supply will be derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico. During the winter, deep notches or excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground, and for about three feet above these so-called "boxes" the tree is deprived of its bark and some of the wood scraped off. Into these the juice or "crude" begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumn, the tree being scraped every eight or ten days to prevent clogging. The liquid is removed from the "boxes" as they fill, and transferred into casks, where, if left, it gradually thickens, and ultimately acquires a soft solid consistence; but most of it is separated at once by distillation into the rosin and the volatile oil.

White turpentine, as found in commerce, is yellowish white, of a peculiar somewhat aromatic odor, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer it is almost semi-fluid and very adhesive, though brittle; in the winter it is often so firm and hard as to be incapable of being made into pills without heat. "In yellowish, opaque, tough masses, brittle in the cold, crumbly-crystalline in the interior, of a terebinthinate odor and taste. The alcoholic solution has an acid reaction." *U. S.* Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about 17 per cent. of volatile oil. It is apt to contain small pieces of bark, wood, or other impurity.

2. COMMON EUROPEAN TURPENTINE.

Térébenthine de Bordeaux, Térébenthine commune, *Fr.;* Gemeiner Terpentin, *G.;* Trementina commune, *It.;* Trementina comun, *Sp.*

This is the *Terebinthina vulgaris* of the former London Pharmacopœia. It is furnished by several species of pine, but chiefly by *P. sylvestris* and *P. maritima*. From the latter tree it is obtained largely in the maritime districts of the southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine.* It is procured by making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like that of thickened honey. As

found in European commerce, it often consists wholly of this latter portion. It speedily hardens on exposure in thin layers to the air. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two parts of the turpentine. (*Journ. de Pharm.*, xxv. 499.) It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and resin. We do not import it into this country. The substance which the French call *galipot*, or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (*Thénard.*) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch.* When turpentine, whether the European or the American, has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of Colophon, where it was formerly prepared. It is the official resin (*resina*), and is sometimes called yellow resin (*resina flava*). White resin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. (See *Resina.*) Tar (*pix liquida*) is the turpentine extracted from the wood by slow combustion and chemically altered by heat. Common pitch (*pix nigra*, or *resina nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. Canada Turpentine.

Baume de Canada, *Fr.;* Canadischer Balsam, Canadischer Terpentin, *G.;* Trementina del Canada, *It.*

Terebinthina Canadensis, U. S., Br., is collected in Canada and the State of Maine from the *Abies balsamea*, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. "A yellowish or faintly greenish, transparent, viscid liquid, of an agreeable, terebinthinate odor, and a bitterish, slightly acrid taste. When exposed to the air, it gradually dries, forming a transparent mass. It is completely soluble in ether, chloroform, or benzol." *U. S.* "Solidifying when mixed with about a sixth of its weight of *magnesia* moistened with a little *water*." *Br.* For a paper on its miscibility in alcohol, by J. E. Morrison, see *Proc. A. P. A.*, 1894, 309. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles under the name of *Canada balsam*, or *balsam of fir.* Under the microscope the hard balsam is found to be entirely free from any granular or crystalline structure. In Europe it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it, as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine 18·6 parts of volatile oil, 40·0 of resin easily dissolved by alcohol, 33·4 of sub-resin of difficult solubility in that fluid, 4·0 of caoutchouc similar to sub-resin, and 4·9 of bitter extractive and salts, besides traces of acetic acid. Flückiger found in 100 parts 24 parts of an essential oil, $C_{10}H_{16}$, with a very small proportion of an oxygenated oil, 60 parts of a resin soluble in boiling alcohol, and 16 parts of a resin soluble only in ether. (*Pharmacographia*, 2d ed., 614.) Emmerich obtained by fractional distillation of the oil *bornyl* or *terpinyl acetate*, *pinene*, and a fragrant liquid resembling oil of lemon. (*A. J. P.*, 1895, 135. See also a paper by Hunkel, *A. J. P.*, 1895, 9.) The chief distinction between it and *Strasburg turpentine*, which is sometimes sold for it in commerce, is in the diverse odors.

4. Venice Turpentine.

Térébenthine de Mélèze, Térébenthine de Venise, *Fr.;* Venetianischer Terpentin, *G.;* Trementina di Venezia, *It.;* Trementina de Venecia, *Sp.*

This turpentine was named from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and in the French province of Dauphiny, from the *Larix europæa*, or larch, which grows abundantly upon the Alps and the Jura Mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid liquid, of the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, yellowish or slightly greenish, of a strong not disagreeable odor, and a warm, bitterish, and acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *Journ. de Pharm.*, xxv. 500.) H. Beckurts and W. Brueche found the specific gravity at 15° C. from 1·060 to 1·190; acid number from 76 to 101 (Kremel found from 68 to 70·3); ester number from nothing to 6; saponification number from 81 to 101; and the iodine number from 137 to 149. (*Archiv d. Pharm.*, 1892,

ccxxx. 83.) It yields on an average 15 per cent. of essential oil, of the composition $C_{10}H_{16}$, which has been found to be nearly pure *pinene*. The residual resin is soluble in two parts of warm alcohol of 75 per cent., and more copiously in absolute alcohol. What is sold under the name of Venice turpentine, in commerce, is usually quite brown, and is a factitious substance, prepared by dissolving rosin in oil of turpentine. Dr. A. T. Thomson states that much of the Venice turpentine of London commerce is obtained from America. It is probably the same preparation as that which passes under the name in this country.

5. Chian Turpentine.

Térébenthine de Chio, *Fr.;* **Cyprischer Terpentin,** *G.;* **Trementina Cipria,** *It.*

This variety of turpentine is collected chiefly in the island of Chio, or Scio, from the *Pistacia terebinthus*, and it is said that the whole annual product of the island is only about two hundred and twenty-four pounds. During the summer the juice flowing spontaneously, or from incisions in the bark, falls upon smooth stones, or bundles of twigs, placed at the foot of the tree, from which it is procured by boiling and straining. After straining it is again boiled with a little water until all the water is evaporated, when it is finally poured into a vessel of cold water and kneaded. At first it is of a dirty yellow color, but after kneading it becomes quite white. (*P. J. Tr.*, xvi. 385.) The annual product of each tree is very small; and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow color, or it occurs as a viscid opaque mass. The odor* is peculiar, penetrating, and more agreeable than that of the other substances of the same class. The taste is mild, without bitterness or acrimony. Flückiger found nearly 14½ per cent. of essential oil, which contained a small quantity of an oxygenated oil. It leaves a glutinous residue when treated with strong alcohol. (*Guibourt.*) Its alcoholic solution does not redden litmus paper. (*Martindale.*) On exposure, liquid Chian turpentine speedily thickens, and ultimately concretes into a translucent solid, yellowish or yellowish-brown when in small pieces, greenish-brown in mass.

Besides the turpentines mentioned, various others are noticed in books on Materia Medica, though not found in commerce in this country. There are the *Strasburg turpentine*, much used in France, and obtained from the *Abies picea* (*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany and bears a close resemblance, as well in its appearance as in its product, to *Abies balsamea* of Canada; the *Russian turpentine*, from *Pinus sylvestris*;† the *Damarra turpentine*, which speedily concretes into a very hard resin, and is derived from the *Pinus damarra* of Lambert, the *Agathis damarra* of Richard, growing in the East India islands; the *cowrie* or *cowdie* resin, procured by incision from another species of Damarra (*D. australis*), in New Zealand; and the *Dombeya turpentine*, a glutinous, milky-looking fluid, of a strong odor and taste, derived from *Dombeya excelsa*, the *Araucaria dombeyi* of Richard, which inhabits Chili, and is said to be identical with the Norfolk Island pine. These, with one or two other turpentines scarcely known, or having a doubtful claim to the title, are all that belong properly to this class of vegetable products, although their numbers are continually being increased.

General Properties. The turpentines resemble one another in odor and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature

* The odor of Chian turpentine is variously described. As the only tests we now have of the purity of the drug are its physical characteristics, and of these the odor is the most important, we give the following description by Mr. Wm. Martindale. (*P. J. Tr.*, April, 1880.) Chian turpentine "has when fresh a distinctive odor, slightly like the pinaceous turpentines, but much more agreeable and aromatic, according to some resembling citron and jasmine: but there is always a background smell like that of mastic, which becomes more developed and distinct with age, when it has lost the more volatile portion, the essential oil. According to Pereira, the turpentine-like odor is combined with the odor of fennel, and Guibourt says, when kept in a covered glass vessel the odor is strong and agreeable, analogous to that of fennel or the resin of elemi. It probably loses this rapidly. A specimen, bearing Guibourt's name, in the Society's Museum, has now no trace of it, but the mastic odor is very persistent. If the fennel odor be very evident in it I should fear the sample was not genuine, as in a statement made in the *Lancet* the writer says what is sold as Chian turpentine 'is either greatly adulterated or a wholly factitious article, manufactured from black resin, Canada balsam, and the essential oils of fennel and juniper.' The taste of genuine Chian turpentine resembles that of mastic; it is agreeable and free from the characteristic bitterness and acridity of the pinaceous turpentines."

† For details as to the varieties of European turpentine and the methods of procuring them, consult *A. J. P.*, 1878, 69, 479; *Proc. A. P. A.*, xxiv. 203; *P. J. Tr.*, viii. 283; x. 447.

take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, called *oil of turpentine*, the composition of which is essentially uniform, it being composed of several terpenes (pinene, dipentene, and sylvestrene) of the formula $C_{10}H_{16}$, the residue consisting exclusively of resin. (See *Oleum Terebinthinæ* and *Resina*.) Both the cones and the leaves of *Abies pectinata* yield oils known respectively as *pine cone oil* and *pine needle oil*. According to *Schimmel & Co.'s Report* for April, 1897, they both contain pinene, limonene, and bornyl acetate. The oil from *Pinus sylvestris*, known as *fir oil*, also contains bornyl acetate to the amount of 12 per cent., according to *Schimmel & Co.'s Report* for October, 1897, 47. On the other hand, the oil from *Larix europæa*, known as *larch needle oil*, contains 8·1 per cent. of bornyl acetate and 6·14 per cent. of free borneol. (*Ibid.*, 61.) H. Schiff affirms that the odor of turpentine is due to the presence of a product of oxidation, probably a camphoric aldehyde, $C_{10}H_{16}O_3$, which, with the odor, may be removed by shaking the turpentine with sodium bisulphite. A non-odorless turpentine may also be obtained by washing with soda solution and distilling in an atmosphere of carbonic anhydride. From the experiments of M. Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Méd.*, 1830, 94.) According to M. Thierry, the same result is obtained by the addition of one part of calcium hydrate to thirty-two parts of common European turpentine. (*Journ. de Pharm.*, 3e sér., i. 315.) Crouzel (*P. J. Tr.*, 1892, 11) found tannin in the bark of *P. maritima*, associated with a peculiar reddish-yellow coloring matter, representing tannin in the process of formation.

Medical Properties and Uses. The effects of the turpentines upon the system are dependent entirely on their volatile oil. They are stimulant, diuretic, anthelmintic, and in large doses laxative. When taken internally or applied to the skin, they communicate a violet odor to the urine, and, if continued for some time, produce an irritation of the mucous membrane of the urinary passages, amounting frequently to strangury. The last effect is less apt to be experienced when they operate upon the bowels. Externally applied they act as rubefacients. Their medical virtues were known to the ancients. At present they are less used than formerly, having been superseded by their volatile oils. They are, however, occasionally prescribed in *leucorrhœa*, *gleet*, and other *chronic diseases of the urinary passages;* in *piles* and *chronic inflammation* or *ulceration of the bowels;* in *chronic catarrhal affections;* and in various forms of *rheumatism*, especially *sciatica* and *lumbago*. The white turpentine is usually employed in this country. It may be given in the shape of pill made with powdered liquorice root; in emulsion with gum arabic or yolk of egg, loaf-sugar, and water; or in electuary formed with sugar or honey. The dose is from twenty grains to a drachm (1·3–3·9 Gm.). In the quantity of half an ounce or an ounce (15·5 or 31·1 Gm.), triturated with the yolk of an egg, and mixed with half a pint of mucilaginous liquid, it forms an excellent injection in cases of ascarides and of constipation with flatulence.

Paracelsus is said to have used *Chian turpentine* in the treatment of *cancer* (Tweedy, *London Lancet*, 1880, i. 582), and Mr. Clay, of London, has also commended it very highly. It should be given in emulsion in doses of five grains, increased as rapidly as the patient will bear it. The pill form is ineligible.* It may also be applied locally.

The vapor of turpentine, employed as a vapor-bath, has been highly recommended in obstinate *chronic rheumatism*. According to M. A. Chevandier, it is borne well for about twenty-five minutes, at a temperature of from 60° to 71·1° C. (140° to 160° F.), producing acceleration of the pulse, and copious sweating, sometimes accompanied with a confluent eruption. (*Arch. Gén.*, 4e sér., xxviii. 80.)

TERPINI HYDRAS. U. S. Terpin Hydrate.

$C_{10}H_{18}(OH)_2 . H_2O$; 189·58. (TĘR-PĪ'NĪ HĪ'DRĂS.)

"The hydrate of the diatomic alcohol Terpin. Terpin hydrate should be kept in well-stoppered bottles." *U. S.*

This new official may be made by the following process. A mixture of four parts of rectified oil of turpentine, three parts of alcohol (sp. gr. 0·863), and one part of nitric acid is put in

* Mr. Clay uses pills containing each 3 grains of Chian turpentine and 2 grains of sulphur, but they are apt to lose their shape. Three grains of Chian turpentine and 1½ grains of light magnesia make a pill which retains its shape tolerably well, but it is perfectly insoluble, losing, according to Martindale, barely one-tenth of its weight in passing through the body. The pill made with lycopodium is also said to be indigestible.

large, shallow porcelain dishes and allowed to stand for three or four days. The crystals which have formed are then collected and allowed to drain thoroughly; they are then pressed between sheets of absorbent paper, and recrystallized in a cold solution of 95 per cent. of alcohol. The product is about 12 per cent of the original turpentine oil. E. T. Hahn proposed the use of methyl alcohol (sp. gr. 0·801) in place of alcohol, in making terpin hydrate. (*A. J. P.*, 1897, 73.) Terpin hydrate is officially described as in "colorless, lustrous, rhombic prisms, nearly odorless, and having a slightly aromatic and somewhat bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in about 250 parts of water, and in 10 parts of alcohol; in 32 parts of boiling water, and in 2 parts of boiling alcohol; also soluble in about 100 parts of ether, 200 parts of chloroform, or 1 part of boiling glacial acetic acid. Terpin Hydrate melts at 116° to 117° C. (240·8° to 242·6° F.), with the loss of water, and, at the temperature of boiling water, sublimes in fine needles. When heated in a flask adapted for distillation, it first loses water. At 258° C. (496·4° F.) anhydrous terpin distils over without decomposition, soon solidifying to a crystalline, hygroscopic mass, which melts at 102° to 105° C. (215·6° to 221° F.). When strongly heated on platinum foil, it burns with a bright, smoky flame, leaving no residue. Terpin Hydrate is dissolved by sulphuric acid with an orange-yellow color. If to its hot, aqueous solution a few drops of sulphuric acid be added, the liquid will become turbid and develop a strongly aromatic odor. Terpin Hydrate should not have the odor of turpentine, and its hot, aqueous solution should not redden blue litmus paper (absence of *adhering acid*)." *U. S.* The anhydrous *terpin* $C_{10}H_{18}(OH)_2$, obtained from it by the loss of water has the characters of a glycol. Dipentene dihydrochloride is its hydrochloric acid ether. By the loss of water the terpin then becomes *terpineol*, $C_{10}H_{17}(OH)$, and finally yields dipentene, terpinene, or terpinolene, according to the conditions of its treatment. Bouchardat and Voiry obtained terpineol in crystals which melt at 35° C. and remain in superfusion for long periods. (*Ann. der Chem.*, 1893, 103.) For Wallach's researches on crystallized terpineol, see *P. J. Tr.*, 1893, 2.

Medical Properties and Uses. Terpin was first physiologically investigated by Lépine, in 1885, who found it to act both upon the mucous membranes and upon the nervous system in a manner similar to the oil of turpentine. It has since been used in *chronic bronchitis* and in the advanced stages of *acute bronchitis*, especially when the secretion is unusually free; also in *chronic cystitis* and *gonorrhœa*. Dose, from two to three grains (0·13–0·2 Gm.), from four to six times a day, in pill or in emulsion.

THYMOL. U. S., Br. Thymol.

$C_{10}H_{14}O$; 149·66. (THĪ'MŎL.) $C_{10}H_{13}OH$; 150.

"A phenol occurring in the volatile oils of Thymus vulgaris, Linné, Monarda punctata, Linné (nat. ord. Labiatæ), and Carum Ajowan (Roxburgh), Bentham et Hooker (nat. ord. Umbelliferæ). It should be kept in well-stoppered bottles." *U. S.* "A crystalline substance, $C_6H_3.OH.CH_3.C_3H_7$, obtained from the volatile oils of Thymus vulgaris, Linn., Monarda punctata, Linn., and Carum copticum, Benth. and Hook. f., purified by recrystallization from alcohol." *Br.*

This substance has attracted considerable attention from its possession of antiseptic properties analogous to those of carbolic and salicylic acids and creosote, with which it is also analogous in composition. It may be obtained by submitting the volatile oils of several plants to a prolonged refrigeration, under the influence of which it crystallizes. Thus, it has been obtained from *Monarda didyma*, Linn., *M. punctata*, *Ammi copticum*, and *Ptychotis ajowan*. *Ocymum viride*, Willd., a plant used in Liberia as an antiperiodic, so closely resembles thyme in its odor that it has been thought to contain thymol. (*Proc. A. P. A.*, xxvi. 168.) Thymol is obtained from the oils of thyme by distilling off from these the larger part of the hydrocarbons and adding warm caustic soda solution to the residue, which combines with the thymol. The mixture is diluted after a time with hot water, which causes the unattacked oil to rise to the top. From the soda solution hydrochloric acid sets the thymol free. This collects as an oily layer, which on cooling will crystallize if a crystal of thymol be added.

Properties. Thymol melts at 44° C. (111·2° F.), but does not readily resolidify unless touched by a solid body or by a crystal of thymol. It boils at 220° to 230° C. (428° to 446° F.). It is very slightly soluble in water, but is very soluble in alcohol, and more freely in proportion to the concentration of the menstruum. It is dissolved by ether and the fixed

oils, and has no rotatory power as regards polarized light. The alkalies unite with it to form soluble salts. Like creosote, it has the property of combining with animal tissues and thus protecting them against putrefaction. Its formula is $C_{10}H_{14}O$, or $C_6H_3\begin{cases}OH\\CH_3\\C_3H_7\end{cases}$; while *thymene*, with which it is associated in the oil, is a hydrocarbon, isomeric with the oil of turpentine, and having the composition $C_{10}H_{16}$. As its formula indicates, it is a *propyl-cresol;* and it has been made synthetically by Widmann from cuminol (isopropyl benzaldehyde). This is first nitrated, then by means of phosphorus pentachloride the oxygen of the aldehyde group replaced by chlorine, the nitro group reduced, the chlorine replaced by hydrogen, and the amide group replaced by hydroxyl. The successive changes are thus indicated: $C_6H_4\begin{cases}C_3H_7\\COH\end{cases}$; $C_6H_3\begin{cases}NO_2\\C_3H_7\\COH\end{cases}$; $C_6H_3\begin{cases}NO_2\\C_3H_7\\CHCl_2\end{cases}$; $C_6H_3\begin{cases}NH_2\\C_3H_7\\CHCl_2\end{cases}$; $C_6H_3\begin{cases}NH_2\\C_3H_7\\CH_3\end{cases}$; $C_6H_3\begin{cases}OH\\C_3H_7\\CH_3\end{cases}$. Thymol is officially described as in "large, colorless, translucent crystals of the hexagonal system, having an aromatic thyme-like odor, and a pungent, aromatic taste, with a very slight caustic effect upon the lips. Its specific gravity as a solid is 1·069 at 15° C. (59° F.), but when liquefied by fusion it is lighter than water. It melts at 50° to 51° C. (122° to 123·8° F.), remaining liquid at considerably lower temperatures. When triturated with about equal quantities of camphor, menthol, or chloral, it liquefies. Soluble in about 1200 parts of water at 15° C. (59° F.), and in less than its own weight of alcohol, ether, or chloroform; also readily soluble in carbon disulphide, glacial acetic acid, and in fixed or volatile oils. Its alcoholic solution is optically inactive. If a very small crystal of Thymol be dissolved in 1 C.c. of glacial acetic acid, and then 6 drops of sulphuric acid and 1 drop of nitric acid be added, the liquid will assume a deep bluish-green color. If 1 Gm. of Thymol be heated in a test-tube, in a water-bath, with 5 C.c. of a 10-per-cent. solution of sodium hydrate, a clear, colorless, or very slightly reddish solution should be formed, which becomes darker on standing, but without the separation of oily drops (absence of *thymene* or lævogyrate *pinene*, $C_{10}H_{16}$). If to this solution a few drops of chloroform be added, and the mixture agitated, a violet color will be produced. When a crystal of Thymol is heated in an open capsule, or in a watch-glass, on a water-bath, it should gradually volatilize, leaving no residue (absence of *paraffin*, *spermaceti*, etc.)." *U. S.* "The crystals sink in cold water, but on heating the mixture to a temperature of 110° to 125° F. (43·3° to 51·7° C.) they melt and rise to the surface. Almost insoluble in cold *water*, freely soluble in *alcohol* (90 per cent.), *ether*, and solutions of alkalies. The crystals volatilize completely at the temperature of a water-bath. A solution of Thymol in half its bulk of *glacial acetic acid*, warmed with an equal volume of *sulphuric acid*, assumes a reddish-violet color." *Br.*

Medical Properties. The disagreeable odor of carbolic acid induced M. Bouillon, a French pharmaceutist, to search for a substance with the important practical properties of carbolic acid without disagreeable smell. Such a substance he found in thymol. In a concentrated state it has caustic properties, which render it very useful for the cauterization of the dental nerves. Dissolved in water in the proportion of 1 to 1000, with the addition of a little alcohol, it is useful in the dressing of *unhealthy wounds.* Combined in the proportion of 4 parts of the acid with 4 of tannin, 2 of aniline, and 100 of glycerin, it has been used with great success by Dr. Paquet for the preservation of anatomical specimens. For the dressing of wounds, it may be used in the form of a lotion composed of 1 part of the acid, 4 parts of alcohol of 85°, and 995 parts of distilled water. In the form of ointment, it may be employed incorporated with lard in the proportion of from two to twenty grains to an ounce. It has been used by surgeons, but has been found less advantageous than salicylic acid. Its fragrant odor, whilst fitting it for use about the mouth, is often a great nuisance in the hospital ward, on account of attracting flies. It has been exhibited internally as antipyretic by Balz in the amount of thirty grains (1·95 Gm.) a day, causing ringing in the ears, deafness, sweating, and in some cases alarming collapse. Dr. F. P. Henry has found it a useful intestinal antiseptic, especially valuable in catarrh of the intestines, given in doses of two and a half grains (0·162 Gm.) every six hours, in pill or capsule. Injected into the veins of dogs, it produces death by failure of respiration, and its general physiological action is probably very similar to that of carbolic acid.

THYROIDEUM SICCUM. Br. Dry Thyroid.

(THĪ-RŌĬ'DḘ-ŬM SĬC'CṶM.)

"A powder prepared from the fresh and healthy thyroid gland of the sheep. Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after killing. Cut the glands across, and reject any which contain cysts, are hypertrophied, or otherwise abnormal. Mince finely the healthy glands, and dry at a temperature of 90° to 100° F. (32·2° to 37·8° C.); powder the dried product; remove all fat from it by treatment with *petroleum spirit;* and again dry the residue." *Br.*

The British Pharmacopœia introduced this preparation in the 1898 edition (see also *Liquor Thyroidei*, p. 826). The process for dry thyroid is given above; the objection to its use is that the powder may contain bacteria, or even ptomaines, if great care is not used in its preparation; it is also stated that glycerin does not dissolve all of the thyroiodin which is the principal active constituent, and "Thyroid Solution" cannot be thoroughly representative.

Properties. Dry thyroid is officially described as "A light dull-brown powder, with a very faint meat-like odor and taste, and free from any flavor of putrescence. It is liable to become damp on exposure to the air, and then deteriorates." *Br.*

In 1895 Baumann (*Zeits. f. Phys. Chemie*, Bd. xxi.) announced the discovery in the thyroid body of *thyroiodin*, and his allegation that it is the active principle of the thyroid gland has been confirmed by E. Roos, Arthur Hennig, Treubel, Ewall, E. Levy, and others; so that its remedial activity seems to be established, although it is probable that there is a second active substance in the gland. *Thyreoantitoxin* of Fränkel (*Aerztl. Central Anzeiger*, 1895) contains no iodine and appears not to be active. *Iodo-globulin*, which is believed to be active, is destroyed by boiling in acid or alkaline solutions, but may be extracted by macerating the glands in cold water and evaporating the solution at 100° C. (212° F.). Thyroiodin exists in small proportion (1 in 333). E. C. C. Stanford has furnished the following process for the mixed powder termed *thyroglandin*. "The thyroid glands, freed from fat and minced, are first macerated in four to five times their weight of cold water, using ice if necessary in summer to keep down the temperature to 50° F., for twenty-four hours, and this maceration is repeated. The solutions are filtered off and evaporated to dryness at a temperature not exceeding 212° F. The extract is powdered, and represents the iodo-globulin and a small proportion of saline matter. The residue from the cold water maceration is boiled for one hour with a 1 per cent. solution of caustic soda (in the proportion of 1 per cent. of caustic soda to the original weight of the glands). The solution is allowed to cool to deposit the fat, and filtered off. This solution is then carefully neutralized with hydrochloric acid and evaporated to dryness at 212° F.; the residue, which contains all the thyroiodin, is then powdered and mixed with the iodo-globulin obtained in the first process. The resulting powder is thyroglandin." (*Year-Book of Pharmacy*, 1898, 354.)

Medical Properties. It has been proved upon the human being by Kocher, of Berne, and upon monkeys by Horsley, of London, that the removal of the thyroid body is followed by the production of increasing weakness, associated with swelling of the body, enlargement and thickening of the skin, mucoid exudation into the subcellular tissue, and a very extraordinary slowing of all functions,—a condition which progresses until the subject sinks into a state of complete apathy, with subnormal temperature and failure of all vital functions. This congeries of symptoms is the same as that previously described under the name of *myxœdema* by Ord. Both surgical and idiopathic myxœdema have in a large number of cases been treated by the use of the thyroid extract, with such extraordinary results as to leave no doubt but that this extract is a specific in myxœdematous diseases, and is also an extremely valuable remedy in *cretinism*, a condition very closely allied to myxœdema.

In a number of cases the free continuous exhibition of the thyroid gland has been followed by progressive loss of weight, shortness of breath, weak and rapid pulse, and great nervousness, constituting the condition known as *thyroidism*. The loss of weight, which is very marked, appears to be in part accounted for by an increased destruction of the nitrogenous substances of the body, with a corresponding increase in the output of urea, but in chief part to the result of the destruction of fat and other carbohydrates. From studies on the lower animals and upon man it is plain that the thyroid gland contains in it some substance which pronouncedly affects nutrition; a fact the recognition of which by the profession has led to the experimental use of the thyroid body in a very large number of cases connected with disturbed nutrition. It seems well established that the drug is valuable in that form of *goitre*

which is indigenous to Switzerland, but is much more apt to do harm than good in *exophthalmic goitre* or *Basedow's disease*. Also, that it is often of great service in the treatment of *obesity*. It has been widely used in various forms of *insanity* and in various diseases of the skin, with, on the whole, not satisfactory results; so that its employment in these affections may be said to be already passing out of vogue. Great advantage, however, is asserted to have followed its use in cases of *keloidal scars* where there has been excessive formation of fibrous tissues.

In all these cases the thyroid preparation acts simply by supplying to the system an organic principle which the thyroid body in the patient has failed to produce in sufficient quantity. The thyroid body is, therefore, in most cases a palliative, so that its continuous administration is necessary, large doses being first given until the evils wrought by the absence of the thyroid gland have been overcome, and smaller doses being afterwards exhibited to maintain the bodily health which has been restored by the larger doses. The raw or slightly boiled thyroid gland may be used to the amount of from a quarter to half of the gland of the sheep daily, but the preparations are perhaps equally efficacious and certainly much better taken by patients. Of the dried extract the dose is from three to five grains, three times a day, in capsule. Under the name of *iodothyrin* there is sold commercially a substance claiming to be thyroiodin with sugar; it is said to be of such strength that one gramme of it contains 0·3 milligramme of iodine and is equivalent to one gramme of the fresh gland. A dose of from one to two grammes a day may be given to an adult. The rule is, in all cases in which the thyroid body is used, to increase the dose until a satisfactory result is obtained or slight evidences of thyroidism appear.*

TINCTURÆ. U. S. Tinctures.

(TĬNC-TŪ'RÆ.)

Teintures, *Fr.*; Tinkturen, *G.*

Tinctures, in the pharmaceutical sense of the term, are alcoholic solutions of medicinal substances, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures*. The advantages of alcohol as a menstruum are that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved, while it leaves behind some inert substances which are dissolved by water. In no instance, however, is absolute alcohol employed. The U. S. Pharmacopœia directs it of the sp. gr. 0·820, the British, 0·834. When of these densities it contains water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol, while its solvent power in relation to bodies soluble in that fluid is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to official alcohol, as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, whilst at the same time it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating, although a few tinctures when prepared with proof spirit or diluted alcohol undergo some deterioration in time, in consequence of acetous fermentation taking place in the alcoholic fluid. The best preventive is to keep them in full and well-closed bottles, at a low temperature. The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consists of equal volumes of official alcohol and water, and has the sp. gr. 0·938, while the British has four official diluted alcohols,—70, 60, 45, and 20 per cent. Alcohol or rectified spirit is preferred as a solvent when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but also by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water added to an alcoholic solution of one of these bodies produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed when the substance is soluble both in alcohol and in water; or when one or more of the ingredients are soluble in the one fluid and one or more in the other, as in the case of vegetable bodies which contain extractive or tannin, or the natural salts of the alkaloids, or gum united with resin or

* In a very elaborate series of experiments, R. H. Cunningham believes that he has proved that the symptoms of thyroidism are simply produced by secondary products of decomposition in the thyroid body during the making of these preparations, and may be caused by extracts from almost any kind of animal tissues; and has reached other conclusions gainsaying the value of the thyroid body as a therapeutic agent. A discussion of this matter would require too much space to be entered into here. Suffice it at present to state that the clinical and experimental evidences of the value of the thyroid gland in the conditions spoken of seem to us unimpugnable.

essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used. In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a moderately fine than of a very fine powder: the proper degree of fineness depends, however, upon the ease with which the menstruum extracts the soluble principles.

Tinctures were at one time universally prepared by maceration or digestion. Our own Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. The latter plan was preferable, as it was more convenient and equally effectual, the lower temperature being compensated by the longer maceration. In several instances in which maceration is ordered in the Pharmacopœia, it is still continued for seven days; but the period is very properly altered to suit the character of the substance acted on, and sometimes continued no longer than is necessary for its solution, when it is wholly soluble, as in the tinctures of iodine and tolu. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed; when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering.

The plan of preparing tinctures by percolation has been extensively adopted, and has been found to answer well when skilfully executed. In the present edition of our Pharmacopœia, percolation has been adopted as the rule, maceration being directed in a few instances in which it was deemed preferable. The British Pharmacopœia, preferring maceration or digestion in several instances, has adopted percolation as a rule, but, as if unprepared to trust this process alone, has combined with it a preliminary maceration of forty-eight hours, and a final expression, so as to separate the last remains of the tincture from the dregs. Perhaps these modifications may be desirable in instances where the operator is not sufficiently skilful; but percolation, properly managed, is of itself adequate to all the desired purposes, even to the removal of almost the last drop of impregnated menstruum from the dregs; and in our Pharmacopœia it is taken for granted that the apothecary has acquired the requisite skill. Where the operator cannot trust himself in this respect, it would be better to recur to the old method of maceration for two weeks. The reader will find rules for the proper management of the process of percolation at page 529. It has been objected to this process that it yields tinctures of variable strength, according to the skill with which it is conducted; but, from numerous experiments performed, in reference to this point, by M. H. Buignet, of Paris, it appears that the tinctures made by percolation are quite as equable in strength as those prepared by maceration, while they uniformly contain more of the soluble matter of the drug in proportion to the quantity of menstruum. The same writer states that he has constantly found three parts of alcohol, used in this method, to one of the material acted on, sufficient to exhaust drugs almost wholly of their soluble matter. He has derived no advantage from the preliminary maceration usually practised. M. Personne, however, has inferred, from his own observation, that five parts of alcohol are required by most substances. Our own Pharmacopœia generally adopts this. Mr. R. F. Fairthorne (*A. J. P.*, 1881, p. 308), in the preparation of hydro-alcoholic tinctures, prefers to macerate the ingredients for twenty-four hours alone in the alcohol, then filter, and mix the filtrate with the required quantity of water and percolate the dregs with the mixture. This plan might be of service in the case of a few drugs which are difficult to exhaust of their activity, but it would involve a useless expenditure of labor and time if used in the majority of official tinctures, and precipitation would be more common. It has been contended in opposition to percolation, applied to the preparation of tinctures, that the menstruum is apt to load itself with substances which, after the preparation of the tincture, are deposited, carrying down with them more or less of the active matter; but M. Vauflart asserts that more than twenty years of observation has demonstrated to him that tinctures by displacement, properly filtered, deposit no more at the end of a certain period than do those prepared by maceration. Besides, upon the same authority, this tendency to deposition may be easily obviated by mixing all the liquids proceeding from the percolation, and allowing the mixture to stand for a day before filtering. The tinctures thus obtained are, he states, richer than those furnished by ordinary maceration, and time produces in them only insignificant

changes. (*Journ. de Pharm.*, 4e sér., iv. 411, 1866.) Finally, all agree that the percolated tinctures are apt to contain more of the soluble matter of the drug; and the objections resolve themselves altogether into a question of skill on the part of the operator.

The method of making tinctures by diluting fluid extracts, except in a few special cases, is not to be recommended. The menstruum directed for the fluid extract is intentionally not identical with that used for the tincture, and precipitation of active constituents often ensues when this easy method is employed. Owing to the larger dose of the tinctures, and consequently less degree of concentration, a larger proportion of water can be used in their menstrua than in fluid extracts, and this is a distinct advantage, as tinctures are frequently ordered in prescriptions in combination with aqueous solutions.

Another mode of exhausting medicines by spirit has been proposed by Dr. H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks; and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. For this mode of preparing tinctures Mr. Samuel Gale has proposed the use of a cylindrical stone-ware vessel with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum. (*A. J. P.*, xxii. 381.) The infusion jars described and figured on page 729 may be used also for preparing tinctures by maceration.

Tinctures prepared by adding alcohol to the expressed juices of plants have been long in use on the continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices.* The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. Mr. Squire and Mr. Bentley have paid particular attention to these preparations. According to Mr. Squire, the leaves only of the plants should be used, and, in the case of biennial plants, those exclusively of the second year; and they should be preferably collected when the plant is in full flower. Mr. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for 24 hours and deposited its feculent matter, alcohol of 0·838 is to be added in the proportion of one part by measure to four parts of the juice; and after another period of 24 hours the liquor is to be filtered. This proportion of alcohol has been found sufficient for the preservation of the juice, while it causes the precipitation of the suspended mucilaginous matter. But, though these preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so, as they contain necessarily not only the soluble active matter of the juice, but also that which, when the juice is expressed, is left in the solid residue of the plant.

Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might in some instances be attended with serious inconvenience, by increasing their strength beyond the official standard.

Medicines which act in small doses are most conveniently administered in tinctures, as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

In the revision of the Pharmacopœia of 1890, wherever practicable, the proportion of drug to finished tincture has been made either 20, 15, 10, or 5 per cent. by volume. In the case of very strong or poisonous tinctures it was not deemed advisable to make too great a change in strength, for fear of dangerous results; indeed, it may be questioned by many whether too much change has not been made in the tinctures which do not belong to the dangerous class. Yet progressive pharmacy demands greater uniformity and simplicity in the processes, and it is believed that eventually all the tinctures can be brought into two classes, 20 and 10 per cent.

TINCTURA ACONITI. U. S., Br. Tincture of Aconite.

(TĬNC-TŪ'RĄ ĂC-Q-NĪ'TĪ.)

Tinctura Aconiti Radicis, *U. S.* 1870; Tincture of Aconite Root; Tinctura Aconiti, *P. G.;* Teinture de Racine d'Aconit, *Fr.;* Eisenhuttinktur, *G.*

"Aconite, in No. 60 powder, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Alcohol to *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water. Having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of menstruum, macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Aconite Root, in No. 40 powder, 1 *ounce* (Imperial) or 50 grammes; Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with *four fluid drachms* (Imp. meas.) or twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with two-fifths the proportion of Aconite Root ordered for the Tincture of Aconite of the British Pharmacopœia of 1885." *Br.*

The tincture of the U. S. Pharmacopœia has seven times the strength of the British, and the title was changed from *Tinctura Aconiti Radicis* to *Tinctura Aconiti* in the U. S. 1880 revision. It is much stronger than the Tincture of Aconite Leaves, which is still used occasionally, and made of the strength of two troyounces of powdered aconite leaves in a pint of diluted alcohol; and too much caution cannot be observed to avoid mistaking one tincture for the other. In preparing it, each step of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. As annoyance is often occasioned in powdering aconite by the irritating dust which is apt to rise, it is best prepared by grinding in a mill; and if powdered in a mortar, sufficient alcohol should be added to the root to prevent the rising of the dust. Tartaric acid used in accordance with the researches of Duquesnel in the U. S. 1880 tincture has been abandoned, as it was found to be unnecessary. The dose to begin with is from one to three drops (0·06–0·18 C.c.), repeated, and gradually increased, if necessary, until its peculiar effects are experienced. That of the British tincture is from five to fifteen minims (0·3–0·9 C.c.). The external use of the tincture requires care, as serious symptoms have followed its too free employment. (Case, *Bost. Med. and Surg. Journ.*, Feb. 1872, 74.)*

TINCTURA ALOES. U. S., Br. Tincture of Aloes.

(TĬNC-TŪ'RĄ ĂL'Q-ĒS.)

Teinture d'Aloès, *Fr.;* Aloetinktur, *G.*

"Purified Aloes, in moderately fine powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Liquorice Root, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powders, and, having moistened the mixture with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of Diluted Alcohol, macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Extract of Barbados Aloes, ½ *ounce* (Imperial) or 25 grammes; Liquid Extract of Liquorice, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Alcohol (45 per cent.), *a sufficient quantity.* Place the Extract of Barbados Aloes in a closed vessel with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; set aside for forty-eight hours, occasionally shaking until dissolved; add the Liquid Extract of Liquorice; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

* *Fleming's Tincture of Aconite.* This should always be expressly designated when prescribed. It is considerably stronger than the official; and several deaths have occurred from the use of it. The following is Fleming's formula. Take of the root, carefully dried and finely powdered, *sixteen (troy)ounces:* Alcohol, *sixteen fluidounces.* Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than two drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

The original tincture of aloes of the U. S. Pharmacopœia was prepared with the official diluted alcohol, without the addition of water. The preparation of the U. S. P. 1870 was little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. The process of the Br. Pharm. 1898 shows a marked improvement on the former British tincture. Barbados aloes replaces Socotrine, liquid extract of liquorice is used instead of the solid extract, and the time for making the tincture is reduced from a week to two days. The strength of the British tincture is only one-fourth that of the U. S. tincture. The formula of the U. S. 1890 Pharmacopœia directs liquorice root instead of extract of liquorice, and this permits the use of percolation, which is far preferable to maceration. M. Ménière says of the tincture of aloes that it deposits crystals of aloin, which adhere to the sides of the bottle, and in the upper part of it a yellow resinous matter is seen. (*Journ de Pharm.*, 1861, 289.) The dose as a purgative is from two to four fluidrachms (7·5–15 C.c.), as a laxative from one-half to one fluidrachm (1·9–3·7 C.c.).

TINCTURA ALOES ET MYRRHÆ. U. S. Tincture of Aloes and Myrrh.

(TĬNC-TŪ'RĄ ĂL'Ō-ĒŞ ĔT MĬR'RHÆ.)

Tinctura Aloes Composita, *Lond.;* Elixir Proprietatis Paracelsi, *P. G.;* Elixir de Propriété, *Fr.;* Aloëelixir, *G.*

"Purified Aloes *one hundred grammes* [or 3 ounces av., 231 grains]; Myrrh, *one hundred grammes* [or 3 ounces av., 231 grains]; Liquorice Root, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Having mixed the Aloes, Myrrh, and Liquorice Root, reduce them to a moderately coarse (No. 40) powder. Moisten the powder with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of the menstruum, and macerate for twenty-four hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture has been improved by the addition of liquorice root, which not only communicates an agreeable taste and obtunds the bitterness of the aloes, but also permits the use of percolation. The tincture is a modification of the *elixir proprietatis* of Paracelsus. It is practically identical with the tincture official in 1870. Saffron, which had long been retained in compliance with old-time prejudices, can add little to the efficacy of a preparation, and, being very expensive, was with great propriety omitted in the 1870 revision. It served, however, to impart a rich color to the tincture, the want of which some may consider a defect. The tincture is purgative, tonic, and emmenagogue, and is considerably employed in *chlorosis* and *amenorrhœa* when there is constipation. Dose, from one to two fluidrachms (3·7–7·5 C.c.).

TINCTURA ARNICÆ FLORUM. U. S. Tincture of Arnica Flowers.

(TĬNC-TŪ'RĄ ĂR'NĮ-ÇÆ FLŌ'RŬM.)

Tinctura Arnicæ, *Pharm.* 1870; Teinture d'Arnica, *Fr.;* Arnikatinktur, *G.*

"Arnica Flowers, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Pack the powder firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

There are two tinctures of arnica now official, and it is necessary to add to the title either "Florum" or "Radicis," to distinguish them. The tincture of arnica flowers differs from that official in 1870 in the menstruum selected, which is now diluted alcohol in place of alcohol. The change was advocated by numerous pharmaceutical writers, and there is no question of the ability of the menstruum to exhaust the arnica flowers, if they are tightly packed in the percolator. The principal objection to the change is the greater difficulty that will be experienced in mixing the tincture with liniments containing oily and alcoholic liquids.

In the article upon Arnica, it is stated that arnica is poisonous in overdoses. In the *Lancet* for Nov. 19, 1864 (page 570), Mr. H. Bertin details a case in which a middle-aged man, ten hours after having taken by mistake an ounce of tincture of arnica, was in a state approaching collapse, with sunken and glassy eyes, dilated and insensible pupils, pulse fluttering and over one hundred, skin cold but dry, low and wiry voice, and severe pain in the epigastrium, which

was the first striking symptom that he had experienced, and had come on upon awaking from sleep, about eight hours after he swallowed the poison. The mind was apparently clear. Though in great danger, he recovered, under the use of opium and brandy with external heat.

Either alone, or diluted with water, soap liniment, etc., tincture of arnica is often applied popularly to *bruises*, *sprains*, *tumors*, and local *rheumatic pains*, under the impression that it has extraordinary healing powers. It probably acts favorably in some instances as a general irritant. In some skins it produces a violent eczematous inflammation. If given internally, the dose would be from ten to thirty minims (0·6–1·9 C.c.), increased until some effect was produced.

TINCTURA ARNICÆ RADICIS. U. S. (Br.) Tincture of Arnica Root.

(TĬNC-TŪ′RĄ ĂR′NĮ-ÇÆ RĄ-DĪ′CĮS.)

Tinctura Arnicæ, *Br.*

"Arnica Root, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of the menstruum, and macerate for twenty-four hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Arnica Rhizome, in No. 40 powder, 1 *ounce* (Imperial) or 50 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The British tincture has about one-half the strength of the U. S. preparation. Dose, from twenty minims to half a fluidrachm (1·25–1·9 C.c.).

TINCTURA ASAFŒTIDÆ. U. S., Br. Tincture of Asafetida.

(TĬNC-TŪ′RĄ ĂS-Ą-FŒT′Į-DÆ.)

Teinture d'Asefétide, *Fr.;* **Stinkasanttinktur**, *G.*

"Asafetida, bruised, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Asafetida with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and macerate for seven days, in a closed vessel; then filter through paper, adding, through the filter, enough Alcohol to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Asafetida, bruised, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Place the Asafetida in a closed vessel with *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the Alcohol; set aside for seven days, with occasional agitation; filter; pass sufficient of the alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The British tincture (1898) was increased in strength 60 per cent., and it is now identical with the U. S. P. preparation. This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It is somewhat stronger than the tincture official in 1870, which is an improvement, particularly in view of the gradual decline in the quality of the drug. The dose is from thirty minims to a fluidrachm (1·9–3·7 C.c.).

TINCTURA AURANTII AMARI. U. S. (Br.) Tincture of Bitter Orange Peel.

(TĬNC-TŪ′RĄ ÂU-RĂN′TĮ-Ī Ą-MĀ′RĪ—âw-răn′shę-ī.)

Tinctura Aurantii, *Br.;* **Teinture d'Ecorce d'Oranges amères**, *Fr.;* **Pomeranzenschalentinktur**, *G.*

"Bitter Orange Peel, in No. 30 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 266 minims] of the menstruum, and macerate for twenty-four hours; then pack

it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Fresh Bitter Orange Peel, cut small, 5 *ounces* (Imperial) or 250 grammes; Alcohol (90 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

It is the peel of the Seville orange that is directed in this process; and the outer part only is active. The substitution of fresh for dried orange peel has been proposed in England, and its propriety considerably discussed. (See *P. J. Tr.*, Nov. 9, 1872, also April 4, 1874.) Indeed, it met with so much favor as to be introduced in the 1885 revision of the British Pharmacopœia, and was used in the *Tinctura Aurantii Recentis, Br.;* but in the Br. Pharm. 1898 the name was changed to *Tinctura Aurantii.* It will be seen that the U. S. and British tinctures are not identical, the former having a greenish-brown color and containing some hesperidin or bitter principle. The U. S. Tincture of Sweet Orange Peel (see next article) closely resembles the British Tincture of Orange. The tincture from the fresh peel is less powerful as a bitter than this preparation, but is much superior in aroma and flavor. (See *Tinctura Aurantii Dulcis.*) The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures. The dose is from one to two fluidrachms (3·7–7·5 C.c.).

TINCTURA AURANTII DULCIS. U. S. Tincture of Sweet Orange Peel.

(TĬNC-TŪ'RĄ ÂU-RĂN'TĮ-Ī DŬL'CĮS.)

"Sweet Orange Peel, taken from the fresh fruit, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Orange Peel (which should be as free as possible from the inner, white layer), previously cut into small pieces, with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and macerate for twenty-four hours; then pack it moderately in a conical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture was introduced for the first time in the U. S. P. 1880, and was designed to furnish a highly flavored alcoholic preparation of orange. The peel should be *grated:* the official direction to *cut it into small pieces* is not definite enough if a successful percolation is desired. This tincture has no peculiar medicinal properties, but is used as a pleasant adjuvant.

TINCTURA BELLADONNÆ FOLIORUM. U. S. (Br.) Tincture of Belladonna Leaves.

(TĬNC-TŪ'RĄ BĔL'LĄ-DŎN'NÆ FŌ-LĮ-Ō'RŬM.)

Tinctura Belladonnæ, *Br., U. S. P.* 1880; Teinture de Belladone, *Fr.;* Belladonnatinktur, *G.*

"Belladonna Leaves, in No. 60 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Liquid Extract of Belladonna, 2 *fl. ounces* (Imperial measure) or 60 cubic centimetres; Alcohol (60 per cent.), *a sufficient quantity.* To the Liquid Extract of Belladonna add enough of the Alcohol to form *thirty fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of the Tincture; set aside for twenty-four hours; filter. On evaporation to a low bulk, and subsequent treatment by the analytical process employed for 'Extractum Belladonnæ Liquidum,' 100 cubic centimetres of the Tincture should yield not less than 0·048 nor more than 0·052 gramme of alkaloid." *Br.*

In the U. S. P. 1890 the name of this tincture has been changed to *Tinctura Belladonnæ Foliorum*, for the sake of greater precision. The British tincture (1898) is made by diluting the assayed fluid extract of belladonna root, and is undoubtedly more uniform in composition than would be the unassayed tincture made from the leaves. It is probably three times the strength of the former British tincture.

The U. S. tincture is an efficient preparation when made from the recently dried leaves; but the imported leaves are of very uncertain strength, and a tincture prepared from them is to be less relied upon than the extract. The dose is from fifteen to thirty drops (0·9–1·9 C.c.). That of the British tincture is from five to fifteen minims (0·3–0·9 C.c.).

TINCTURA BENZOINI. U. S. Tincture of Benzoin.

(TĬNC-TŪ'RĄ BĔN-ZŌ-Ī'NĪ.)

Tinctura Benzoës, *P. G.;* Teinture de Benjoin, *Fr.;* Benzoëtinktur, *G.*

"Benzoin, in moderately coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powder with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and macerate for seven days, in a closed vessel; then filter through paper, adding, through the filter, enough Alcohol to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This tincture may be exhibited in doses of from twenty minims to half a fluidrachm (1·25–1·9 C.c.), but was, no doubt, introduced into the Pharmacopœia chiefly or solely for the purpose of adding to ointments to prevent rancidity.

TINCTURA BENZOINI COMPOSITA. U. S., Br. Compound Tincture of Benzoin.

(TĬNC-TŪ'RĄ BĔN-ZŌ-Ī'NĪ CŌM-PŎS'Ĭ-TĄ.)

Tinctura Balsamica, Balsamum Commendatoris, Elixir Traumaticum; Teinture balsamique, Baume du Commandeur de Permes, *Fr.;* Persischer Wundbalsam, *G.*

"Benzoin, in coarse powder, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Purified Aloes, in coarse powder, *twenty grammes* [or 309 grains]; Storax, *eighty grammes* [or 2 ounces av., 360 grains]; Balsam of Tolu, *forty grammes* [or 1 ounce av., 180 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Benzoin, Aloes, Storax, and Balsam of Tolu with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and digest the mixture, at a temperature not exceeding 65° C. (149° F.), for two hours in a closed vessel; then filter through paper, adding, through the filter, enough Alcohol to make the Tincture, when cold, measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Benzoin, in coarse powder, 2 *ounces* (Imperial) or 100 grammes; Prepared Storax, 1½ *ounces* (Imp.) or 75 grammes; Balsam of Tolu, ½ *ounce* (Imp.) or 25 grammes; Socotrine Aloes, 160 *grains* or 18·3 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Place the Benzoin, Storax, Balsam of Tolu, and Aloes with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol in a closed vessel, set aside for two days, frequently agitating; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

This tincture is a stimulating expectorant, occasionally used in *chronic catarrhal affections*. It has been recommended also in *chronic dysentery*, with a view to its alterative action on the ulcerated surface of the colon; but it is principally employed as a local application to *indolent ulcers*, *chapped nipples*, etc. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur*, *Wade's balsam*, *Friar's balsam*, *Jesuits' drops*, *Turlington's balsam*,* etc., which were formerly in repute, and are still esteemed among the vulgar, as pectorals and vulneraries. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms (1·9–7·5 C.c.). A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.

TINCTURA BRYONIÆ. U. S. Tincture of Bryonia.

(TĬNC-TŪ'RĄ BRĪ-Ō'NĮ-Æ.)

Teinture de Bryone, *Fr.;* Zaunrübetinktur, *G.*

"Bryonia, recently dried, and in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture is used as a cathartic in doses of from one to two fluidrachms (3·7–7·5 C.c.).

* The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij, Benzoin ℥xij, Liquid Storax ℥iv, Socotrine Aloes ℥j, Peruvian Balsam ℥ij, Myrrh ℥j, Angelica Root ℥ss, Balsam of Tolu ℥iv, Extract of Liquorice Root ℥iv. Digest for ten days, and strain. (*Journ. of the Phila. Coll. of Pharm.*, v. 28.)

TINCTURA BUCHU. Br. Tincture of Buchu.

(TĬNC-TŪ'RĄ BŪ'ÇHŪ.)

Teinture de Bucco, *Fr.;* Buchutinktur, *G.*

"Buchu Leaves, in No. 20 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was increased 60 per cent. in the last revision of the Br. Pharm. It has the virtues of buchu leaves, and may be given in the dose of from one to two fluidrachms (3·7–7·5 C.c.), either simply diluted with water or as an addition to the infusion of the leaves.

TINCTURA CALENDULÆ. U. S. Tincture of Calendula.

(TĬNC-TŪ'RĄ CĄ-LĔN'DŬ-LÆ.)

Teinture de Fleurs de Tous-les-Mois, *Fr.;* Ringelblumetinktur, *G.*

"Calendula, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture has been improved in the 1890 revision by substituting alcohol as a menstruum for the diluted alcohol used in the 1880 process. It is employed externally for the same purposes as tincture of arnica flowers. When made with diluted alcohol, some precipitation takes place; alcohol is therefore preferable as a menstruum, and on account of the tincture being used externally makes it more efficient therapeutically.

TINCTURA CALUMBÆ. U. S., Br. Tincture of Calumba.

(TĬNC-TŪ'RĄ CĄ-LŬM'BÆ.)

Tinctura Colombo; Teinture de Colombo, *Fr.;* Kolombotinktur, *G.*

"Calumba, in No. 20 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, macerate for twenty-four hours; then pack it in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Calumba Root, in No. 20 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

Mr. Joseph Ince recommends that the tincture be prepared from the root as found in commerce, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*P. J. Tr.*, xiv. 491.) No. 20 powder is now directed instead of the No. 50 powder used in the U. S. P. 1870.* Tincture of calumba may be added to tonic infusions or decoctions, to increase their stimulant power, but, like all the other bitter tinctures, should be used with caution. The dose is from one to two fluidrachms (3·7–7·5 C.c.).

TINCTURA CANNABIS INDICÆ. U. S., Br. Tincture of Indian Cannabis.

(TĬNC-TŪ'RĄ CĂN'NĄ-BĬS ĬN'DĮ-ÇÆ.)

Tinctura Cannabis, *Pharm.* 1870; Tincture of Hemp; Tincture of Indian Hemp; Tinctura Cannabis Indicæ, *P. G.;* Teinture de Chanvre Indien, *Fr.;* Indischhanftinktur, *G.*

"Indian Cannabis, in No. 40 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces,

* *Tincture of Calumba.* J. B. Moore recommends the following process. Calumba, in powder No. 20, 4 troy oz.; alcohol, 22 fl.oz.; glycerin and water, each 5½ fl.oz.; dilute alcohol, q. s. Mix the alcohol, glycerin, and water, moisten the powdered calumba with the mixture, pack in a close vessel, and set aside to macerate for 6 hours; then pack in a glass funnel prepared for percolation, and gradually pour upon it the remainder of the menstruum, and, when this has passed from the surface, continue the percolation with dilute alcohol until 32 fluidounces of tincture are obtained. (*Druggists' Circular*, May, 1877.)

390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Extract of Indian Hemp, 1 *ounce* (Imperial) or 50 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Dissolve the Extract of Indian Hemp in *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of the Alcohol; filter if necessary; add sufficient of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The American reader must take care not to confound the Indian Hemp here referred to with *Apocynum cannabinum*, known by the same name in this country. The term "Indian Hemp" should be dropped entirely, as its continued use has been the cause of at least one fatal mistake. The strength of the present tincture is about 5 per cent. less than that of the 1880 tincture. The dose is from fifteen to thirty minims (0·9 to 1·9 C.c.), or about fifty drops, to be gradually increased till some effects are experienced.

TINCTURA CANTHARIDIS. U. S., Br. Tincture of Cantharides.

(TĬNC-TŪ'RĄ CĄN-THĂR'Į-DĬS.)

Tincture of Spanish Flies; Tinctura Cantharidum, *P. G.;* Teinture de Cantharides, *Fr.;* Spanischfliegentinktur, *G.*

"Cantharides, in No. 60 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Cantharides, in No. 40 powder, ¼ *ounce* (Imperial) or 12·5 grammes; Alcohol (90 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

An improvement was made in this tincture in the 1880 revision by substituting alcohol for diluted alcohol. It is frequently used in mixtures of castor oil and alcohol in the so-called hair tonics, and when made with diluted alcohol turbidity results. The official tincture is slightly stronger than that of the U. S. P. 1870. It is the most convenient form for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) If made with diluted alcohol, when long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. (Ménière, *Journ. de Pharm.*, Avril, 1861, p. 289.) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tincture is too feeble, containing the virtues of only 0·68 of a grain of cantharides in a fluidrachm. The dose of the U. S. tincture is from three to ten drops (0·09–0·30 C.c.), repeated three or four times a day.

TINCTURA CAPSICI. U. S., Br. Tincture of Capsicum. [Tincture of Cayenne Pepper.]

(TĬNC-TŪ'RĄ CĂP'SĮ-CĪ.)

Teinture de Piment des Jardins, *Fr.;* Spanischpfeffertinktur, *G.*

"Capsicum, in No. 30 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims] of Alcohol to *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Water. Having moistened the powder with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of the menstruum, pack it firmly in a cylindrical percolator; then gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Capsicum, in No. 20 powder, 1 *ounce* (Imperial) or 50 grammes; Alcohol (70 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture is slightly stronger than that of the U. S. P. 1870, and has been improved by the substitution of alcohol for diluted alcohol, as suggested by G. W. Kennedy (*A. J. P.*, March, 1876) and others. It is a useful stimulant in *very low states of the system* with gastric insensibility, as in *malignant scarlet* and *typhus fevers*, and in the cases of drunkards. It may also be used, diluted with water, as a gargle. (See *Capsicum.*) Applied by means of a camel's-hair pencil to the *relaxed uvula*, it sometimes produces contraction and relieves prolapsus of that part. The dose is from ten to fifteen minims (0·3 to 0·9 C.c.).

TINCTURA CARDAMOMI. U. S. Tincture of Cardamom.

(TĬNC-TŪ'RĄ CĂR-DĄ-MŌ'MĪ.)

Teinture de Cardamome, *Fr.;* **Kardamomentinktur,** *G.*

"Cardamom, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture is an agreeable but strong aromatic, and may be advantageously added to tonic and purgative infusions. The dose is one fluidrachm (3·7 C.c.).

TINCTURA CARDAMOMI COMPOSITA. U. S., Br. Compound Tincture of Cardamom.

(TĬNC-TŪ'RĄ CĂR-DĄ-MŌ'MĪ CỌM-PŎṢ'Ị-TĄ.)

Teinture de Cardamome composée, *Fr.;* **Zusammengesetzte Kardamomentinktur,** *G.*

"Cardamom, *twenty grammes* [or 309 grains]; Cassia Cinnamon, *twenty grammes* [or 309 grains]; Caraway, *ten grammes* [or 154 grains]; Cochineal, *five grammes* [or 77 grains]; Glycerin, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Cardamom, Cinnamon, Caraway, and Cochineal, and reduce them to a moderately coarse (No. 40) powder. Having moistened the powder with *twenty-five cubic centimeters* [or 406 minims] of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims] of Tincture are obtained; then add the Glycerin, and mix them." *U. S.*

"Cardamom Seeds, bruised, ½ *ounce* (Imperial) or 12·5 grammes; Caraway Fruit, bruised, ½ *ounce* (Imp.) or 12·5 grammes; Raisins of commerce, freed from seeds, 2 *ounces* (Imp.) or 100 grammes; Cinnamon Bark, bruised, ½ *ounce* (Imp.) or 25 grammes; Cochineal, in powder, 55 *grains* or 6·3 grammes; Alcohol (60 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This is a very agreeable aromatic tincture, occasionally used as a carminative in the dose of one or two fluidrachms (3·7 or 7·5 C.c.), but more frequently as an addition to mixtures, infusions, etc., which it renders pleasant to the taste and acceptable to the stomach. The substitution of honey in the U. S. formula of 1870 for the raisins in that of 1850 was an improvement, as it facilitated the process and gave more precision to the result; but a still greater improvement was made in the process of 1880 in the substitution of glycerin, which increases the stability of the preparation and takes the place of a liquid which is usually found adulterated in commerce.

TINCTURA CASCARILLÆ. Br. Tincture of Cascarilla.

(TĬNC-TŪ'RĄ CĂS-CĄ-RĬL'LÆ.)

Teinture de Cascarille, *Fr.;* **Kaskarilltinktur,** *G.*

"Cascarilla, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with *three fluid ounces* (Imp. meas.) or one hundred and fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture has the properties of cascarilla, but is seldom if ever used in this country. The dose is from thirty minims to two fluidrachms (1·9–7·5 C.c.).

TINCTURA CATECHU COMPOSITA. U. S. (Br.) Compound Tincture of Catechu.

(TĬNC-TŪ'RĄ CĂT'Ẹ-ȼHŪ CỌM-PŎṢ'Ị-TĄ.)

Tinctura Catechu, *Br.;* **Teinture de Cachou,** *Fr.;* **Katechutinktur,** *G.*

"Catechu, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Cassia Cinnamon, in No. 40 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powders, and, without moistening, pack the mixture firmly in a cylindrical percolator; then gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

" Catechu, in coarse powder, 4 *ounces* (Imperial) or 200 grammes; Cinnamon Bark, bruised, 1 *ounce* (Imp.) or 50 grammes; Alcohol (60 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

The name of this tincture was changed at the 1880 revision, so that it more accurately indicates its composition than did its former name. Cinnamon has been present in the tincture of catechu of former Pharmacopœias in the same relatively large proportion,—2 parts of cinnamon to 3 parts of catechu,—and this disproportion has been usually overlooked. The present tincture contains 2 parts of catechu to 1 part of cinnamon. The British tincture (1898) was increased 60 per cent. in the proportion of catechu. This is a grateful astringent tincture, useful in all cases to which catechu is applicable and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in *diarrhœa*. The dose is from thirty minims to three fluidrachms (1·9–11·25 C.c.), which may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contraindicated. It sometimes gelatinizes when kept, and becomes unfit for use.

TINCTURA CHIRATÆ. U. S., Br. Tincture of Chirata.

(TĬNC-TŪ'RĄ ȻHĮ-RĀ'TÆ.)

Tincture of Chiretta; Teinture de Chirette, *Fr.;* Chirettatinktur, *G.*

" Chirata, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

" Chiretta, in No. 40 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a tonic tincture which was introduced for the first time by the U. S. P. 1880, but which even before then had been largely used in some sections of our country. The British tincture (1898) was decreased in strength 20 per cent., and is now uniform with the U. S. tincture. The dose is from one to two fluidrachms (3·7–7·5 C.c.), three or four times a day.

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITÆ. Br. Compound Tincture of Chloroform and Morphine.

(TĬNC-TŪ'RĄ ȻHLŌ-RŌ-FÖR'MĪ ĔT MÖR-PHĪ'NÆ CǪM-PŎŞ'Ị-TÆ.)

" Chloroform, 1½ *fl. ounces* (Imperial measure) or 75 cubic centimetres; Morphine Hydrochloride, 87½ *grains* or 10 grammes; Diluted Hydrocyanic Acid, 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Tincture of Capsicum, ½ *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Tincture of Indian Hemp, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Oil of Peppermint, 14 *minims* or 1·5 cubic centimetres; Glycerin, 5 *fl. ounces* (Imp. meas.) or 250 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Chloroform, Tincture of Capsicum, Tincture of Indian Hemp, Oil of Peppermint, and Glycerin with *nine fluid ounces* (Imp. meas.) or four hundred and fifty cubic centimetres of the Alcohol, and dissolve the Morphine Hydrochloride in the mixture; add the Diluted Hydrocyanic Acid; then mix with enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Compound Tincture. This preparation contains in a ten-minim dose ¾ minim of Chloroform, ½ minim of Diluted Hydrocyanic Acid, and $\frac{1}{11}$ grain of Morphine Hydrochloride,—that is, more than four times the proportion of Morphine Hydrochloride present in the corresponding preparation of the British Pharmacopœia of 1885." *Br.*

This is the official substitute for chlorodyne, the well-known British nostrum. It differs not only in strength (see above) from the preparation formerly official, but is now transparent. The dose is from five to ten minims (0·31–0·62 C.c.). (See also *Mistura Chloroformi et Opii*, National Formulary, PART II., and *Chlorodyne*, p. 383.)

TINCTURA CIMICIFUGÆ. U. S., Br. Tincture of Cimicifuga.

(TĬNC-TŪ'RĄ CĬM-Ị-CĬF'Ū-ĢÆ.)

Tinctura Actææ; Tincture of Actæa.

"Cimicifuga, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Cimicifuga, in No. 40 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture is inferior to the fluid extract, because the medical powers of the menstruum are almost equal to those of the drug, although dissimilar. The strength of the British tincture (1898) was injudiciously decreased 20 per cent., and it is now only half that of the U. S. tincture. The dose is from a fluidrachm to half a fluidounce (3·7–15 C.c.).

TINCTURA CINCHONÆ. U. S., Br. Tincture of Cinchona.

(TĬNC-TŪ'RĄ CĬN-ĢHŌ'NÆ.)

Tincture of Yellow Cinchona; Tincture of Peruvian Bark; Tinctura Chinæ, *P. G.*; Teinture de Quinquina, *Fr.*; Chinatinktur, *G.*

"Cinchona, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Glycerin, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with *six hundred and seventy-five cubic centimeters* [or 22 fluidounces, 396 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the menstruum, macerate for twenty-four hours; then pack it firmly in a cylindrical glass percolator, and pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of Alcohol and Water, made in the same proportions as before, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Red Cinchona Bark, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powdered Bark with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol; set aside for twenty-four hours in a closed vessel; percolate with more of the Alcohol, until *fourteen fluid ounces* (Imp. meas.) or seven hundred cubic centimetres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter.

"Take ten cubic centimetres of the resulting strong tincture, and determine its proportion of alkaloids by the assay process given under 'Extractum Cinchonæ Liquidum.'

"Add to the bulk of the strong tincture such a quantity of the Alcohol that one hundred cubic centimetres of the resulting Tincture shall contain one gramme of alkaloids. Ten cubic centimetres, when treated by the assay process described under 'Extractum Cinchonæ Liquidum,' should yield an amount of alkaloids representing not less than 0·95 gramme nor more than 1·05 grammes, in one hundred cubic centimetres of the Tincture." *Br.*

This tincture is very properly made with a large proportion of bark, as in the bitter tinctures it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of the Br. Ph. 1898 is now made from 70 per cent. alcohol instead of the old menstruum 50 per cent., and is assayed so that it has a definite strength (100 C.c. containing 1 Gm. of alkaloids); these are undoubted improvements. (*Chem. and Drug.*, 1892, 325.) A deposit is apt to form in the tincture when kept, consisting chiefly of cinchonic red holding probably a portion of the alkaloids in combination. This was found by Mr. J. Adams to be perfectly dissolved by heat, though it uniformly reappeared on the cooling of the tincture. The addition of diluted sulphuric acid did not cause its solution; and, even though it was removed by filtering the tinc-

ture, the deposition was afterwards renewed. (*P. J. Tr.*, April, 1868, 470.) In reference to a mode of obviating in some measure this tendency to deposition, the reader is referred to the statements of M. Vaufiart on the subject of deposition in the tinctures prepared by percolation. Mr. A. B. Taylor, in experimenting on this subject, prepared a tincture in which the menstruum consisted of two parts of alcohol, one part of water, and one part of glycerin, and which was kept three months without undergoing deposition. (*A. J. P.*, Jan. 1865, 50.) This suggested the addition of glycerin to the official formula, and there can be no doubt that the tincture has been thereby improved, experience having demonstrated the utility of glycerin in liquid preparations of cinchona. Tincture of cinchona is rarely employed, but may be used as a tonic in doses of from one to four fluidrachms (3·7–15 C.c.).

TINCTURA CINCHONÆ COMPOSITA. U. S., Br. Compound Tincture of Cinchona.

(TĬNC-TŪ'RĄ CĬN-ØHŌ'NÆ CǪM-PǑṢ'Į-TĄ.)

Compound Tincture of Peruvian Bark; Tinctura Chinæ Composita, *P. G.*; Huxham's Tincture of Bark; Teinture de Quinquina composée, Elixir fébrifuge d'Huxam, *Fr.*; Zusammengesetzte Chinatinktur, *G.*

"Red Cinchona, *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, *eighty grammes* [or 2 ounces av., 360 grains]; Serpentaria, *twenty grammes* [or 309 grains]; Glycerin, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of Alcohol and *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims] of Water. Having mixed the Cinchona, Orange Peel, and Serpentaria, reduce them to a fine (No. 60) powder. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical glass percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of Alcohol and Water, made in the same proportions as before, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Dried Bitter-Orange Peel, well bruised, 1 *ounce* (Imperial) or 50 grammes; Serpentary Rhizome, in No. 40 powder, ½ *ounce* (Imp.) or 25 grammes; Cochineal, in powder, 28 *grains* or 3·2 grammes; Saffron, 55 *grains* or 6·3 grammes; Tincture of Cinchona, 10 *fl. ounces* (Imp. meas.) or 500 cubic centimetres; Alcohol (70 per cent.), *a sufficient quantity*. Mix the solid ingredients with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside in a closed vessel for seven days, agitating frequently; strain; press the marc; mix the liquids; add the Tincture of Cinchona, and enough of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Compound Tincture; set aside for twenty-four hours; filter. 10 cubic centimetres, when treated by the assay process described under 'Extractum Cinchonæ Liquidum,' should yield not less than 0·045 gramme nor more than 0·055 gramme of alkaloids. 2 cubic centimetres of the Compound Tincture after evaporation should leave a residue which imparts a yellow color to *chloroform*." *Br.*

This is the preparation commonly known by the name of *Huxham's tincture of bark*. It differs from that official in the U. S. P. 1870 principally in the alcoholic strength of the menstruum, which is now about in the proportion of 11 volumes of alcohol to 1 volume of water; it was formerly 3 volumes of alcohol to 1 volume of water. The use of glycerin is an improvement, precipitation being thus largely prevented. It will be observed that the drugs are not directed in the powdered state, the intention being to mix the drugs together and then to reduce the mixture to a *uniform* powder; in this way the volatile principles in the Serpentaria and Orange Peel are retained, and thorough exhaustion by percolation is secured. The process for the British tincture (1898) presents some novel features. Half of the quantity of the tincture is first made from four of the ingredients; this is then mixed with an equal bulk of tincture of cinchona. The reason for this is probably to avoid assaying a mixed product during the process; but the final test has to deal with the finished tincture, and the utility of the whole method is doubtful. The U. S. plan of using assayed cinchona bark, and then exhausting all of the ingredients by percolation, is simpler and just as efficient. Compound tincture of cinchona is an excellent stomachic cordial tonic, too feeble, however, in the principles of cinchona to serve as a substitute for the alkaloids when a full effect is required. The dose is from one to four fluidrachms (3·7–15 C.c.).

TINCTURA CINNAMOMI. U. S., Br. Tincture of Cinnamon.

(TĬNC-TŪ'RĄ CĬN-NĄ-MŌ'MĪ.)

Teinture de Cannelle, *Fr.;* Zimmttinktur, *G.*

"Ceylon Cinnamon, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycerin, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water. Having moistened the powder with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of the menstruum, pack it in a conical percolator, gradually pour on the remainder of the menstruum, and afterwards more of a mixture of Alcohol and Water, made in the same proportions as before, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Cinnamon Bark, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The British tincture (1898) was increased 60 per cent. in the proportion of cinnamon, and it is now twice the strength of the U. S. preparation. This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures and astringent infusions or decoctions. By long keeping it is apt to gelatinize and become unfit for use. According to Mr. Greenish, this can be prevented by using a menstruum composed of six parts of alcohol and two parts of water. (*P. J. Tr.*, Feb. 1872, 641.) The dose is from one to three or four fluidrachms (3·7–11·25 or 15 C.c.). It forms an agreeable flavoring to other tinctures.

TINCTURA COCCI. Br. Tincture of Cochineal.

(TĬNC-TŪ'RĄ CŎC'ÇĪ.)

Teinture de Cochenille, *Fr.;* Cochenilletinktur, *G.*

"Cochineal, in powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (45 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This is valued chiefly for imparting color to liquid preparations. It may, however, be given internally in nervous affections in doses of from twenty drops to a fluidrachm (1·25–3·7 C.c.).

TINCTURA COLCHICI SEMINIS. U. S. (Br.) Tincture of Colchicum Seed.

(TĬNC-TŪ'RĄ CŎL'ÇHĮ-CĪ SĔM'Į-NĬS.)

Tinctura Colchici Seminum, *Br.;* Tinctura Colchici, *U. S.* 1880; Tincture of Colchicum Seeds; Teinture de Semences de Colchique, *Fr.;* Zeitlosentinktur, *G.*

"Colchicum Seed, in No. 30 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, macerate for twenty-four hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Colchicum Seeds, in No. 30 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with rather more than one and a half times the proportion of Colchicum Seeds ordered for the corresponding preparation in the British Pharmacopœia of 1885." *Br.*

It was at one time supposed that the tincture was quite as effective made from the unbruised as from the bruised seeds; but the opinion has been shown to be erroneous. (*A. J. P.*, xxvi. 120.) See also a paper by Mr. N. Rosenwasser, *Ibid.*, 1877, 436. Subsequently Mr. L. I.

Morris showed that if the whole seeds were *digested* with hot diluted alcohol they could be perfectly exhausted. (*A. J. P.*, 1881, p. 6.) Prof. Maisch recommends, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar, taking care that none of the menstruum or of the seeds should be wasted. (*Ibid.*, xxviii. 514.)

This tincture possesses the properties of colchicum, and may be given whenever that medicine is indicated; but the wine, containing less alcohol, is generally preferred. The dose is from fifteen minims to one fluidrachm (0·9–3·7 C.c.), to be repeated with caution.

TINCTURA CONII. Br. Tincture of Conium.

(TĬNC-TŪ'RĄ CŌ-NĪ'Ī.)

Tinctura Conii Fructus, *Br.* 1874; Tincture of Hemlock Fruit; Teinture de Ciguë, *Fr.;* Schierlingstinktur, *G.*

"Conium Fruit, recently reduced to No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was not admitted to the U. S. P. 1890; the formula of the tincture official in 1880 is appended.* The British tincture (1898) was increased 60 per cent. in strength over the tincture of the Br. Ph. 1885. A strong odor of coniine should be emitted by the tincture upon the addition of potassa. M. Ménière states that it lets fall, on standing, a yellow miliary deposit, resembling drops of oil, the form of which is modified under pressure. According to the experiments of Dr. John Harley, of London (*P. J. Tr.*, Jan. 1867, 414), the British tincture is an uncertain preparation, two fluidounces of it sometimes failing to produce any effect. The U. S. P. 1880 tincture is, however, about 30 per cent. stronger than the British, and cannot be considered inert if care be taken to select the conium fruit properly. The commencing dose is thirty minims (1–9 C.c.), to be increased if necessary.

TINCTURA CROCI. U. S., Br. Tincture of Saffron.

(TĬNC-TŪ'RĄ CRŌ'CĪ.)

Teinture de Safran, *Fr.;* Safrantinktur, *G.*

"Saffron, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the Saffron with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Saffron, 1 *ounce* (Imperial) or 50 grammes; Alcohol (60 per cent.), *one pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture possesses all the properties of saffron, but is of little other use than to give color to mixtures. The dose is from one to three fluidrachms (3·7–11·25 C.c.).

TINCTURA CUBEBÆ. U. S., Br. Tincture of Cubeb.

(TĬNC-TŪ'RĄ CŪ-BĒ'BÆ.)

Tincture of Cubebs; Teinture de Cubèbes, *Fr.;* Kubebentinktur, *G.*

"Cubeb, in No. 30 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Cubebs, in powder, 4 *ounces* (Imperial), or 200 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic

* "Conium, in No. 30 powder, *one hundred and fifty parts* [or four and three-quarter ounces av.]; Diluted Hydrochloric Acid, *four parts* [or one fluidrachm]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand parts* [or two pints]. Moisten the powder with *forty-five parts* [or two fluidounces] of Diluted Alcohol, previously mixed with the Diluted Hydrochloric Acid, and macerate for twenty-four hours; then pack it moderately in a conical glass percolator, and gradually pour Diluted Alcohol upon it, until *one thousand parts* [or two pints] of Tincture are obtained." *U. S.*

centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The U. S. P. 1880 tincture was about 25 per cent. weaker than that of the U. S. P. 1870, a change which was very unfortunate, almost destroying any therapeutic value the preparation may have had. The U. S. P. 1890 tincture, which is double the strength of the former tincture, undoubtedly represents cubeb. The British tincture (1898) is 60 per cent. stronger than the one formerly official, and is now identical with the U. S. preparation. The dose is from one to two fluidrachms (3·7–7·5 C.c.)

TINCTURA DIGITALIS. U. S., Br. Tincture of Digitalis.

(TĬNC-TŪ′RĄ DĬJ-Ĭ-TĀ′LĬS.)

Tincture of Foxglove; Teinture de Digitale, *Fr.;* Fingerhuttinktur, *G.*

"Digitalis, in No. 60 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Digitalis Leaves, in No. 20 powder, 2½ *ounces* (Imperial) or 125 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these it is apt to be weak or inefficient. The expressed juice of the leaves, preserved by means of alcohol, prepared as the British Succi, would probably be found a powerful preparation. (See page 1306.) Tincture of digitalis possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. It is said by M. Ménière to deposit on standing a green oily matter, and some white lance-shaped crystals soluble in an excess of acid. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The present U. S. preparation is slightly stronger than that of 1870. The ordinary dose is from ten to twenty drops (0·6–1·25 C.c.), repeated two or three times a day, and increased if necessary, but with caution; a fluidrachm, representing about eight grains of digitalis, may be given on occasion as a single dose.

TINCTURA ERGOTÆ AMMONIATA. Br. Ammoniated Tincture of Ergot.

(TĬNC-TŪ′RĄ ĔR′GŌ-TÆ ĄM-MŌ-NĮ-Ā′TĄ.)

"Ergot, in No. 20 powder, 5 *ounces* (Imperial) or 250 grammes; Solution of Ammonia, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), *a sufficient quantity*. Mix the Solution of Ammonia with *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of the Alcohol; moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of this mixture, and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture; set aside for twenty-four hours; filter." *Br.*

This is a new official tincture of the Br. Ph. 1898; it differs from the tincture recommended by the British Pharmaceutical Conference in the use of solution of ammonia in place of aromatic spirit of ammonia. Dose, from one-half to one fluidrachm (1·9–3·7 C.c.).

TINCTURA FERRI CHLORIDI. U. S. (Br.) Tincture of Ferric Chloride.

(TĬNC-TŪ′RĄ FĔR′RĪ ȻHLŌ′RĮ-DĪ.)

"A hydro-alcoholic solution of Ferric Chloride [$Fe_2Cl_6 = 323{\cdot}98$] containing about 13·6 per cent. of the anhydrous salt, and corresponding to about 4·7 (4·69) per cent. of metallic iron." *U. S.*

Tinctura Ferri Perchloridi, *Br.;* Tincture of Chloride of Iron; Tinctura Ferri Muriatis; Tincture of Perchloride of Iron; Tincture of Muriate of Iron; Tinctura Ferri Sesquichloridi; Teinture de Perchlorure de Fer, *Fr.;* Eisenchloridtinktur, *G.*

"Solution of Ferric Chloride, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluid-

ounces, 390 minims]. Mix the Solution with enough Alcohol to make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Let the Tincture stand, in a closely-covered vessel, at least three months; then transfer it to glass-stoppered bottles, and keep it protected from light." *U. S.*

"Strong Solution of Ferric Chloride, 5 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Alcohol (90 per cent.), 5 *fl. ounces* (Imp. meas.) or 250 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Strong Solution of Ferric Chloride with the Alcohol; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

This tincture does not differ materially from that official in 1880, the change due to making one by weight and the other by volume, and the rounding of the figures, causing a difference in specific gravity,—the U. S. P. 1880 tincture having the sp. gr. 0·980 and the U. S. P. 1890 tincture that of 0·960, the latter thus being slightly weaker.

The U. S. formula of 1870 appeared, in respect to the precise method of proceeding, to be copied from that of Dr. Squibb, published in *A. J. P.* (1857, p. 290).* Iron wire was chosen as the form of iron to be used, because it is generally the purest. This, which was in very slight excess, was first treated with a portion of the hydrochloric acid, which formed with it ferrous chloride, with the escape of hydrogen, producing effervescence. The action was allowed to go on spontaneously until effervescence ceased, and was then aided by heat, which caused the saturation of the acid used. The solution being filtered, the remainder of the hydrochloric acid was added, and afterwards the nitric acid gradually, the liquid having been heated to the boiling point before the latter addition. The nitric acid was decomposed, with the escape of nitrous fumes producing effervescence, while, through the influence of a portion of its oxygen and the additional portion of hydrochloric acid, the ferrous chloride was converted into ferric chloride, the conversion being completed when the effervescence ceased and the previous green color had been changed to a reddish brown. The precise reactions by which these changes are effected have been explained elsewhere. (See *Ferri Chloridum*, page 607, and *Liquor Ferri Chloridi*, page 798.) In the revision of 1870 the process was divided into two parts, and a new preparation, *Liquor Ferri Chloridi*, introduced. When this is added to the alcohol, the latter reacts gradually with the acid, producing a small proportion of an ether which gives a peculiar flavor to the tincture and probably modifies in some degree its influence on the system. For this reason it is preferable to keep the tincture a year before dispensing, and the official direction is to keep it at least three months.

Properties. Tincture of ferric chloride is "a bright, brownish liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction. Specific gravity, about 0·960 at 15° C. (59° F.). The Tincture yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in nitric acid, with silver nitrate test-solution. After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide test-solution, showing the presence of some ferrous salt, due to reduction. If the iron be completely precipitated from a portion of the Tincture by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or dark-colored precipitate with hydrogen sulphide test-solution (absence of *zinc* or *copper*), nor should it leave a fixed residue on evaporation and gentle ignition (absence of *salts of the fixed alkalies*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute portion of the Tincture, the crystal should not become colored brown, nor should there be a brownish-black zone developed around it (absence of *nitric acid*). On diluting 1 C.c. of the Tincture with water to 12 C.c., and boiling, the liquid should remain clear (absence of *oxychloride*). If 1·12 (1·1176) Gm. of the Tincture be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 9·4 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.*† The tincture is decomposed by the

* This process of Dr. Squibb was given in a note in the eleventh edition of the U. S. Dispensatory, page 1052.

† Mr. J. C. Wharton has noticed in the tincture silky asbestos-like crystals, which he believes are due to an action of the acids upon the glass in which the drug is prepared. (*A. J. P.*, xlii. 107.) Dr. Battey believes these crystals to be calcium sulphate. (*Ibid.*, xlii. 207.)

alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and mucilage of acacia, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.*

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for the purposes to which the chalybeates generally are applied. It is somewhat diuretic, and acts as a slightly stimulant astringent upon the genito-urinary organs. It is very valuable in connection with tincture of cantharides in *gleet*, and is very largely used in *chronic Bright's disease*. In passive *hemorrhages from the uterus, kidneys*, and *bladder* it has been thought to act advantageously. It is the standard remedy in *erysipelas;* but in *scarlatina*, *diphtheria*, and *purulent infection of the blood* experience has shown it to be of very little value, and as a styptic it is inferior to the solution of the subsulphate. The dose of the U. S. tincture is from ten to thirty minims (0·6–1·9 C.c.), which may be gradually increased to one or even two fluidrachms (3·7 or 7·5 C.c.), two or three times a day. In acute febrile diseases, as *erysipelas*, the dose should be repeated every two hours. It is given well diluted, and is very prone to injure the teeth.

TINCTURA GALLÆ. U. S. Tincture of Nutgall.

(TĬNC-TŪ'RĄ GĂL'LÆ.)

Tinctura Gallarum, *P. G.;* Tincture of Galls; Teinture de Noix de Galle, *Fr.;* Galläpfeltinktur, *G.*

"Nutgall, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol. Pack the powder, without moistening it, in a conical glass percolator; then gradually pour upon it the menstruum, and, afterwards, Alcohol, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

The tincture of galls is powerfully astringent, but is more used as a test than as a medicine. The present official tincture is about one-third stronger than that of the U. S. P. 1870. When long kept, it ceases to evince the reactions of tannic acid, in consequence of the conversion of this into gallic acid. The dose is from one to three fluidrachms (3·7–11·25 C.c.).

TINCTURA GELSEMII. U. S., Br. Tincture of Gelsemium.

(TĬNC-TŪ'RĄ ĢĔL-SĔM'Ị-Ī.)

"Gelsemium, in No. 60 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

* *Bestuchef's tincture*, which is much used in Europe, is simply a solution of ferric chloride in a mixture of one measure of ether and three or four measures of alcohol. Fr. Mayer recommends that the ferric chloride should be prepared by passing chlorine through a solution of ferrous chloride, until a solution of potassium ferricyanide no longer produces a blue precipitate, and then evaporating by a water-bath. In this mode crystals of ferric chloride are obtained, one ounce of which is to be dissolved in twelve ounces of ether mixed with four times its bulk of alcohol. The solution may be rendered colorless, if desired, by exposure to the direct rays of the sun. (*N. Y. Journ. of Pharm.*, i. 233.) This decolorization, however, is effected by a chemical change which somewhat alters the character of the preparation. The ferric chloride becomes ferrous chloride by the loss of a portion of its chlorine, which, by abstracting hydrogen from the alcohol, becomes hydrochloric acid; and this reacts with unaltered alcohol to form hydrochloric ether.

Mr. A. Cushman recommends the following process for the above tincture. He first prepares the crystals of the sesquichloride by dissolving two ounces of iron filings in a mixture of eight fluidounces of hydrochloric acid and four of distilled water, then adding four fluidrachms of nitric acid, evaporating to a pellicle, and setting aside to crystallize. The crystals, having been washed in alcohol, and afterwards redissolved and crystallized, are to be dissolved in a mixture of two parts of alcohol and one of ether; the proportion being an ounce of the crystals to twelve fluidounces of the mixture. After solution, the liquid is to be filtered, and exposed for 48 hours to the direct rays of the sun. (*A. J. P.*, xxix. 461; from *Am. Med. Gaz.*)

Tasteless Tincture of Ferric Chloride. Mr. J. Creuse introduced this preparation. We have used the following formula for it. Solution of Ferric Chloride, U. S. P., 1 fluidounce; Citric Acid, 544 grains; Sodium Carbonate, 1000 grains, or q. s.; Water, distilled, 1 fluidounce; Alcohol, q. s. Dissolve the citric acid in the distilled water, and heat to the boiling point, gradually adding the sodium carbonate until the acid is saturated. Mix this with the iron solution, which will now assume a beautiful green color, and make up the measure to 4 fluidounces with alcohol.

"Gelsemium Root, in No. 40 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture will prove a valuable addition, and will be preferred to the fluid extract for internal administration, as it is safer, and can be used more satisfactorily in extemporaneous combination. The menstruum of the U. S. P. 1890 process is weaker than that formerly official, alcohol having been replaced by alcohol diluted with water in the proportion of 65 to 35. For Farr and Wright's method of estimating this tincture, see *Chem. and Drug.*, 1892, 263. The dose is from ten to twenty minims (0·6–1·25 C.c.).

TINCTURA GENTIANÆ COMPOSITA. U. S., Br. Compound Tincture of Gentian.

(TĬNC-TŪ'RĄ ĢĔN-TĮ-Ā'NÆ CǪM-PǑṢ'Į-TĄ.)

"Gentian, *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, *forty grammes* [or 1 ounce av., 180 grains]; Cardamom, *ten grammes* [or 154 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Gentian, Orange Peel, and Cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix Alcohol and Water in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of menstruum, macerate for twenty-four hours; then pack it in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Gentian Root, cut small and well bruised, 2 *ounces* (Imperial) or 100 grammes; Dried Bitter-Orange Peel, well bruised, ¾ *ounce* (Imp.) or 37·5 grammes; Cardamom Seeds, bruised, ¼ *ounce* (Imp.) or 12·5 grammes; Alcohol (45 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

An improvement has been made in the process for this tincture, in directing the drugs to be mixed and powdered together: the pulverization is facilitated, and the odorous principles of the cardamom and orange peel are absorbed by the gentian. As compared with the U. S. P. 1880 tincture, the menstruum has been strengthened slightly, three volumes of alcohol and two of water being used in place of diluted alcohol, making a more permanent tincture; the proportion of cardamom has been reduced one-half, and that of gentian slightly increased. This is an elegant bitter, much used in *dyspepsia*, and as an addition to tonic mixtures in debilitated states of the digestive organs or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. Dose, one or two fluidrachms (3·7 or 7·50 C.c.).

TINCTURA GUAIACI. U. S. Tincture of Guaiac.

(TĬNC-TŪ'RĄ GUĀ'ĮĄ-CĪ—gwā'yą-sī.)

Tinctura Guajaci, *P. G.*; Teinture de Résine de Gaïac, *Fr.*; Guajaktinktur, *G.*

"Guaiac, in coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powder with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and macerate for seven days, in a closed vessel; then filter through paper, adding, through the filter, enough Alcohol to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

Although this tincture can be prepared by percolation if care and skill are used, maceration is doubtless preferable.

This tincture is given in *chronic rheumatism* and *gout*, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which the late Dr. Dewees found very efficient in the cure of *suppression of the menses* and *dysmenorrhœa*. "Take of the best Guaiac, in powder, *four ounces;* Carbonate of Soda or of Potassa *one drachm and a half;* Pimenta, in powder, *an ounce;* Diluted Alcohol *a pint*. Digest for a few days." Dr. Dewees directed a drachm or two of the spirit of ammonia to be added, *pro re nata*, to four fluidounces of the tincture. (*Treatise on Diseases of Females*, 1826, page 81.) The dose is a teaspoonful (3·7 C.c.) three times a day, to be gradually increased if necessary. The quantity

of alkaline addition is too small to produce any other effect than to render the resin more soluble, whilst the pimenta can act only as a spice: so that the virtues of the tincture reside in the guaiac, and the official ammoniated tincture is probably equally effectual. Prof. Ed. Schär recommends tincture of guaiac as a reagent to detect the presence of ozonizing bodies. (*Pharm. Rund.*, 1894, 254.)

TINCTURA GUAIACI AMMONIATA. U. S., Br. Ammoniated Tincture of Guaiac.

(TĬNC-TŪ'RĄ GUĀ'ĮĄ-CĪ ĄM-MŌ-NĮ-Ā'TĄ.)

Tinctura Guaiaci Composita; Teinture de Gaïac ammoniacale, *Fr.*; Ammoniakalische Guajaktinktur, *G.*

"Guaiac, in coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Aromatic Spirit of Ammonia, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powder with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Aromatic Spirit of Ammonia, and macerate for seven days in a closed vessel; then filter through paper, in a well-covered funnel, and add, through the filter, Aromatic Spirit of Ammonia, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Guaiacum Resin, in powder, 4 *ounces* (Imperial) or 200 grammes; Oil of Nutmeg, 30 *minims* or 3·1 cubic centimetres; Oil of Lemon, 20 *minims* or 2·1 cubic centimetres; Strong Solution of Ammonia, 1½ *fl. ounces* (Imp. meas.) or 75 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Strong Solution of Ammonia with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; add the Guaiacum Resin; set aside in a closed vessel for forty-eight hours, shaking frequently; filter; dissolve the Oil of Lemon and Oil of Nutmeg in the filtrate, and pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The British Pharmacopœia 1898 improved the process for this tincture by abandoning the distilled aromatic spirit of ammonia used as a menstruum by the former British authority and substituting alcohol containing solution of ammonia and volatile oils, the proportion of oil of lemon having been reduced 60 per cent.

This tincture is celebrated in the treatment of *chronic rheumatism*, and is frequently also used in *amenorrhœa*. It is more stimulating, and is probably more effectual, than the preceding, on account of the presence of the alkali. It is precipitated by water, and should be administered emulsified with gum, so that the guaiac may be held in suspension. The dose is from one to two fluidrachms (3·75–7·5 C.c.).

TINCTURA HAMAMELIDIS. Br. Tincture of Hamamelis.

(TĬNC-TŪ'RĄ HĂM-Ą-MĔL'Į-DĬS.)

"Hamamelis Bark, in No. 20 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The dose is from two to sixty minims (0·123–3·7 C.c.).

TINCTURÆ HERBARUM RECENTIUM. U. S. Tinctures of Fresh Herbs.

(TĬNC-TŪ'RÆ HĔR-BĀ'RŬM RĘ-CĔN'TĮ-ŬM.)

"These Tinctures, when not otherwise directed, are to be prepared by the following formula: Take of The Fresh Herb, bruised or crushed, *five hundred grammes* [or 17 ounces av., 279 grains]; Alcohol, *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Macerate the Herb with the Alcohol for fourteen days; then express the liquid and filter." *U. S.*

This is a general formula introduced for the guidance of the pharmacist in securing some degree of uniformity in this class of tinctures. Tinctures from fresh herbs are coming into use to some extent, and the fresh herb is to be preferred to the dried drug where a very volatile or easily dissociated substance is the active principle. It is evident that the relative strength must vary, however, with the degree of freshness of the drug and the amount of water contained in it, which depends upon the time of collection, the state of the weather when the herb was gathered, and the amount of subsequent exposure to the atmosphere: hence an absolutely uniform relation cannot be obtained. It is asserted that the fresh tinctures of thuja and gelsemium are more active than the tinctures from the dried drug. (*Proc. A. P. A.*,

1878, 755.) Dr. F. J. B. Quinlan preserves medicinal plants in a fresh state for a reasonable period in the following manner. The herbs in a perfectly fresh state are bruised to a pulp in a mortar, placed into a glass bottle, and well tamped down; the stopper is then forced in so as to exclude every particle of air, and the top encased by beeswax softened by heat. The bottles are then buried in the ground at a depth of three feet. So treated, belladonna, conium, and other herbs have been kept for four months perfectly sweet and fit for pharmaceutical purposes; and it is probable that bottled herbs will keep in this manner for six or even eight months, and perhaps longer. (*Year-Book of Pharmacy*, 1883, p. 491.)

TINCTURA HUMULI. U. S. (Br.) Tincture of Hops.

(TĬNC-TŪ'RĄ HŪ'MŬ-LĪ.)

Tinctura Lupuli, *Br.;* Teinture de Houblon, *Fr.;* Hopfentinktur, *G.*

"Hops, well dried and in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Hops, 4 *ounces* (Imperial) or 200 grammes; Alcohol (60 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This is a tincture which might well have been omitted in the last revision of the Pharmacopœia: it has little to recommend it from either a therapeutical or a pharmaceutical point of view. The strength of the British tincture (1898) has been increased 60 per cent. The menstruum is also slightly stronger in alcohol.

By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages due to their light and bulky character. Yet it is well known that the narcotic virtues of hops are injured by a thorough drying. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is different in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is preferable.* According to M. Ménière, tincture of hops deposits, on standing, a yellow precipitate, and a large quantity of a white crystalline substance, which he thinks may be calcium malate.

Tincture of hops is tonic and narcotic, but little reliance can be placed upon it. It is sometimes useful in the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of *delirium tremens*. The dose is from one to three fluidrachms (3·7–11·25 C.c.).

TINCTURA HYDRASTIS. U. S., Br. Tincture of Hydrastis.

(TĬNC-TŪ'RĄ HĬ-DRĂS'TĮS.)

"Hydrastis, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Hydrastis Rhizome, in No. 60 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or

* *Tinctura Lupulinæ. Tincture of Lupulin. Teinture de Lupuline*, Fr.; *Lupulintinktur*, G. "Take of Lupulin *four troyounces*; Alcohol *a sufficient quantity*. Pack the Lupulin in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.* 1870.

This is much superior to the tincture of hops of the first U. S. Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, the tincture thus made must be of unequal strength,—an objection to which the tincture of hops, even as now prepared, is in some measure liable. Besides, the amount of lupulin contained in any quantity of hops upon which alcohol can conveniently act is too small in proportion to the alcohol to afford a tincture of the due strength. The tincture of lupulin is, therefore, greatly preferable. The dose is one or two fluidrachms (3·7 or 7·5 C.c.), to be given in sweetened water or some mucilaginous fluid. Under the name of *Ammoniated Tincture of Lupulin*, Dr. Dyce Duckworth proposes as the best preparation a tincture made by macerating for seven days two ounces of lupulin in a pint of aromatic spirit of ammonia, and then filtering. The dose is from half a fluidrachm to a fluidrachm (1·9–3·7 C.c.). (*A. J. P.*, xli. 416.)

one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture will probably prove useful in combination with other tinctures, or as an addition to extemporaneous mixtures where the fluid extract would not be so eligible. Dose, from one-half to one fluidrachm (1·9–3·75 C.c.).

TINCTURA HYOSCYAMI. U. S., Br. Tincture of Hyoscyamus.

(TĬNC-TŪ′RĄ HĬ-ǪS-CĬ′Ą-MĪ.)

Tincture of Henbane; Teinture de Jusquiame, *Fr.;* Bilsenkrauttinktur, *G.*

"Hyoscyamus, in No. 60 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Hyoscyamus Leaves and flowering tops, in No. 20 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The strength of the British tincture (1898) has been slightly reduced (20 per cent.) in order to bring it into the class of tinctures having the maximum dose of a fluidrachm.

This tincture possesses the activities of hyoscyamus.* When it purges, as it sometimes does, it may be united with a very small proportion of laudanum. The dose is a fluidrachm (3·75 C.c.). The expressed juice preserved by means of alcohol may be used for the same purposes as the tincture.

TINCTURA IODI. U. S., Br. Tincture of Iodine.

(TĬNC-TŪ′RĄ Ī-Ō′DĪ.)

Tinctura Iodinii, *Pharm.* 1870; Tinctura Iodi, *P. G.;* Teinture d'Iode, *Fr.;* Jodtinktur, *G.*

"Iodine, *seventy grammes* [or 2 ounces av., 205 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Triturate the Iodine rapidly, in a mortar, to a coarse powder, and transfer it at once to a graduated bottle. Rinse the mortar with several successive portions of Alcohol, and pour the rinsings into the bottle. Then add Alcohol, shaking the bottle occasionally, until the Iodine is dissolved, and the finished Tincture measures *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Iodine, ½ *ounce* (Imperial) or 25 grammes; Potassium Iodide, ½ *ounce* (Imp.) or 25 grammes; Distilled Water, ½ *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Place the Iodine and Potassium Iodide in a bottle with the Distilled Water; when solution has been effected, add a sufficient quantity of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. If 10 cubic centimetres of the Tincture be diluted with 20 cubic centimetres of *water*, it should require, for complete decoloration, 19·6 cubic centimetres of the *volumetric solution of sodium thiosulphate*." *Br.*

The process of the U. S. P. 1890 is an improvement in manipulation over that of the former Pharmacopœias, where the saving of time is an object. The iodine in the quantity directed in the formula makes nearly a saturated solution, and by coarsely powdering it, as directed, the solution is greatly facilitated; when the operator has no necessity for dissolving the iodine rapidly, it may simply be placed in the bottle with the solvent and allowed to dissolve slowly. The British tincture is much weaker than that of the U. S. P., the latter being 2·8 times stronger than the British, which also contains potassium iodide, added to increase the solubility of the iodine, so that it shall not be precipitated when added to water; this result is only partially effected, and it was deemed best not to introduce potassium iodide into the simple tincture of iodine of the U. S. P. 1880, and to omit the compound tincture of iodine of the U. S. P. 1870,† as it was frequently mistaken for the compound solution, and there was no necessity

* According to M. Donovan, the tincture when made of leaves of only one year's growth is inert. (*P. J. Tr.*, 1871, p. 907.)

† *Tinctura Iodinii Composita.* U. S. 1870. *Compound Tincture of Iodine.* "Take of Iodine *half a troyounce;* Iodide of Potassium *a troyounce;* Alcohol *a pint.* Dissolve the Iodine and Iodide of Potassium in the Alcohol." The compound tincture of iodine may be given internally for all the purposes which iodine is capable of answering. The dose is from fifteen to thirty drops (0·9–1·9 C.c.), to be gradually increased if necessary.

for having both official. The compound solution of iodine is retained, and is most suitable for internal administration. (See *Liquor Iodi Compositus.*) It is best to prepare the tincture in small quantities at a time, as the iodine reacts with the alcohol, giving rise to chemical changes. The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stoppered bottles, in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

Tincture of iodine has a deep brown color. One grain of iodine is contained in about fifteen minims, or thirty drops. "If 6·3 C.c. of the Tincture be mixed with a solution of 2 Gm. of potassium iodide in 25 C.c. of water, and a little starch test-solution added, it should require, for complete decoloration, about 35 C.c. of sodium hyposulphite decinormal volumetric solution (corresponding to about 7 Gm. of iodine in 100 C.c)." *U. S.* It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture, and it is supposed that when this is swallowed the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when kept, owing, according to Guibourt, to a reaction between the alcohol and the iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which dissolves another portion of the iodine to form iodized hydriodic acid, while the place of the hydrogen in the alcohol is supplied by iodine, giving rise to ethyl iodide and similar products. The new products have an agreeable odor and are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. Dr. A. Göpel found the change to be so slow, when the tincture is kept in the dark and at a low temperature, that in three months a specimen thus treated had lost but one per cent. of iodine. (*Pharm. Centralbl.*, No. 13, 1850.) M. Commaille, in 1859, confirmed the labors of the last-mentioned investigator. Subsequent experiments have, however, given results somewhat at variance with those of Guibourt. M. Carles found that after exposure in a transparent glass flask to diffuse daylight for ten months, the tincture contained only one-twelfth per cent. of hydriodic acid. He was also unable to find any of the ethyl iodide which, according to Guibourt, is formed simultaneously with the acid. (*P. J. Tr.*, 3d ser., v. 88.) On account of its liability to precipitation in the stomach, the tincture of iodine is now employed locally almost exclusively. Locally used, if undiluted, it acts as a powerful irritant to the skin, producing inflammation, desquamation of the cuticle, etc. Nevertheless, it is much used in this state in *erysipelas*, *chilblains*, and other cases of *cutaneous and subcutaneous inflammation*, and with happy effects. But its application requires some caution; and in erysipelas it is better to surround the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than to attempt a complete cure by covering the whole surface affected. It has been found useful in rendering the *variolous eruption* abortive. It is most conveniently applied by means of a camel's-hair pencil. Diluted with camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in *scrofulous tumors* and other affections requiring the use of iodine. It is much used in the radical cure of *hydrocele*, as an injection into the sac; and a similar employment of it has been extended to other serous cavities morbidly distended with fluid, as in *ovarian dropsy*, *ascites*, and *empyema;* but in these latter affections it should be resorted to, if at all, with great caution. In hydrocele, M. Velpeau employed it diluted with double its volume of water. In the other cases referred to, it has been variously diluted with from three to ten times its bulk of water or some demulcent liquid. The *Tinctura Iodi Decolorata* of the German Pharmacopœia 1872 is made by digesting at a gentle heat ten parts, each, of iodine, sodium hyposulphite, and distilled water until solution is effected, adding sixteen parts of spirit of ammonia, shaking for a few moments, then adding seventy-five parts of alcohol, allowing the mixture to stand for three days in a cool place, and filtering. This preparation, and all similar ones having this name, are calculated to mislead practitioners, for they contain no free iodine, but are variable mixtures, consisting principally of ammonium iodide: the former German tincture contains in addition some ethyl iodide, triethyl-ammonium iodide, and traces of sodium iodide and sulphate.* M. Luc

* *Tinctura Iodi Decolorata. Colorless Tincture of Iodine.* Under this name a preparation is described by Dr. N. J. Aiken, of St. Louis, Mo., which is made by mixing equal measures of Compound Tincture of Iodine and Strong Water of Ammonia. The mixture in time becomes colorless, and, if not so at the end of 24 hours, more ammonia may be added, even to the extent of one-fourth if necessary. When wanted weak, it may be diluted to any desired extent by water or glycerin. In consequence of the chemical changes which take place, *it is no longer tincture of iodine*, but a hydro-alcoholic solution of potassium and ammonium iodides, with more or less ammonia and a trace of iodoform. It is recommended for external use whenever a discutient is required, and has been used for its revulsive

has found the inhalation of the fumes from the slightly warmed tincture very useful in *coryza*.

The dose of the tincture is from five to fifteen drops, but Lugol's solution is a much preferable preparation for the internal administration of iodine. M. Debauque, an apothecary of Mons, has ascertained that tannic acid has the property of rendering iodine soluble in water, and states that an ounce of syrup of orange-peel in four or six ounces of water will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*Journ. de Pharm.*, 3e sér., xx. 34.) Owing to the caustic effect of the iodine, and the coagulating action of the alcohol, where it is desired to get an absorption of iodine, as in the case of *enlarged glands*, a solution in glycerin or olive oil is preferable to the tincture. (See *Iodum*, page 748.)

TINCTURA IPECACUANHÆ ET OPII. U. S. Tincture of Ipecac and Opium.

(TĬNC-TŪ′RĄ ĬP-Ę-CĂC-Ŭ-ĂN′HÆ ĔT Ō′PĮ-Ī.)

"Tincture of Deodorized Opium, *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]; Fluid Extract of Ipecac, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Evaporate the Tincture of Deodorized Opium, in a tared capsule, on a water-bath, until it weighs *eight hundred grammes* [or 28 ounces av., 96 grains]. When it has become cold, add to it the Fluid Extract of Ipecac, filter the mixture, and pass enough Diluted Alcohol through the filter to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This tincture is intended to represent Dover's powder in a liquid form. Ten minims (0·6 C.c.), the adult dose, represent one grain of powdered opium and one grain of ipecac.

TINCTURA JABORANDI. Br. Tincture of Jaborandi.

(TĬNC-TŪ′RĄ JĂB-Ǫ-RĂN′DĪ.)

"Jaborandi Leaves, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation possesses no advantages over the fluid extract, but is undoubtedly efficient. The Br. Pharm. gives the dose as from one-half to one fluidrachm; but, as one drachm represents only eleven grains of the jaborandi, it is evident that from two to three fluidrachms (7·5–11·25 Gm.) in many cases will be necessary for any effect.

TINCTURA JALAPÆ. Br. Tincture of Jalap.

(TĬNC-TŪ′RĄ JĄ-LĀ′PÆ.)

Teinture de Jalap, *Fr.;* Jalapentinktur, *G.*

This tincture is no longer official in the U. S. Pharmacopœia. The tincture of jalap of the U. S. P. 1870 was made by percolating six troyounces of powdered jalap with a mixture of two measures of alcohol and one of water until two pints of tincture were obtained.

"Jalap, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol; pack in a percolator; gradually add more of the Alcohol until *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of percolate has been collected; subject the marc to pressure; add the expressed liquid to the percolate; set aside for twenty-four hours; filter. Determine the amount of Jalap Resin present in ten cubic

effects in inflammatory diseases, as *pneumonia* and *rheumatism*. It is recommended also topically in *erysipelas, furuncles, sprains, bruises,* and *neuralgic affections*. (*Am. J. Med. Sci.*, Oct. 1865, 398.) It is stated that on the addition of ammonia some nitrogen iodide is generally precipitated; and, as this is an explosive compound, caution is necessary. The deposit, however, disappears upon the completion of the decolorization. (*A. J. P.*, July, 1869.) Dr. Chas. O. Curtman gives the following formula (*A. J. P.*, xli. 364). Take of Iodine *one ounce and a quarter;* Alcohol *thirteen fluidounces;* Strong Water of Ammonia *three fluidounces*. Dissolve the Iodine in the Alcohol, and add the Ammonia. Allow to stand for four weeks, with occasional agitation, so that the precipitate may dissolve. A rapid preparation may be made by using an excess of ammonia, and afterwards adding, cautiously, hydrochloric acid until the reaction is only feebly alkaline. Mr. Jos. L. Macmillan finds that 5·3 decigrammes of a solution of caustic soda of sp. gr. 1·07 at 15·55° C. will decolorize 3·6 grammes of the tincture (*B. P.*). (*A. J. P.*, xliii. 360.)

centimetres of the resulting strong tincture by the process described under 'Jalapæ Resina,' and dilute the remainder of the strong tincture with a sufficient quantity of the Alcohol to produce a Tincture containing 1·5 grammes of the Resin in one hundred cubic centimetres. Treated as described under 'Jalapæ Resina,' 10 cubic centimetres of the Tincture should yield not less than 0·145 nor more than 0·155 gramme of the Resin." *Br.*

This tincture was increased in strength 60 per cent. at the last revision of the Br. Ph. 1898. It possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the dose of one or two fluidrachms (3·75 or 7·5 C.c.), to increase their activity.

TINCTURA KINO. U. S., Br. Tincture of Kino.

(TĬNC-TŪ'RA KĪ'NŌ.)

Teinture de Kino, *Fr.;* Kinotinktur, *G.*

"Kino, *one hundred grammes* [or 3 ounces av., 321 grains]; Glycerin, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Water, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Glycerin with the Water and *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol. Rub the Kino, in a mortar, adding gradually a sufficient quantity of the menstruum, until a smooth paste is produced. Transfer this to a bottle, add the remainder of the menstruum, and macerate for twenty-four hours, with occasional agitation. Then filter through paper, adding, through the filter, enough Alcohol to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Keep the Tincture in small, completely-filled and well-stoppered bottles, in a cool place." *U. S.*

"Kino, in powder, 2 *ounces* (Imperial) or 100 grammes; Glycerin, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Distilled Water, 5 *fl. ounces* (Imp. meas.) or 250 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Glycerin and the Distilled Water; rub the Kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder of the mixture; transfer to a closed vessel; add *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside for twelve hours, frequently agitating; filter through a plug of cotton wool; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

Much inconvenience is caused by the tendency of this tincture to gelatinize and gradually lose its astringency. The present official formula is believed to furnish a tincture free from objection: it is a slight modification of the process proposed by P. P. Fox (*A. J. P.*, June, 1877). A specimen in our possession made with the above menstruum successfully withstood exposure for three years, retaining its original limpid condition. It is probable that different specimens of kino vary in their tendency to gelatinize. Mr. Groves states that fresh kino will not gelatinize, and Mr. Martindale that the Australian kino is much more apt to do so than the East India drug. The character of the chemical reaction which takes place remains to be investigated. The air has some effect; for if this be entirely excluded the tincture will keep for a long time without undergoing the change. It should be introduced, when prepared, into very small bottles, which should be kept well corked and be opened only when wanted for use. Mr. J. D. Wood obtains a handsome preparation, which he believes to keep perfectly and not gelatinize, by using a menstruum of 2 parts of alcohol 0·835, and 1 part each of water and glycerin. L. Myers Connor gets rid of the gelatinizing property by using magnesium carbonate in making the tincture, but it is very probable that a large part of the kino-tannic acid is removed at the same time. (*A. J. P.*, xlv. 260.) Mr. P. F. Smith, of Louisville, furnishes the following formula. "Take of Kino *one ounce and a half;* Ground Logwood *half an ounce;* Diluted Alcohol *a sufficient quantity*. Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Diluted Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained." We have used this process and have not noticed gelatinization to take place in any instance. Sugar added in equal proportion with the kino employed has been recommended as a preventive of gelatinization, and R. Rother claims permanence for the following formula. Powder one and a half troyounces of kino and half a troyounce of catechu, mix them, add ten fluidounces of water, heat for ten or fifteen minutes with constant stirring, and let the mixture cool. Add water to make the mixture twelve fluidounces, and then add four fluidounces of alcohol. Pour the mixture into a bottle containing sixty grains of filter-paper, shake the whole well at intervals, and strain the tincture after twenty-four

hours. (*A. J. P.*, 1886, 333–336.) The dose of tincture of kino is one or two fluidrachms (3·75 or 7·5 C.c.). It is used chiefly as an addition to chalk mixtures in *diarrhœa*.

TINCTURA KRAMERIÆ. U. S., Br. Tincture of Krameria.

(TĬNC-TŪ′RĄ KRĄ-MĒ′RĮ-Æ.)

Tincture of Rhatany; Tinctura Ratanhæ, *P. G.;* Teinture de Ratanhia, *Fr.;* Ratanhatinktur, *G.*

"Krameria, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Krameria Root, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was increased in strength 60 per cent. at the last revision of the British Pharmacopœia (1898); it is stated that the tincture made from Pará rhatany furnishes a clear solution on the addition of water, while that from Peruvian root yields a turbid mixture.

The same precaution should be observed in keeping this tincture as is recommended for tincture of kino. It is a good preparation in cases which admit of the use of small quantities of alcohol. The dose is one or two fluidrachms (3·75 or 7·5 C.c.).

TINCTURA LACTUCARII. U. S. Tincture of Lactucarium.

(TĬNC-TŪ′RĄ LĂC-TŪ-CĀ′RĮ-Ī.)

"Lactucarium, *five hundred grammes* [or 17 ounces av., 279 grains]; Glycerin, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Water, Alcohol, Benzin, Diluted Alcohol, each, *a sufficient quantity*. Beat the Lactucarium in an iron mortar, with clean sand, to a coarse powder, and introduce it into a bottle; add *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of Benzin, cork the bottle tightly, and set it aside for forty-eight hours, frequently agitating the mixture. Pour the mixture on a double filter, and allow it to drain. Wash the residue by gradually adding *fifteen hundred cubic centimeters* [or 50 fluidounces, 345 minims] of Benzin. Allow the Lactucarium to dry by exposing it to a current of air. When it is dry, and free from the odor of Benzin, reduce it to powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, and moisten the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed very slowly, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until the Lactucarium is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims], and mix this with the reserved portion. Filter, and add enough Diluted Alcohol through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This is a new official tincture. It is based on the formula of J. L. Lemberger, who recommended the extraction of the resinous inert lactucerin by treatment with benzin. Great care must be observed in the selection of the benzin, as it is almost impossible to get rid of the odor and taste of petroleum in the finished preparation if the ordinary benzin be used. (See *Syrupus Lactucarii*, page 1337.)

TINCTURA LAVANDULÆ COMPOSITA. U. S., Br. Compound Tincture of Lavender. [Compound Spirit of Lavender.]

(TĬNC-TŪ′RĄ LĄ-VĂN′DŬ-LÆ CŌM-PŎŞ′Į-TĄ.)

Spiritus Lavandulæ Compositus, *U. S.* 1870; Compound Spirit of Lavender, Lavender Drops; Teinture de Lavande composée, *Fr.;* Zusammengesetzte Lavendeltinktur, *G.*

"Oil of Lavender Flowers, *eight cubic centimeters* [or 130 minims]; Oil of Rosemary, *two cubic centimeters* [or 32 minims]; Cassia Cinnamon, in coarse powder, *twenty grammes* [or 309

grains]; Cloves, *five grammes* [or 77 grains]; Nutmeg, *ten grammes* [or 154 grains]; Red Saunders, in coarse powder, *ten grammes* [or 154 grains]; Alcohol, *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims]; Water, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Oils in the Alcohol, and add the Water. Crush the Nutmeg in a mortar, mix it with the Cinnamon, Cloves, and Red Saunders, and reduce the mixture, by grinding, to a coarse (No. 20) powder. Moisten the mixture with a sufficient quantity of the alcoholic solution of the Oils, pack it firmly in a cylindrical percolator, gradually pour upon it the remainder of the alcoholic solution, and, afterwards, Diluted Alcohol, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Oil of Lavender, 45 *minims* or 4·7 cubic centimetres; Oil of Rosemary, 5 *minims* or 0·5 cubic centimetre; Cinnamon Bark, bruised, 75 *grains* or 8·5 grammes; Nutmeg, bruised, 75 *grains* or 8·5 grammes; Red Sanders Wood, 150 *grains* or 17 grammes; Alcohol (90 per cent.), 1 *pint* (Imperial measure) or 1000 cubic centimetres. Prepare by the maceration process, adding the Oils at the completion of the process." *Br.*

The compound spirit of lavender of the U. S. Pharmacopœia is nearly twice the strength of the British preparation, although it is made with a menstruum weaker in alcohol. When properly prepared it is an excellent preparation to be used for *gastric uneasiness*, *nausea*, and *flatulence*. The dose is from thirty drops to a fluidrachm (1·9–3·75 C.c.).

TINCTURA LIMONIS. Br. Tincture of Lemon.

(TĬNC-TŪ'RĄ LĮ-MŌ'NĬS.)

Teinture de Zeste de Limon, *Fr.;* **Citronenschalentinktur**, *G.*

"Fresh Lemon Peel, cut small, 5 *ounces* (Imperial) or 250 grammes; Alcohol (90 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture was doubled in strength at the 1898 revision of the Br. Pharm. It is now made with strong alcohol instead of proof spirit formerly used. It forms a grateful aromatic addition to tonic infusions, etc. Dose, from one to two fluidrachms (3·75–7·5 C.c.).

TINCTURA LOBELIÆ. U. S. Tincture of Lobelia.

(TĬNC-TŪ'RĄ LǪ-BĒ'LĮ-Æ.)

Teinture de Lobélie, *Fr.;* **Lobeliatinktur**, *G.*

"Lobelia, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

The strength of this tincture was increased one-third at the last revision. For method of assay, see *Chem. and Drug.*, 1893, 454; also *P. J. Tr.*, 1895, 141. It possesses the emetic and narcotic properties of lobelia, and is much used in *asthma*, in the dose of from one-half to one fluidrachm (1·9–3·75 C.c.), repeated every two or three hours till its effects are experienced. The emetic dose is two fluidrachms (7·5 C.c.), but it frequently acts dangerously. A saturated tincture is strongly recommended by Dr. A. Livezey as a local application in *erysipelas*, and in the *eczematous eruption of Rhus poisoning*. (*Bost. Med. and Surg. Journ.*, lv. 262.)

TINCTURA LOBELIÆ ÆTHEREA. Br. Ethereal Tincture of Lobelia.

(TĬNC-TŪ'RĄ LǪ-BĒ'LĮ-Æ Æ-THĒ'RĘ-Ą.)

"Lobelia, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Spirit of Ether, *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of Spirit of Ether, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with rather more than one and a half times the proportion of Lobelia ordered for the corresponding preparation in the British Pharmacopœia of 1885." *Br.*

Dose, from five to fifteen minims (0·3–0·9 C.c.).

TINCTURA MATICO. U. S. Tincture of Matico.

(TĬNC-TŪ'RĄ MĂT'Į-CŌ.)

"Matico, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the Matico with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

The tincture of matico is not so generally useful as the fluid extract, but is preferable in some cases when used in combination with other liquids. The dose is a fluidrachm (3·75 C.c.).

TINCTURA MOSCHI. U. S. Tincture of Musk.

(TĬNC-TŪ'RĄ MŌS'ĢHĪ.)

"Musk, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]; Water, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Musk in a mortar, first, with a little of the Water, until a smooth mixture is made, and then with the remainder of the Water. Transfer the whole to a bottle, add the Alcohol, and macerate the mixture for seven days, occasionally shaking the bottle. Then filter through paper, adding, through the filter, enough Diluted Alcohol to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This tincture has been reduced in strength about one-half, on account of the greatly increased cost of musk. This change, in our opinion, is ill-advised, and does not secure the main object, as the patient will now have to take double the dose, even if the alcohol be therapeutically contra-indicated. The process should be worded so as to make the end-product 100 C.c., as very few pharmacists will require 1000 C.c. of tincture of musk. Musk will yield its virtues to the above menstruum if the process be followed; if wanted for its odor it will be economy to add a minim of solution of potassa to the water used to rub the musk into a smooth paste. Care should be especially taken to use pure grain musk in this preparation. Dose, from thirty minims to two fluidrachms (1·9–7·5 C.c.).

TINCTURA MYRRHÆ. U. S., Br. Tincture of Myrrh.

(TĬNC-TŪ'RĄ MĬR'RHÆ.)

Teinture de Myrrhe, *Fr.*; Myrrhentinktur, *G.*

"Myrrh, in moderately coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the powder with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, and macerate for seven days in a closed vessel; then filter through paper, adding, through the filter, enough Alcohol to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Myrrh, in coarse powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Place the Myrrh with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol in a closed vessel; set aside for seven days, with frequent agitation; filter; when the liquid ceases to drop, pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The strength of this tincture was increased 60 per cent. at the last revision of the British Pharmacopœia (1898).

Official alcohol is preferable to diluted alcohol as a solvent of myrrh, because it forms a perfectly clear tincture, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. According to E. B. Shuttleworth (*A. J. P.*, xliii. 369), the gum which is left behind in making the tincture may be utilized for making mucilage. The tincture of myrrh is used solely as a local application to stimulate *indolent and foul ulcers*, *spongy gums*, *aphthous sore mouth*, and *ulcerations of the throat*. From fifteen to thirty minims (0·9–1·9 C.c.) has been set down as the dose.

TINCTURA NUCIS VOMICÆ. U. S., Br. Tincture of Nux Vomica.

(TĬNC-TŪ'RĄ NŪ'CĮS VŎM'Į-ÇÆ.)

Tinctura Strychni, *P. G.;* Teinture de Noix-vomique, *Fr.;* Krähenaugentinktur, *G.*

"Extract of Nux Vomica, dried at 100° C. (212° F.), *twenty grammes* [or 309 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Extract of Nux Vomica (which should contain *fifteen per cent.* of alkaloids) in a sufficient quantity of a mixture of *three volumes* of Alcohol and *one volume* of Water, to make the Tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Liquid Extract of Nux Nomica, 2 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Distilled Water, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Liquid Extract of Nux Vomica with the Distilled Water; add sufficient of the Alcohol to produce *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Tincture; filter. Treated by the assay process given under 'Extractum Nucis Vomicæ Liquidum,' 100 cubic centimetres should yield not less than 0·24 nor more than 0·26 gramme of Strychnine, corresponding to about ¼ grain in 1 fluid drachm or ¼ grain in 110 minims. This preparation contains about twice the proportion of Strychnine present in the Tincture of Nux Vomica of the British Pharmacopœia of 1885." *Br.*

The object of the U. S. 1890 process is to secure a more reliable and definite tincture than was possible under the old process; for this reason 2 per cent. of the standardized extract is directed to be dissolved in a mixture of 3 volumes of alcohol and 1 volume of water. On account of the very tough structure of nux vomica, percolation is accomplished usually with varying results. The amount of extract present in the percolate is to some extent a measure of its activity: hence, if a weighed portion of the percolate is evaporated to dryness, and the percentage of dry extract is noted, it is easy to calculate the amount present in the whole quantity. The official test directs that "if 100 C.c. of Tincture of Nux Vomica be evaporated to dryness, and the residue tested by the process of assay given under *Extractum Nucis Vomicæ*, it should be found to contain 0·3 Gm. of alkaloids." *U. S.* The British Pharmacopœia standardizes the liquid extract (see p. 580), and makes its tincture from it of such strength that 100 C.c. shall contain 0·25 Gm. of strychnine; the menstruum used is slightly more alcoholic than that of the Br. Ph. 1885. Mr. R. Rother (*A. J. P.*, Jan. 1883), after experimenting with various substances, found that sodium chloride aided greatly in softening the bassorin-like substance in which the alkaloidal principles of nux vomica are embedded, and he proposes its use by adding it to the menstruum of diluted alcohol in the proportion of 120 grains to the pint. (See *U. S. D.*, 16th ed., p. 1527.) The alcoholic extract, or strychnine, is preferable to the tincture, when the pill form is practicable. Mr. Geo. W. Kennedy has noticed the crystallization of strychnine in the tincture, seemingly due to the formation of ammonia in it. (*A. J. P.*, xlii. 299, 392.) The dose of the tincture is twenty minims (1·25 C.c.), to be increased if necessary.

TINCTURA OPII. U. S., Br. Tincture of Opium. [Laudanum.]

(TĬNC-TŪ'RĄ Ō'PĮ-Ī.)

Tinctura Opii Simplex, *P. G.;* Tinctura Thebaica, Tinctura Meconii; Teinture d'Opium, Teinture thébaïque, *Fr.;* Einfache Opiumtinktur, *G.*

"Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Precipitated Calcium Phosphate, *fifty grammes* [or 1 ounce av., 334 grains]; Water, *four hundred cubic centimeters* [or 13 fluidounces, 252 minims]; Alcohol, *four hundred cubic centimeters* [or 13 fluidounces, 252 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the powders in a mortar, with the Water previously heated to the temperature of 90° C. (194° F.), until a smooth mixture is made, and macerate for twelve hours; then add the Alcohol, mix thoroughly, and transfer the whole to a cylindrical percolator. Return to the percolator the first portion of the percolate, until it runs through clear, and, when the liquid ceases to drop, gradually pour on Diluted Alcohol, continuing the percolation slowly, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of the Tincture are obtained." *U. S.* (See assay, p. 1398.)

"Opium, 3 *ounces* (Imperial) or 150 grammes; Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity*. Rub the Opium to a paste with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water, previously heated to at least 200° F. (93·3° C.); set aside for six hours; add *ten fluid ounces* (Imp. meas.) or five hundred cubic centi-

metres of the Alcohol; mix thoroughly; set aside in a covered vessel for twenty-four hours; strain; press; mix the liquids; set aside for twenty-four hours; filter.

"Determine the proportion of morphine in the resulting strong tincture by the following process: Pour 80 cubic centimetres of the liquid into a porcelain dish; evaporate on a water-bath until the volume is reduced to 30 cubic centimetres; mix the residual liquid in a mortar with 3 grammes of freshly slaked *lime;* dilute the mixture with *water* to 85 cubic centimetres; set aside for half an hour, stirring occasionally. Filter off 50 cubic centimetres of the liquid (representing 50 cubic centimetres of the strong tincture) through a plaited filter, having a diameter of about one decimetre, into a wide-mouthed stoppered bottle, having a capacity of two hundred cubic centimetres; add 5 cubic centimetres of *alcohol* (90 per cent.) and 30 cubic centimetres of *ether;* shake the mixture; add 2 grammes of *ammonium chloride;* shake well and frequently during half an hour; set aside for 12 hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the bottle as completely as possible by means of a small pipette, and transfer it to the filter; pour into the bottle 15 cubic centimetres of *ether;* rotate the contents and set the bottle aside; transfer the separated ethereal layer carefully, by means of the pipette, to the filter; wash the filter with a total amount of 10 cubic centimetres of *ether* added slowly, and in portions; let the filter dry in the air; pour upon it the liquid in the bottle, in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the bottle with *morphinated water*, until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain; dry it, first by gentle pressure between sheets of bibulous paper, afterwards at a temperature between 131° and 140° F. (55° and 60° C.), finally at 230° F. (110° C.) for 2 hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0·3 gramme of the crystals, and titrate with *decinormal volumetric solution of sulphuric acid*, as directed under Opium.

"Add to the weight of anhydrous morphine, indicated by the titration, 0.05 gramme (or 0·1 gramme for every 100 cubic centimetres of the original filtrate, should more than 50 cubic centimetres have been used for the estimation), a proportion representing the average loss of morphine during the process.

"Having ascertained the proportion of morphine, calculated as anhydrous, present in the 50 cubic centimetres of strong tincture, the remainder is to be diluted with sufficient of a mixture of Alcohol (90 per cent.) and Distilled Water, in equal volumes, to produce a Tincture of Opium containing 0·75 gramme of morphine, calculated as anhydrous, in 100 cubic centimetres. Treated by the foregoing process, Tincture of Opium should yield an amount of morphine, reckoned as anhydrous, corresponding to not less than 0·70 gramme, nor more than 0·80 gramme, in 100 cubic centimetres. This preparation contains, on an average, the soluble matter of 32·8 grains of Opium (containing 10 per cent. of morphine, calculated as anhydrous) in 1 fluid ounce, or about 1 grain of such opium in 15 minims. Tincture of Opium may be prepared with any variety of opium containing a known percentage of morphine, calculated as anhydrous, provided that the percentage be not less than seven and a half, and provided that the resulting Tincture of Opium respond to the foregoing quantitative test." *Br.*

The proportion of opium in these formulas is not the same, the U. S. P. tincture containing about twelve grains more of opium in the fluidounce than the British. The Br. Ph. 1898 does not direct opium *in powder*, but relies upon an assay to bring the product to a uniform strength. The drying and powdering of the opium are clearly useful provisions, as they insure greater uniformity in the strength of the tincture. Crude opium contains variable proportions of water; and laudanum prepared from a moist specimen will be weaker than that prepared from an equal weight of the dried. The pulverization insures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum: it is, however, often neglected. Deviation from the official strength in so important a preparation is certainly a great evil. There can be little doubt, we think, that the present U. S. formula insures a more complete exhaustion of the opium than did the former simple procedure of maceration for six days, whilst the saving in time is apparent. *Pure* precipitated calcium phosphate has been added, and *finely* powdered opium directed in the U. S. 1890 process, because much trouble seems to have been experienced in procuring at all times in the market the *coarsely* powdered opium which was the only kind suitable for use in the U. S.

1880 process. Opium in fine powder cannot be readily percolated with diluted alcohol, but if it be mixed with half its weight of an insoluble powder like pure calcium phosphate there will be no difficulty: percolation will necessarily be slow, but this is just what is required to secure thorough exhaustion.*

In the United States and Great Britain this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so applied on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by very nearly 10·5 minims, according to the U. S. formula of 1890; but a minute quantity of morphine has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate. This difference, however, is too slight to be of any practical importance. In general practice, laudanum very rarely fully comes up to the official standard, and a large proportion of that in the market is far below it. This is especially the case with the cheap laudanums which are so extensively sold to country stores.

The official requirements are that "if 100 C.c. of Tincture of Opium be assayed by the process immediately following, it should yield from 1·3 to 1·5 Gm. of crystallized morphine.

"Assay of Tincture of Opium.

"Tincture of Opium, *one hundred cubic centimeters;* Ammonia Water, *three and five-tenths cubic centimeters;* Alcohol, Ether, Water, each, *a sufficient quantity*. Evaporate the Tincture to about 20 C.c., add 40 C.c. of water, mix thoroughly, and set the liquid aside for an hour, occasionally stirring, and disintegrating the resinous flakes adhering to the capsule. Then filter, and wash the filter and residue with water, until all soluble matters are extracted, collecting the washings separately. Evaporate in a tared capsule, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 14 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 C.c., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 20 Gm. Then add 10 Gm. (or 12·2 C.c.) of alcohol, shake well, add 25 C.c. of ether, and shake again. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night. Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly-acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 C.c. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 C.c. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 C.c. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-water, and afterwards wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 C.c., or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them. The weight found represents the amount of crystallized morphine obtained from 100 C.c. of the Tincture." *U. S.*
(See *Opium*, page 997.)

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium*.) The dose, equivalent to a grain of opium, is about eleven minims (0·65 C.c.), or

* *Tinctura Opii Muriatica.* Under this name is sometimes prescribed a preparation made by the following formula. Powdered Opium *one ounce;* Muriatic Acid *one fluidounce;* Distilled Water *fifteen fluidounces.* Macerate for 14 days, filter, and add sufficient water to make a pint.

twenty-two drops. It should be recollected that a fluidrachm or teaspoonful of laudanum (60 minims) will yield, on an average, about 120 drops. Laudanum, when long kept, with occasional exposure to the air, becomes thick from the evaporation of a portion of the alcohol and the deposition of opium. If given in this state, it often acts with unexpected energy; and death has resulted in infants from doses which would have been entirely safe if the tincture had been clear. *Denarcotized laudanum* may be prepared by substituting the denarcotized opium for the opium itself.

TINCTURA OPII AMMONIATA. Br. Ammoniated Tincture of Opium.

(TĬNC-TŪ'RĄ Ō'PĮ-Ī ĄM-MŌ-NĮ-Ā'TĄ.)

Scotch Paregoric; Teinture d'Opium ammoniacale, *Fr.;* Ammoniakalischeopiumtinktur, *G.*

"Tincture of Opium, 3 *fl. ounces* (Imperial measure) or 150 cubic centimetres; Benzoic Acid, 180 *grains* or 20·6 grammes; Oil of Anise, 1 *fl. drachm* (Imp. meas.) or 625 cubic centimetres; Solution of Ammonia, 4 *fl. ounces* (Imp. meas.) or 200 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity.* Dissolve the Oil of Anise and the Benzoic Acid in *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Alcohol; add the Tincture of Opium and the Solution of Ammonia; mix well; filter; add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This preparation contains the soluble matter of nearly 0·62 grain of Opium (containing 10 per cent. of morphine, reckoned as anhydrous) in 1 fluid drachm, or of nearly 5 grains of such Opium in 1 fluid ounce." *Br.*

This is an old preparation of the Edinburgh Pharmacopœia, formerly used in Scotland under the name of Paregoric Elixir. It differs, however, both in composition and in strength, from the very popular preparation known as Paregoric in the United States. As ammonia precipitates morphine from its solutions, it was doubted whether the tincture contained any of that alkaloid; but if the ammonia be in sufficient excess it will redissolve the morphine. At best, however, the preparation is of doubtful propriety; for if the ammoniacal addition should not happen to have the requisite strength, or if the ammonia should escape or become carbonated by exposure, the strength of the tincture might be affected. Influenced, we presume, by considerations of this kind, the editors of the first British Pharmacopœia rejected the preparation altogether. But popular preference, although local, led to its readmission into the Br. Pharmacopœia, though in a slightly modified form, strong solution of ammonia and rectified spirit being substituted for the Edinburgh spirit of ammonia, which is not official in the Br. Pharmacopœia. The dose is stated at from thirty minims to a fluidrachm (1·9–3·75 C.c.).

TINCTURA OPII CAMPHORATA. U. S. (Br.) Camphorated Tincture of Opium. [Paregoric.]

(TĬNC-TŪ'RĄ Ō'PĮ-Ī CĂM-PHQ-RĀ'TĄ.)

Tinctura Camphoræ Composita, *Br.;* Compound Tincture of Camphor, Paregoric Elixir; Tinctura Opii Benzoica, *P. G.;* Elixir Paregoricum; Elixir parégorique, *Fr.;* Benzoësaurehaltige Opiumtinktur, *G.*

"Powdered Opium, *four grammes* [or 62 grains]; Benzoic Acid, *four grammes* [or 62 grains]; Camphor, *four grammes* [or 62 grains]; Oil of Anise, *four cubic centimeters* [or 65 minims]; Glycerin, *forty cubic centimeters* [or 1 fluidounce, 169 minims]; Diluted Alcohol, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Add *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol to the other ingredients, contained in a suitable vessel, and macerate for three days, shaking frequently; then filter through paper, in a well-covered funnel, and pass enough Diluted Alcohol through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Tincture of Opium, 585 *minims* or 60·9 cubic centimetres; Benzoic Acid, 40 *grains* or 4·6 grammes; Camphor, 30 *grains* or 3·4 grammes; Oil of Anise, 30 *minims* or 3·1 cubic centimetres; Alcohol (60 per cent.), *a sufficient quantity.* Dissolve the Benzoic Acid, Camphor, and Oil of Anise in *eighteen fluid ounces* (Imperial measure) or nine hundred cubic centimetres of the Alcohol; add the Tincture of Opium and a sufficient quantity of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture; filter if necessary. This Compound Tincture of Camphor contains in each fluid drachm a proportion of Tincture of Opium equivalent to $\frac{1}{30}$ grain of Morphine Hydrochloride, or to $\frac{1}{4}$ grain of Opium (containing 10 per cent. of anhydrous morphine); or to nearly 0·5 milligramme (0.00046 gramme) of anhydrous morphine in each cubic centimetre." *Br.*

This is the well-known *paregoric*. It is a very pleasant anodyne, much used to allay *cough*, to relieve *nausea* and slight *pains in the stomach and bowels*, to check *diarrhœa*, and, in infantile cases, to *procure sleep*. Half a fluidounce of the U. S. or British tincture contains rather less than a grain of powdered opium. The substitution of glycerin for the honey of the U. S. P. 1870 is an improvement which aids in retaining the transparency of the filtered tincture. Liquorice was omitted in 1840, in consequence of giving the dark color of laudanum and thus leading to mistake. The dose for an infant is from five to twenty drops (0·3–1·25 C.c.), for an adult from one to four fluidrachms (3·75–15 C.c.).*

TINCTURA OPII DEODORATI. U. S. Tincture of Deodorized Opium.

[Tinctura Opii Deodorata, Pharm. 1880.]

(TĬNC-TŪ'RĄ Ō'PĮ-Ī DĘ-Ō-DǪ-RĀ'TĪ.)

"Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Precipitated Calcium Phosphate, *fifty grammes* [or 1 ounce av., 334 grains]; Ether, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Alcohol, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the powders in a mortar with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water previously heated to the temperature of 90° C. (194° F.), until a smooth mixture is made, and macerate for twelve hours; then pour the mixture on a filter, or transfer it to a cylindrical percolator, and gradually pour on Water, until the Opium is practically exhausted. Reduce the percolate, by evaporation on a water-bath, to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], and, when it has cooled, shake it repeatedly with the Ether in a bottle. When the ethereal solution has separated by standing, pour it off, and evaporate the remaining liquid until all traces of Ether have disappeared. Mix the residue with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, and filter the mixture through paper. When the liquid has ceased to pass, add enough Water, through the filter, to make the filtered liquid measure *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]. Lastly, add the Alcohol and mix them. If 100 C.c. of Tincture of Deodorized Opium be assayed by the process given under *Tinctura Opii*, it should yield from 1·3 to 1·5 Gm. of crystallized morphine." *U. S.*

This is an excellent preparation of opium, calculated to supersede various extra-official *elixirs* or *solutions*, which have had more or less use, based upon the real advantages they afforded, in offering liquid preparations of opium exempt from certain noxious ingredients in the crude drug and in the official tinctures which rendered them so offensive to some constitutions, and in some conditions of disease, as almost to forbid their use. A liquid extract is first made, in which are left behind all the ingredients of opium insoluble in water; and this, being well shaken with ether, is further deprived of all the principles soluble in this fluid, including narcotine and the noxious odorous matter which is probably one of the most offensive and least useful constituents of opium. The ether is then entirely separated, and, the residue having been dissolved in water, the solution is filtered, and mixed with enough alcohol to preserve it. It has been repeatedly recommended by several pharmacists to replace the ether with benzin, which removes the narcotine just as well as does ether, and has the merit of being much cheaper. The objection, however, is that benzin almost invariably leaves a trace of a taste and an odor like those of petroleum, and hence it is not fitted for use in a remedy used almost exclusively internally. Prof. Patch found that acetone, which had been suggested as a substitute for ether.

* The following formulas were adopted by the Philadelphia College of Pharmacy in 1833 for the preparation of the old compound tinctures of opium so much used under the names of *Bateman's drops* and *Godfrey's cordial*. So long as these nostrums are employed, it is important that they should be prepared in a uniform manner and of a certain strength, as serious consequences may happen from diversity in the formulas when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent; so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil that the College was induced to adopt the formulas here presented.

"*Bateman's Pectoral Drops.* Take of Diluted Alcohol Cong. iv, Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium, in powder, ℥ij, Catechu, in powder, ℥ij, Camphor ℥ij, Oil of Anise f ℥iv. Digest for ten days." This preparation is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U. S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's Cordial.* Take of Tincture of Opium Oiss, Molasses (from the sugar refiners) Oxvj, Alcohol Oij, Water Oxxvj, Potassium Carbonate ℥iiss, Oil of Sassafras f ℥iv. Dissolve the Potassium Carbonate in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum, Alcohol, and Oil of Sassafras, having previously mixed them well together. This preparation contains the strength of rather more than one grain of opium in a fluidounce." (*Journ. of the Phila. Coll. of Pharm.*, v. 26 and 27.) Death has been produced by it in the infant. (*P. J. Tr.*, 3d ser., i. 199.)

was open to the same objection as benzin. The following simplified process was proposed by E. C. Federer as a substitute for the official one. Macerate the dried and powdered drug in twice its weight of water at about 138° F. (a mixture of 1 part of water at about from 50° to 75° F. with 1 part at about 210° F.) overnight, or about 12 hours, in a moderately warm place not above from 80° to 90° F., in a partially closed flask. Pour the mass into a wetted double precipitate filter: when the liquid ceases to pass, rinse out the flask with 1 part more of the water at about 138° F., and pass this through the mass. Repeat this once, and, if necessary, again repeat, so as to obtain from 4 to 5 parts of moderately concentrated liquor; the residue will under these circumstances become exhausted. Cool the percolate to as near 32° F. as possible, and filter, placing a piece of ice in the filter to keep the temperature down. If necessary, repass the first portion until the liquid comes through clear; when the last portion has passed, wash the filter with sufficient ice-water to obtain a filtrate of 8 parts; lastly, add alcohol 2 parts. Mr. Federer states that a permanent, bright, clear tincture results, practically free from narcotine and thoroughly deodorized. (*Drug. Circ.*, 1887, 77.) Dose, from ten to thirty minims (0·6–1·8 C.c.).

TINCTURA PHYSOSTIGMATIS. U. S. Tincture of Physostigma.

(TĬNC-TŪ'RĄ PHĬ-SO-STĬG'MĄ-TĬS.)

"Physostigma, in No. 40 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This *tincture of Calabar Bean* is much weaker than that proposed by Dr. Fraser, which was nearly as strong as a fluid extract,—five minims representing three grains of the drug. (See page 1028.) The dose of the official tincture is from twenty to forty minims (1·25–2·5 C.c.).

TINCTURA PODOPHYLLI. Br. Tincture of Podophyllum.

(TĬNC-TŪ'RĄ PŎD-O-PHĬL'LĪ.)

"Podophyllum Resin, 320 *grains* or 36·5 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Add the Podophyllum Resin to *eighteen fluid ounces* (Imperial measure) or nine hundred cubic centimetres of the Alcohol, and set aside for twenty-four hours, occasionally agitating; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This Tincture contains twice the proportion of Podophyllum Resin ordered for the corresponding preparation in the British Pharmacopœia of 1885." *Br.*

The introduction of this tincture is of doubtful utility. It may be given in doses of from five to fifteen minims (0·3–0·9 C.c.).

TINCTURA PRUNI VIRGINIANÆ. Br. Tincture of Virginian Prune.

(TĬNC-TŪ'RĄ PRŪ'NĪ VĬR-ĢĬN-Ī-Ā'NÆ.)

"Virginian Prune Bark, in No. 20 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (90 per cent.), 12½ *fl. ounces* (Imp. meas.) or 625 cubic centimetres; Distilled Water, 7½ *fl. ounces* (Imp. meas.) or 375 cubic centimetres. Mix the powder with the Distilled Water; set aside in a closed vessel for twenty-four hours; add the Alcohol, and complete the maceration process." *Br.*

This is a new official tincture of the Br. Ph. 1898; its utility is doubtful, and its new English name is more than unfortunate. The use of a little glycerin to retard precipitation would be advisable. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

TINCTURA PYRETHRI. U. S., Br. Tincture of Pyrethrum.

(TĬNC-TŪ'RĄ PĪ-RĒ'THRĪ.)

Tincture of Pellitory; Teinture de Pyrèthre, *Fr.*; Bertramwurzeltinktur, *G.*

"Pyrethrum, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical perco-

lator, and gradually pour alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Pyrethrum Root, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *three fluid ounces* (Imp. meas.) or one hundred and fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture is a powerful local irritant, and is an ingredient in several well-known mouth- and tooth-washes. For its uses, which are purely external, see *Pyrethrum*.

TINCTURA QUASSIÆ. U. S., Br. Tincture of Quassia.

(TĬNC-TŪ'RĄ QUAS'SI-Æ.)

Teinture de Quassie, *Fr.;* Quassiatinktur, *G.*

"Quassia, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 gr.]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Alcohol to *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Water. Having moistened the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Quassia Wood, rasped, 2 *ounces* (Imperial) or 100 grammes; Alcohol (45 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture was omitted in the first British Pharmacopœia, but has been resumed in the present; the proportion of quassia was increased nearly threefold at the 1898 revision, and the preparation is now identical in strength with the U. S. P. tincture. The tincture may be employed as an addition to tonic infusions or mixtures in the dose of one fluidrachm (3·75 C.c.).

TINCTURA QUILLAJÆ. U. S. (Br.) Tincture of Quillaja.

(TĬNC-TŪ'RĄ QUĬL-LĀ'JÆ—kwĭl-lā'yē.)

"Quillaja, coarsely ground, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Boil the Quillaja, placed in a suitable vessel, with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water for fifteen minutes, strain, and wash the residue on the strainer with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water. Then boil the strained liquid down to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims], allow it to cool, mix it with the Alcohol, and, when the insoluble matter has subsided, filter the liquid portion through paper, and add enough Water to make the tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Quillaia Bark, in No. 20 powder, 1 *ounce* (Imperial) or 50 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *half a fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture, official in the U. S. P. 1890 for the first time, is almost exclusively used as an emulsifying agent. Its medical activity, however, limits its use. (See *Quillaja*, p. 1133.) The British tincture is only one-fourth the strength of the U. S. preparation, its dose being from one-half to one fluidrachm (1·9–3·75 C.c.).

TINCTURA QUININÆ. Br. Tincture of Quinine.

(TĬNC-TŪ'RĄ QUĪ-NĪ'NÆ.)

"Quinine Hydrochloride, 175 *grains* or 20 grammes; Tincture of Orange, 1 *pint* (Imperial measure) or 1000 cubic centimetres. Dissolve the Quinine Hydrochloride in the Tincture of Orange." *Br.*

Quinine sulphate was replaced in this preparation by the hydrochlorate in the 1885 Br. Pharmacopœia, because, as pointed out by Mr. Wright (*Year-Book of Pharm.*, 1884, 537), the sulphate was not always soluble in the proportion of tincture of orange peel ordered. Tonic dose, a fluidrachm (3·75 C.c.) (about equal to $1\frac{1}{10}$ grains of quinine hydrochloride).

TINCTURA QUININÆ AMMONIATA. Br. Ammoniated Tincture of Quinine.

(TĬNC-TŪ'RĄ QUĪ-NĪ'NÆ ĂM-MŌ-NĮ-Ā'TĄ.)

"Quinine Sulphate, 175 *grains* or 20 grammes; Solution of Ammonia, 2 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Alcohol (60 per cent.), 18 *fl. ounces* (Imp. meas.) or 900 cubic centimetres. Mix the Solution of Ammonia with the Alcohol; add the Quinine Sulphate; shake until a clear solution is produced; set aside for three days; filter." *Br.*

A fluidrachm (3·75 C.c.) represents about $1\frac{1}{10}$ grains of quinine sulphate, and is the dose.

TINCTURA RHEI. U. S. (Br.) Tincture of Rhubarb.

(TĬNC-TŪ'RĄ RHĒ'Ī.)

Tinctura Rhei Composita, *Br.,* Compound Tincture of Rhubarb; Teinture de Rhubarbe, *Fr.;* Rhabarbertinktur, *G.*

"Rhubarb, *one hundred grammes* [or 3 ounces av., 231 grains]; Cardamom, *twenty grammes* [or 309 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Rhubarb and Cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum. and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of Alcohol and Water, made in the same proportions as before, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Rhubarb Root, in No. 20 powder, 2 *ounces* (Imperial) or 100 grammes; Cardamom Seeds, bruised, ¼ *ounce* (Imp.) or 12·5 grammes; Coriander Fruit, bruised, ¼ *ounce* (Imp.) or 12·5 grammes; Glycerin, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), *a sufficient quantity.* Moisten the solid ingredients with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol; proceed with the percolation process until a volume of *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of liquid has been obtained; agitate; set aside for forty-eight hours; filter; mix with the Glycerin." *Br.*

The tincture of rhubarb on standing lets fall a yellow deposit. This has been shown by Mr. James T. King (*A. J. P.,* xlii.) to be in most cases largely composed of chrysophanic acid. He proposed to remedy this by the use of a stronger alcohol, or, as recommended by Mr. J. B. Moore (*A. J. P.,* xlv. 306), by the substitution of glycerin for a portion of the alcohol. We have not found that either of these plans entirely prevents precipitation; although glycerin is an aid in this direction. Dose, from one to two fluidrachms (3·75–7·5 C.c.).

TINCTURA RHEI AROMATICA. U. S. Aromatic Tincture of Rhubarb.

(TĬNC-TŪ'RĄ RHĒ'Ī ĂR-Ǫ-MĂT'Ī-CĄ.)

"Rhubarb, *two hundred grammes* [or 7 ounces av., 24 grains]; Cassia Cinnamon, *forty grammes* [or 1 ounce av., 180 grains]; Cloves, *forty grammes* [or 1 ounce av., 180 grains]; Nutmeg, *twenty grammes* [or 309 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, Diluted Alcohol, each, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Rhubarb, Cinnamon, Cloves, and Nutmeg, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the Glycerin with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol and *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This is the tincture which is used in making the aromatic syrup of rhubarb. It is prefer-

able to separate the preparations, as it is occasionally desirable to prescribe the tincture without the admixture with syrup, whilst the pharmacist will always prefer to make the tincture in quantity and keep it on hand, since it is permanent, and add it to syrup to make the aromatic syrup when needed. Dose, for an adult, from one-half to one fluidrachm (1·9–3·75 C.c.).

TINCTURA RHEI DULCIS. U. S. Sweet Tincture of Rhubarb.

(TĬNC-TŪ'RĄ RHĒ'Ī DŬL'CIS.)

"Rhubarb, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycyrrhiza, *forty grammes* [or 1 ounce av., 180 grains]; Anise, *forty grammes* [or 1 ounce av., 180 grains]; Cardamom, *ten grammes* [or 154 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, Diluted Alcohol, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Rhubarb, Glycyrrhiza, Anise, and Cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the Glycerin with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol and *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This is a tincture which has been frequently used in Philadelphia and other sections of our country: it is preferable to the simple tincture for administration to children, on account of its more agreeable taste. The dose is from two to three fluidrachms (7·5–11·25 C.c.).

TINCTURA SANGUINARIÆ. U. S. Tincture of Sanguinaria. [Tincture of Bloodroot.]

(TĬNC-TŪ'RĄ SĂN-GUĮ-NĀ-RĮ-Æ.)

Teinture de Sanguinaire, *Fr.;* Blutwurzeltinktur, *G.*

"Sanguinaria, in No. 60 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Acetic Acid, *twenty cubic centimeters* [or 325 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the mixture to which the Acetic Acid had previously been added, and macerate for twenty-four hours; then pack it firmly in a cylindrical glass percolator, gradually pour on more of a mixture of Alcohol and Water, made in the same proportions as before, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

A precipitate will generally be found deposited upon the sides and bottoms of bottles containing this tincture. W. J. McConn (*A. J. P.*, 1884, p. 505) recommends the addition of an alkaline citrate, preferably potassium citrate, as a preventive. He found sanguinarine in the precipitate. The official menstruum now contains 20 per cent. of acetic acid, with a view of preventing precipitation. This tincture is emetic in the dose of from three to four fluidrachms (11·25–15 C.c.); but it is rather intended to act as an expectorant or an alterative, for which purpose from thirty to sixty drops (1·9–3·75 C.c.) may be given.

TINCTURA SCILLÆ. U. S., Br. Tincture of Squill.

(TĬNC-TŪ'RĄ SQĬL'LÆ.)

Teinture de Scille, *Fr.;* Meerzwiebeltinktur, *G.*

"Squill, in No. 30 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the menstruum, and macerate for twenty-four hours; then pack it moderately in a conical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Squill, bruised, 4 *ounces* (Imperial) or 200 grammes; Alcohol (60 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture yields a grayish, rose-colored, very bitter and acrid deposit, consisting of silky tufts. (Ménière.) It possesses all the virtues of squill, and may be given whenever the spirituous menstruum is not objectionable. The dose as an expectorant or a diuretic is from ten to twenty minims (0·6–1·25 C.c.) (from twenty to forty drops).

TINCTURA SENEGÆ. Br. Tincture of Senega.

(TĬNC-TŪ'RĄ SĔN'Ę-ÇÆ.)

Teinture de Polygale de Virginie, *Fr.;* **Senegatinktur,** *G.*

"Senega Root, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (60 per cent.), *a sufficient quantity.* Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent. The tincture is efficient, but it is hardly needed while recourse can be had to the fluid extract or the syrup. The dose is from thirty minims to two fluidrachms (1·9–7·5 C.c.).

TINCTURA SENNÆ COMPOSITA. Br. Compound Tincture of Senna.

(TĬNC-TŪ'RĄ SĔN'NÆ CŌM-PŌŞ'Ī-TĄ.)

Elixir Salutis; Teinture de Séné aromatique, Elixir de Salut, *Fr.;* **Sennatinktur,** *G.*

"Senna, broken small, 4 *ounces* (Imperial) or 200 grammes; Raisins of commerce, freed from seeds, 2 *ounces* (Imp.) or 100 grammes; Caraway Fruit, bruised, ½ *ounce* (Imp.) or 25 grammes; Coriander Fruit, bruised, ½ *ounce* (Imp.) or 25 grammes; Alcohol (45 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

The Br. Pharm. 1898 increased the proportion of senna in this preparation 60 per cent.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in *costiveness* attended with flatulence, and in *atonic gout*, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. The dose is from two fluidrachms to half a fluidounce (7·5–15 C.c.) or more. Tincture of senna gives a yellow deposit, disposed in plates, containing starch and white crystals of calcareous salts. (Ménière.)

TINCTURA SERPENTARIÆ. U. S., Br. Tincture of Serpentaria.

(TĬNC-TŪ'RĄ SĔR-PĘN-TĀ'RĮ-Æ.)

Tincture of Serpentary; Teinture de Serpentaire, *Fr.;* **Schlangenwurzeltinktur,** *G.*

"Serpentaria, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of tincture are obtained." *U. S.*

"Serpentary Rhizome, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture is little other than a feebly aromatic, alcoholic stimulant. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., and it is now double the strength of the U. S. P. tincture. Dose, from one to four fluidrachms (3·75–15 C.c.); of the British tincture, half these quantities.

TINCTURA STRAMONII SEMINIS. U. S. (Br.) Tincture of Stramonium Seed. [Tinctura Stramonii, Pharm. 1880.]

(TĬNC-TŪ'RĄ STRĄ-MŌ'NĮ-Ī SĔM'Į-NĬS.)

Tinctura Stramonii, *Br.;* **Teinture de Semences de Stramoine,** *Fr.;* **Stechapfelsamentinktur,** *G.*

"Stramonium Seed, in No. 40 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred cubic centimeters* [or 3 fluid-

ounces, 183 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Stramonium Leaves, in No. 20 powder, 4 *ounces* (Imperial) or 200 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., but changed the form of the drug from seed to leaves. This probably reduces the increase somewhat, as the seeds contain a larger percentage of alkaloids. This is an active preparation, the dose of which is from ten to twenty minims (0·6–1·25 C.c.).

TINCTURA STROPHANTHI. U. S., Br. Tincture of Strophanthus.

(TĬNC-TŪ'RĄ STRŌ-PHĂN'THĪ.)

"Strophanthus, in No. 30 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Digest the powder with *seventy cubic centimeters* [or 2 fluidounces, 176 minims] of the menstruum for two days, then transfer it to a cylindrical percolator, gradually pour menstruum upon it, and continue the percolation very slowly, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Strophanthus Seeds, in No. 30 powder, ½ *ounce* (Imperial) or 25 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Pack the powder in a percolator; moisten it with *one fluid drachm* (Imp. meas.) or six cubic centimetres of the Alcohol; set aside for forty-eight hours; pour on successive quantities of the Alcohol, allowing percolation to proceed slowly, until a total volume of *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of percolate has been obtained; filter; add a sufficient quantity of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This preparation is made with half the proportion of Strophanthus Seeds ordered for the corresponding preparation in the British Pharmacopœia of 1885 (Additions 1890)." *Br.*

The Br. Pharm. 1885 preparation was based on Prof. Fraser's formula, as improved by Wm. Martindale;* but the 1898 revision practically adopted the process of the U. S. tincture and dropped the method of previous treatment with ether to remove the fatty oil. Undoubtedly the simplest way of overcoming this difficulty is to add sufficient water to the alcoholic menstruum to prevent the solution of the oil, which is thus thrown out with the residue. Warrington subjects the tincture to a temperature of 32° F. and filters out the fatty deposit. (*West. Drug.*, 1892, 448.) Strophanthus seeds are reduced to powder with great difficulty. Dr. Squibb bruises them (after drying perfectly) in an iron mortar with broken glass. (*Ephemeris*, vol. iii. 1252.) Made by either process, the tincture is usually slightly cloudy when first prepared, but on standing soon becomes of a bright amber color. Benzin has been used in place of ether in Fraser's process for extracting the fixed oil, but it has only the advantage of economy, communicating a petroleum-like taste and odor to the tincture. The strength of the two tinctures is not the same, the U. S. tincture being double the strength of the British.

Medical Properties. This is an efficient and popular preparation, which fully represents the crude drug. (See *Strophanthus*.) Dose, from five to fifteen minims (0·3–0·9 C.c.).

* *Tincture of Strophanthus.* (Prof. Fraser's process.) Strophanthus Seeds, deprived of their comose appendices, reduced to powder, and dried, 1 ounce; Ether, freed from spirit and from water, 10 fluidounces; Rectified Spirit (alcohol), a sufficiency to obtain 1 pint, or 20 fluidounces. Remove entirely the stalks and comose appendices from the seeds, reduce the seeds to a moderately fine powder, dry the powder by exposing for twelve hours to a temperature of 100° or 120° F., and weigh. Pack in a percolator, add ether until the whole of the powder is saturated and a small quantity of the ether has dropped into the percolator; arrest the percolation for twenty-four hours, and then continue percolating slowly until the whole of the ether has been used. If the last ether percolate should not be almost colorless, use more ether. Remove the powder from the percolator, expose to the air, and break up any lumps after the ether has sufficiently evaporated; continue the exposure, heating the powder, if necessary, to 100° or 120° F., until all the ether has evaporated, when a uniform, nearly white, dry powder may be easily obtained. Repack the powder in the percolator, add enough of rectified spirit to moisten it thoroughly, arrest the further flow of the spirit, macerate for forty-eight hours, and pass rectified spirit slowly through until 20 fluidounces of tincture have been obtained.

TINCTURA SUMBUL. U. S., Br. Tincture of Sumbul.

(TĬNC-TŪ'RĄ SŬM'BŬL.)

Teinture de Sumbul, *Fr.;* Moschuswurzeltinktur, *G.*

"Sumbul, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Sumbul Root, bruised, 2 *ounces* (Imperial) or 100 grammes; Alcohol (70 per cent.), 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture is very little if at all employed in this country: for its medical properties, see *Sumbul.* Dose, from twenty minims to a fluidrachm (1·2–3·75 C.c.).

TINCTURA TOLUTANA. U. S., Br. Tincture of Tolu.

(TĬNC-TŪ'RĄ TŌ-LŪ-TĀ'NĄ.)

Tincture of Balsam of Tolu; Teinture de Baume de Tolu, *Fr.;* Tolubalsamtinktur, *G.*

"Balsam of Tolu, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Add the Balsam of Tolu to *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol, and macerate until it is dissolved; then filter through paper, adding, through the filter, enough Alcohol to make the tincture measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Balsam of Tolu, 2 *ounces* (Imperial) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity.* Place the Balsam of Tolu in *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; set aside in a closed vessel; agitate occasionally; when the Balsam is dissolved, filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The British tincture (1898) has been reduced 20 per cent. in the proportion of balsam, and is now of the same strength as the U. S. preparation.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in *chronic bronchitis;* but the proportion of alcohol is too large to allow of its advantageous use in some cases. The dose is one or two fluidrachms (3·75 or 7·5 C.c.). In smaller quantities it is often employed to flavor cough mixtures. It is decomposed by water.

TINCTURA VALERIANÆ. U. S. Tincture of Valerian.

(TĬNC-TŪ'RĄ VĄ-LĒ-RĮ-Ā'NÆ.)

Teinture de Valériane, *Fr.;* Baldriantinktur, *G.*

"Valerian, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

The proportion of alcohol was increased in the U. S. 1890 tincture, to prevent precipitation: the menstruum is now three parts of alcohol to one part of water. The tincture possesses the properties of valerian, but cannot be given in some cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. The dose is from one to four fluidrachms (3·75–15 C.c.). It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (*Ménière.*)

TINCTURA VALERIANÆ AMMONIATA. U. S., Br. Ammoniated Tincture of Valerian.

(TĬNC-TŪ'RĄ VĄ-LĒ-RĮ-Ā'NÆ ĄM-MŌ-NĮ-Ā'TĄ.)

Tinctura Valerianæ Composita; Teinture de Valériane ammoniacale, *Fr.;* Ammoniakalische Baldriantinktur, *G.*

"Valerian, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Aromatic Spirit of Ammonia, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Aromatic Spirit of Ammonia, and macerate for twenty-four hours, in a closed vessel; then pack it firmly in a cylindrical glass percolator, and gradually pour Aromatic Spirit of Ammonia upon it, keeping the percolator well covered, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Valerian Rhizome, in No. 40 powder, 4 *ounces* (Imperial) or 200 grammes; Oil of Nutmeg, 30 *minims* or 3·1 cubic centimetres; Oil of Lemon, 20 *minims* or 2·1 cubic centimetres; Solution of Ammonia, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), 18 *fl. ounces* (Imp. meas.) or 900 cubic centimetres. Mix the liquid ingredients, and prepare by the maceration process." *Br.*

The proportion of valerian was increased 60 per cent. in the Br. Pharm. 1898, and the aromatic spirit of ammonia replaced by alcohol, solution of ammonia, and volatile oils.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical action. The quantity of valerian was very judiciously increased one-third in the U. S. revision of 1880. The tincture is employed as an antispasmodic in *hysteria* and other *nervous affections.* The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.), and should be given in sweetened water, milk, or some mucilaginous fluid.

TINCTURA VANILLÆ. U. S. Tincture of Vanilla.

(TĬNC-TŪ'RĄ VĄ-NĬL'LÆ.)

"Vanilla, cut into small pieces and bruised, *one hundred grammes* [or 3 ounces av., 231 grains]; Sugar, in coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix Alcohol and Water in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Macerate the Vanilla in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of this mixture for twelve hours, then drain off the liquid, and set it aside. Transfer the Vanilla to a mortar, beat it with the Sugar into a uniform powder, then pack it in a percolator, and pour upon it the reserved liquid. When this has disappeared from the surface, gradually pour on menstruum, and continue the percolation, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

This tincture will be easily recognized as the so-called *fluid extract of vanilla.* The object of the preliminary maceration of the cut vanilla is to soften it, so that it may be easily disintegrated when beaten up with the sugar; if the details of the above process be carefully carried out and the alcohol be deodorized, a very satisfactory preparation will result. It is used as a flavoring agent, also to make *vanilla syrup*, by adding one ounce of the tincture to sufficient syrup to make one pint.

TINCTURA VERATRI VIRIDIS. U. S. Tincture of Veratrum Viride.

(TĬNC-TŪ'RĄ VĘ-RĀ'TRĪ VĬR'Į-DĬS.)

Tincture of Green Hellebore; Tincture of American Hellebore.

"Veratrum Viride, in No. 60 powder, *four hundred grammes* [or 14 ounces av., 48 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

The U. S. tincture of American hellebore of 1870 was of the same strength as Dr. Norwood's tincture, which, when prepared by its author, was supposed to be saturated. This may be true of certain ingredients of the root, though probably not in reference to the active principle or principles which it may contain. The present tincture is about one-tenth weaker. The

commencing dose should not exceed from three to eight minims (0·18–0·5 C.c.). The British tincture (1885) was much weaker, the proportion of the root to the menstruum being in the American tincture about as one in two, in the British about as one in five.

TINCTURA ZINGIBERIS. U. S., Br. Tincture of Ginger.

(TĬNC-TŪ'RĄ ZĮN-ĢĬB'Ę-RĬS.)

Teinture de Gingembre, *Fr.;* Ingwertinktur, *G.*

"Ginger, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the Ginger with *fifty cubic centimeters* [or 1 fluidounce, 331 grains] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." *U. S.*

"Ginger, in No. 40 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The strength of this tincture was reduced at the 1880 revision one-third, to bring it into the 20-per cent. class: this is not a disadvantage, however, in view of the introduction of the fluid extract, and the dose is not now inconveniently large.

The tincture of the British Pharmacopœia, though more than twice as strong as was that of the London and Edinburgh Colleges, is still too weak in the proportion of ginger. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. Official Jamaica ginger only should be used; for, whilst a darker-colored preparation is made when the inferior varieties are substituted, the apparent increase in strength is due to coloring matter, and not to the presence of a larger amount of volatile oil or resin.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures in debilitated states of the alimentary canal. The dose is from eight to forty minims (0·5–2·5 C.c.) It is in this country largely used for the preparation of a syrup of ginger, for which purpose, however, the fluid extract is official, and is better even than the strong tincture of the Br. Pharmacopœia 1885, which was dropped at the 1898 revision.

TRAGACANTHA. U. S., Br. Tragacanth.

(TRĂG-Ą-CĂN'THĄ.)

"A gummy exudation from Astragalus gummifer, Labillardière, and from other species of Astragalus (nat. ord. Leguminosæ)." *U. S.* "A gummy exudation obtained by incision from Astragalus gummifer, Labill., and some other species of Astragalus, Linn. Known in commerce as Syrian tragacanth." *Br.*

Gummi Tragacantha; Gomme Adraganthe, *Fr.;* Tragant, Traganth, *G.;* Dragante, *It.;* Gomo Tragacanto, *Sp.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. tragacantha* of Linnæus (*A. massiliensis* of Lamarck), which grows in the south of Europe and the north of Africa and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. creticus* of Lamarck) which grows in Crete and Ionia, and on that of Olivier, to *A. verus*, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer* which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Sieber denies that any one of these species yields the official tragacanth, which he ascribes to *A. aristatus*, growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (*Mérat and De Lens.*) Professor Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkestan, one of which proved to be *A. gummifer* of Labillardière, which was said to yield a white variety, and the other a new species, which he called *A. strobiliferus*, and which was said to yield a red and inferior product. The fact seems to be that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble one another that botanists have found some difficulty in distinguishing them. They are very

abundant on the mountains of Asia Minor, and, according to information received by M. J. Léon Soubeiran from M. Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the *A. creticus* of Lamarck. It is in the Anti-Taurus range that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary part, which alone yields juice. This exudes very slowly, flowing at night, and ceasing during the day; and two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion. (*Journ. de Pharm.*, Feb. 1856, 117, and Feb. 1857, 149.) The section Tragacantha of the genus Astragalus includes the principal species which yield gum tragacanth. According to Haussknecht, tragacanth is yielded by the following species of Astragalus: *A. adscendens*, Boiss. et Hausskn. (Southern Persia); *A. leioclados*, Boiss. (in Middle and Western Persia, by Ispahan and Hamadan); *A. brachycalyx*, Fisch. (Kurdistan and Luristan); *A. gummifer*, Labill. (widely distributed from Lebanon to Armenia and in the northern regions of the Euphrates and Tigris); *A. microcephalus*, Willd. (the same as *A. gummifer*, Labill., and also in Asia Minor); *A. pycnocladus*, Boiss. et Hausskn. (particularly in Western Persia); *A. stromatodes*, Bge. (in Achyr Dagh, in Northern Syria); *A. kurdicus*, Boiss. (Aintab). Other species that yield a tragacanth gum are *A. heratensis*, Bge., of the Khorasan Mountains, which yields a gum known as "kutira," and *A. Parnassi*, Boiss., var. *cyllenea*, of the mountains of Peloponnesus.

Properties. Tragacanth is either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish, yellowish-white, or slightly reddish color, marked by parallel lines or ridges, somewhat translucent, and resembling horn in appearance. It is officially described as "in narrow or broad bands, more or less curved or contorted, marked by parallel lines or ridges, white or faintly yellowish, translucent, horn-like, tough, and rendered more easily pulverizable by a heat of 50° C. (122° F.). On treating Tragacanth with water, it swells and gradually forms a gelatinous mass, which is tinged blue by iodine test-solution, and the fluid portion of which is precipitated on the addition of alcohol, but is not colored blue by iodine test-solution." *U. S.* It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar at the temperature of 50° C. (122° F.). Tragacanth has no smell, and very little taste. Its sp. gr. is 1·384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arabic, the other swelling in water, but not dissolving. To separate the soluble from the insoluble part requires agitation with separate portions of water; the solutions are to be decanted and filtered, and the process is to be continued till water ceases to dissolve anything. Von Sandersleben found that when heated with dilute acids tragacanth acquired reducing properties, and formed, along with much syrup, *arabinose*, which crystallized. (Tollens, *Handbuch der Kohlenhydrate*, 1888, 218.) The explanation of this observation, now generally accepted, is that in tragacanth, like some other gums, part of the arabic acid is present in soluble form, mostly combined with bases, while another part is present in insoluble form, and is known as *traganthin*. This latter, however, under the influence of certain enzymes, is converted into the soluble form. (Lippmann, *Chemie der Zuckerartem*, 2te Auf., 1895, 925.) Examined by Dr. Kützing by means of the microscope, tragacanth was found to consist of organized cells. (See *A. J. P.*, xxv. 37.) In conformity with this statement is the remarkable fact, discovered by Hugo von Mohl and confirmed by Wigand, that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith and those of the medullary rays which traverse the ligneous part of the stem and older branches. (*Ibid.*, xxxi. 243.)

It is stated by Mr. S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania, which, as they are originally of a dark color and destitute of the flaky form of the genuine gum, are broken into small fragments and whitened by means of lead carbonate before being mixed with the tragacanth. Mr. Hanbury states, in confirmation of this, that he has detected lead in the *small tragacanth* imported into London. (*P. J. Tr.*, xv. 20.)

Medical Properties and Uses. Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water

renders it useful for the suspension of heavy insoluble powders; and it is also employed in pharmacy to impart consistence to troches, for which it answers better than does gum arabic.

TRITICUM. U. S. Triticum. [Couch-grass.]

(TRĬT'Ĭ-CŬM.)

"The rhizome of Agropyrum repens (Linné), Beauvois (nat. ord. Gramineæ), gathered in the spring and deprived of the roots." *U. S.*

Rhizoma Graminis, *P. G.;* Radix Graminis, Couch-grass, Quick-grass, Quitch, Dog-grass; Chiendent, Petit Chiendent, *Fr.;* Queckenwurzel, Grasswurzel, *G.*

Agropyrum repens. Linn. This grass, originally a native of Europe, now abounds in meadows and cultivated grounds in the Northern United States, where it is often very troublesome as a weed. It is specifically characterized by its creeping rootstock, by its awns being absent or not more than half the length of the flower, and by its rough flat leaves.

Properties. Couch-grass is officially described as follows. "Very long and creeping, about 2 Mm. thick; as met with in the shops, cut into sections about 1 Cm. long; smooth, but wrinkled; hollow in the centre, straw-yellow; inodorous; taste sweetish." *U. S.*

Medical Properties. Triticum is never exhibited for the purpose of affecting the general system, but only for its influence upon the genito-urinary organs. It is much used by some surgeons in *irritable bladder*, and also in *cystitis*. It is one of the least stimulant of the remedies of its class, and may be employed very freely. In Europe its decoction is said to be used to a considerable extent as a diluent and slightly nutritious drink. It may be taken *ad libitum*, or the fluid extract may be given in doses of a fluidrachm (3·75 C.c.) every three hours in five or six ounces of water.

TRITURATIONES. U. S. Triturations.

(TRĬT-Ū-RĀ-TĮ-Ō'NĒŞ—trĭt-yu-rā-shę-ō'nēz.)

"Unless otherwise directed, Triturations are to be prepared by the following formula. Take of The Substance, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the Substance and the Sugar of Milk, separately; then place the Substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal measure of Sugar of Milk, mix well by means of a spatula, and triturate them thoroughly together. Then add fresh portions of the Sugar of Milk, from time to time, until the whole is added, and continue the trituration until the Substance is intimately mixed with the Sugar of Milk and reduced to a fine powder." *U. S.*

This general formula has been introduced into the Pharmacopœia in order that a definite and uniform method be authorized of making a class of powders which has come into use in various sections of our country. Whilst the necessity of giving recognition to the class may be questioned by many, the importance of securing uniformity in composition is evident.

TRITURATIO ELATERINI. U. S. (Br.) Trituration of Elaterin.

(TRĬT-Ū-RĀ'TĮ-Ō ĔL-Ą-TĘ-RĪ'NĪ.)

Pulvis Elaterini Compositus, *Br.*, Compound Powder of Elaterin.

"Elaterin, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them thoroughly by trituration." *U. S.*

"Elaterin, 5 *grains* or 1 gramme; Milk Sugar, 195 *grains* or 39 grammes. Triturate in a mortar until a fine powder is produced." *Br.*

The Br. Pharm. 1898 added the Compound Powder of Elaterin to the list of powders. It is identical with the Trituration of Elaterin, except in strength. The U. S. Pharm. trituration contains 10 per cent. of elaterin, the British powder 2½ per cent.

This is probably the best representative of the class of triturations that could be selected for introduction into the national authority. Elaterium is at the best a substance of variable quality, whilst the active principle is a definite product, and accurate dosage can be secured more effectually through the use of this trituration than by the employment of commercial elaterium. The dose is from one-half to five-eighths of a grain (0·03–0·04 Gm.). The dose of the British powder is from one to four grains (0·065–0·27 Gm.).

TROCHISCI. Troches.

(TRŌ-ʛHĪS'CĪ—trǫ-kīs'sī.)

Tabellæ; Lozenges; Tablettes, Pastilles, *Fr.;* **Pastillen, Zeltchen,** *G.*

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities and which are destitute of any very disagreeable flavor. They were formerly much more used and more skilfully prepared in Europe than in this country, but at present those manufactured here are fully equal to the imported lozenges. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues.* A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now dusted with sugar and starch, and the mass is divided into small cakes by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying-room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in boxes. Lozenges may be prepared from almost any medicine which it is advisable to administer in this form. The following general formula may be found useful. Take of citric acid, in powder, a drachm; powdered sugar eight ounces; oil of lemon twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. Lozenges are sometimes made by saturating blank lozenges with aromatic spirits. Currant paste or jelly has come into use of late years largely as a basis for troches.* Lozenges of a cylindrical shape are extensively used, having a basis of

* *Currant Paste Lozenges.* These lozenges have been largely employed. They were introduced by Dr. Morell Mackenzie, Senior Physician to the London Hospital for Diseases of the Throat, and differ from ordinary lozenges in the use as a basis of currant paste (or jelly), of which they contain from 70 to 80 per cent.; this may usually be obtained from wholesale confectioners or grocers.

Trochisci Acidi Benzoici. Benzoic Acid, in powder, 175 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Mix the dry ingredients; then add the Red Currant Paste until the whole mass weighs 1 pound; divide into 350 lozenges of 20 grains each, and dry them in a hot-air chamber at a moderate heat. Each lozenge contains about one-half grain of Benzoic Acid, and is marked B. A. Dose, one lozenge every four hours. If used as a "voice lozenge," one should be taken a quarter of an hour before using the voice.

Trochisci Acidi Carbolici. Pure Carbolic Acid, 350 grains; Gum Acacia, in powder, 220 grains; Refined Sugar, in powder, 5468 grains (12½ ounces); Mucilage of Gum Acacia, 1 ounce; Distilled Water, as much as is sufficient. Mix the Carbolic Acid with the powders, add the Mucilage and Water to form a mass weighing 1 pound, and divide into 350 lozenges and dry them in a hot-air chamber at a moderate heat. Each lozenge contains about one grain of Carbolic Acid, and is marked C. A. Dose, one lozenge four or five times daily. Use, antiseptic and stimulant.

Trochisci Acidi Tannici. Tannic Acid, in powder, 525 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 1½ grains of Tannic Acid, and is marked T. Dose, one lozenge every three or four hours.

Trochisci Aconiti. Tincture of Aconite (B. P.), 175 minims; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*). Each lozenge contains the equivalent of half a minim of Tincture of Aconite (B. P.) (or quarter of a minim, U. S. P.), and is marked A. C. Dose, one lozenge every half-hour or hour. Use, in tonsillitis and febrile affections of the throat.

Trochisci Althææ. Powdered decorticated Marshmallow Root, 400 grains; Refined Sugar, in powder, ¾ pound; Gum Acacia, in powder, ½ pound; Orange Flower Water and White of Egg, as much as is sufficient to make into 350 soft lozenges. Macerate the Marshmallow Root in a sufficient quantity of Orange Flower Water for 12 hours, strain, then add the Gum Acacia and Sugar; dissolve, and evaporate to the consistence of honey with constant stirring; add gradually the White of Egg beaten up with more Orange Flower Water. Evaporate, with stirring, till the paste will not adhere to the hand; then divide into lozenges. Dose, one lozenge every half-hour or hour. Use, emollient. Valuable after excision of tonsils or uvula.

Trochisci Ammonii Chloridi. Ammonium Chloride, in powder, 700 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains about 2 grains of Ammonium Chloride, and is marked M. A. Dose, one lozenge every three hours.

Trochisci Boracis. Borax, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 3 grains of Borax, and is marked B. O. Dose, one lozenge every three or four hours.

Trochisci Catechu. Pale Catechu, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Ben-*

liquorice, gum, and sugar, and the manufacture of these is now an important industry. Franklin C. Hill devised an improved machine for making Liquorice and Wistar's Lozenges. (See *A. J. P.*, 1874, 401.) For Slocum's and Harrison's improved forms of lozenge boards, rollers, etc., see *A. J. P.*, 1879, 589; 1880, 255. Mr. A. D. Marcy figured an instrument for shaping troches in *N. R.*, Feb. 1882. The Br. Pharm. 1898 adopted four bases for lozenges, as follows: fruit basis, rose basis, simple basis, and tolu basis. It will be noticed that in the British formulas the quantity of active ingredients for each lozenge is stated and the kind of basis indicated. This is done merely to avoid repetition.

"PREPARATION WITH FRUIT BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *fifteen and a half ounces* (Imperial) or four hundred and thirty-nine and a half grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *one fluid ounce and a quarter* (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and *two ounces* (Imp.) or fifty-six and three-quarter grammes of the black-currant paste of commerce previously softened with boiling Distilled Water, adding any additional Distilled Water that may be necessary. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

"PREPARATION WITH ROSE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *seventeen and a half ounces* (Imperial) or four hundred and ninety-six grammes

zoici.) Each lozenge contains 2 grains of Catechu, and is marked C. T. Dose, one lozenge every three hours. Use, astringent, but less powerful than the Tannin.

Trochisci Cubebæ. Cubebs, in powder, 200 grains; Extract of Liquorice, 1225 grains; Tragacanth, in powder, 70 grains; Refined Sugar, 200 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains about one-half grain of Cubebs, and is marked C. B. Dose, one lozenge every three or four hours. Use, very serviceable in diminishing excessive secretion of mucus from pharynx, larynx, or trachea. These lozenges closely resemble the *Brown's Bronchial Troches*, but Black Currant Paste is employed, and less gum and sugar.

Trochisci Guaiaci. Guaiacum Resin, in powder, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 2 grains of Guaiacum, and is marked G. Dose, one lozenge every two hours in acute inflammation; three times a day in chronic affections. Use, a specific for arresting crescent inflammation of the tonsils, and useful both in acute and subacute inflammation of the pharynx, and in acute follicular disease of the tonsils, etc.

Trochisci Kino. Kino, in powder, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 2 grains of Kino, and is marked K. Dose, one lozenge every three or four hours. Use, astringent; rather less powerful than Rhatany.

Trochisci Krameriæ. Extract of Rhatany, in powder, 1050 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Mix and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 3 grains of Extract of Rhatany, and is marked R. Dose, one lozenge every three or four hours. Use, a very useful astringent. Rhatany does not disagree with the stomach, as is often the case with Tannic Acid, nor does it cause constipation to the same extent as Kino or Catechu.

Trochisci Lactucæ. Extract of Lettuce, 350 grains; Tragacanth, in powder, 100 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 1 grain of Extract of Lettuce, and is marked L. Dose, one lozenge every hour or two. Use, soothing and mildly sedative.

Trochisci Potassii Chloratis. Potassium Chlorate, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 3 grains of Potassium Chlorate, and is marked P. Dose, one lozenge every three or four hours. Use, stimulant and antiseptic. Useful in thrush and aphthous ulceration.

Trochisci Potassii Citratis. Potassium Citrate, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 3 grains of Potassium Citrate, and is marked C. P. Dose, one lozenge every three or four hours. Use, topical sialagogue.

Trochisci Potassii Tartratis Acidæ. Acid Potassium Tartrate, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 3 grains of Acid Potassium Tartrate, and is marked T. P. Dose, one lozenge every two or three hours. Use, topical sialagogue.

Trochisci Pyrethri. Pellitory Root, in powder, 350 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains 1 grain of Pellitory, and is marked P. Y. Dose, one lozenge every two or three hours. Use, a very valuable sialagogue.

Trochisci Sedativi. Extract of Opium, in powder, 35 grains; Tragacanth, in powder, 100 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici.*) Each lozenge contains one-tenth grain of Extract of Opium, and is marked S. Dose, one lozenge every three or four hours. Use, sedative, for irritative coughs and painful conditions of the pharynx. (From the *Pharmacopœia of the Hospital for the Diseases of the Throat*, 4th ed., 1881.)

of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *five fluid drachms* (Imp. meas.) or seventeen and a half cubic centimetres of Mucilage of Gum Acacia and a sufficient quantity of the official Rose Water. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

"PREPARATION WITH SIMPLE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *seventeen and a half ounces* (Imperial) or four hundred and ninety-six grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *one fluid ounce and a quarter* (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

"PREPARATION WITH TOLU BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve what salts of alkaloids may be ordered in *three fluid drachms* (Imperial measure) or ten and a half cubic centimetres of Distilled Water; mix the solution intimately with *seventeen ounces* (Imp.) or four hundred and eighty-two grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Thoroughly incorporate with the mixture any other drugs ordered for the lozenges, and *three fluid drachms* (Imp. meas.) or ten and a half cubic centimetres of Tincture of Balsam of Tolu. Make into a paste with *one fluid ounce and a quarter* (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and any additional Distilled Water that may be necessary. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

TROCHISCUS ACIDI BENZOICI. Br. Benzoic Acid Lozenge.

(TRŌ-ϕHĬS'CŬS ĂÇ'Ĭ-DĪ BĔN-ZŌ'Ĭ-CĪ.)

"Benzoic Acid, ½ *grain* or 0·0324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

TROCHISCUS ACIDI CARBOLICI. Br. Phenol Lozenge.

(TRŌ-ϕHĬS'CŬS ĂÇ'Ĭ-DĪ CĂR-BŎL'Ĭ-CĪ.)

"Phenol, 1 *grain* or 0·0648 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See above.)

TROCHISCI ACIDI TANNICI. U. S. (Br.) Troches of Tannic Acid.

[Tannin Lozenges.]

(TRŌ-ϕHĬS'CĪ ĂÇ'Ĭ-DĪ TĂN'NĬ-CĪ.)

Trochiscus Acidi Tannici, *Br.;* **Pastilles de Tannin,** *Fr.;* **Tanninpastillen,** *G.*

"Tannic Acid, *six grammes* [or 93 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Stronger Orange Flower Water, *a sufficient quantity*, To make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into *one hundred troches.*" *U. S.*

"Tannic Acid, ½ *grain* or 0·0324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

These are useful in *relaxation of the uvula*, and in *chronic angina*, being allowed slowly to dissolve in the mouth. Each U. S. troche contains about one grain (0·06 Gm.) of the acid.

TROCHISCI AMMONII CHLORIDI. U. S. Troches of Ammonium Chloride.

(TRŌ-ϕHĬS'CĪ ĄM-MŌ'NĮ-Ī ϕHLŌ'RĮ-DĪ.)

Pastilles de Chlorure d'Ammonium, *Fr.;* **Chlorammoniumpastillen,** *G.*

"Ammonium Chloride, in fine powder, *ten grammes* [or 154 grains]; Extract of Glycyrrhiza, in fine powder, *twenty-five grammes* [or 386 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Sugar, in fine powder, *fifty grammes* [or 1 ounce av., 334 grains]; Syrup of

Tolu, *a sufficient quantity*, To make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then, with Syrup of Tolu, form a mass, to be divided into *one hundred troches*." *U. S.* Each troche contains about one and a half grains (0·10 Gm.) of ammonium chloride.

These troches are largely used in *congested conditions of the pharynx and larynx*.

TROCHISCUS BISMUTHI COMPOSITUS. Br. Compound Bismuth Lozenge.

(TRŌ-ȹHĬS'CŬS BĬŞ-MŪ'THĪ CǪM-PŌŞ'Ị-TŬS.)

Troches of Bismuth; Pastilles de Sous-nitrate de Bismuth, *Fr.;* **Wismuthpastillen,** *G.*

"Bismuth Oxycarbonate, 2 *grains* or 0·1296 gramme; Heavy Magnesium Carbonate, 2 *grains* or 0·1296 gramme; Precipitated Calcium Carbonate, 4 *grains* or 0·2592 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1413.)

These may be used to obtain the effects of bismuth subnitrate on the stomach, as well as of the magnesium and calcium carbonates as an antacid, two or more being administered for a dose. They may also be found useful in *chronic inflammation of the throat and œsophagus*.

TROCHISCI CATECHU. U. S. (Br.) Troches of Catechu.

(TRǪ-ȹHĬS'CĪ CĂT'Ę-ȹHŪ.)

Trochiscus Catechu, *Br.,* **Catechu Lozenge; Tabellæ cum Catechu,** *F. P.;* **Pastilles de Cachou,** *Fr.;* **Katechu-pastillen,** *G.*

"Catechu, in fine powder, *six grammes* [or 93 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Stronger Orange Flower Water, *a sufficient quantity*, To make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into *one hundred troches*." *U. S.*

"Catechu, 1 *grain* or 0·0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1414.)

These, like the troches of tannic acid, are useful in *prolapsus of the uvula*, and in other forms of *relaxation of the fauces*, and may also be used, in the number of three or more at a dose, to obtain the effects of catechu on the *primæ viæ* and on the system. Each troche contains about one grain (0·06 Gm.) of catechu, and the taste is not disagreeable.

TROCHISCI CRETÆ. U. S. Troches of Chalk.

(TRǪ-ȹHĬS'CĪ CRĒ'TÆ.)

Pastilles de Craie préparée, *Fr.;* **Kreidepastillen,** *G.*

"Prepared Chalk, *twenty-five grammes* [or 386 grains]; Acacia, in fine powder, *seven grammes* [or 108 grains]; Spirit of Nutmeg, *three cubic centimeters* [or 49 minims]; Sugar, in fine powder, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity*, To make *one hundred troches*. Rub the powders with the Spirit of Nutmeg until they are thoroughly mixed; then, with Water, form a mass, to be divided into *one hundred troches*." *U. S.*

These troches contain each about four grains (0·25 Gm.) of chalk, and are used as a gentle, astringent antacid in *diarrhœa*. They deserve to be used more frequently than they have been, being well adapted for children.

TROCHISCI CUBEBÆ. U. S. Troches of Cubeb.

(TRǪ-ȹHĬS'CĪ CŪ-BĒ'BÆ.)

Pastilles de Cubèbe, *Fr.;* **Kubebenpastillen,** *G.*

"Oleoresin of Cubeb, *four grammes* [or 61 grains]; Oil of Sassafras, *one cubic centimeter* [or 16 minims]; Extract of Glycyrrhiza, in fine powder, *twenty-five grammes* [or 386 grains]; Acacia, in fine powder, *twelve grammes* [or 185 grains]; Syrup of Tolu, *a sufficient quantity*, To make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then add the Oleoresin and the Oil, and incorporate them with the mixture. Lastly, with Syrup of Tolu, form a mass, to be divided into *one hundred troches*." *U. S.*

Each lozenge contains half a minim (0·04 Gm.) of the oleoresin of cubeb, being about half the strength of the troche of 1870. The preparation is intended chiefly for effect upon the fauces and other parts of the upper alimentary passages, and may be used advantageously in some cases of *chronic cough*, and in *ulceration* or *chronic inflammation of the fauces*. The proportion of oleoresin of cubeb might be decreased again with great benefit.

TROCHISCUS EUCALYPTI GUMMI. Br. Eucalyptus Gum Lozenge.

(TRŌ-ϕHĬS'CŬS EŪ-CĄ-LĬP'TĪ GŬM'MĪ.)

"Eucalyptus Gum, 1 *grain* or 0·0648 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

TROCHISCI FERRI. U. S. Troches of Iron.

(TRŌ-ϕHĬS'CĪ FĔR'RĪ.)

Pastilles d'Oxide de Fer, *Fr.;* Eisenoxydpastillen, *G.*

"Ferric Hydrate, dried at a temperature not exceeding 80° C. (176° F.), *thirty grammes* [or 1 ounce av., 25 grains]; Vanilla, cut into slices, *one gramme* [or 15 grains]; Sugar, in fine powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Mucilage of Tragacanth, *a sufficient quantity*, To make *one hundred troches.* Rub the Vanilla, first, with a portion of the Sugar to a uniform powder, and afterwards with the Ferric Hydrate and the remainder of the Sugar, until they are thoroughly mixed. Then, with Mucilage of Tragacanth, form a mass, to be divided into *one hundred troches.*" *U. S.*

Each lozenge contains about five grains (0·3 Gm.) of ferric hydrate, and from one to six may be given, according to the effects desired. (See *Ferri Oxidum Hydratum.*)

TROCHISCUS FERRI REDACTI. Br. Reduced Iron Lozenge.

(TRŌ-ϕHĬS'CŬS FĔR'RĪ RĘ-DĂC'TĪ.)

Pastilles de Fer, Tablettes chalybées, *Fr.;* Eisenpastillen, *G.*

"Reduced Iron, 1 *grain* or 0·0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1414.)

From one to five of the lozenges may be taken for a dose.

TROCHISCI GLYCYRRHIZÆ ET OPII. U. S. Troches of Glycyrrhiza and Opium.

(TRŌ-ϕHĬS'CĪ GLĬÇ-ŲR-RHĪ'ZÆ ĔT Ō'PĮ-Ī.)

Pastilles d'Opium, Pastilles de Réglisse opiacées, *Fr.;* Opiumpastillen, *G.*

"Extract of Glycyrrhiza, in fine powder, *fifteen grammes* [or 231 grains]; Powdered Opium, *one-half gramme* [or 8 grains]; Acacia, in fine powder, *twelve grammes* [or 185 grains]; Sugar, in fine powder, *twenty grammes* [or 309 grains]; Oil of Anise, *two-tenths of a cubic centimeter* [or 3 minims]; Water, *a sufficient quantity*, To make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then add the Oil of Anise (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with Water, form a mass, to be divided into *one hundred troches.*" *U. S.*

The British Pharm. 1898 no longer recognizes lozenges containing liquorice and opium; the Br. 1885 process is appended.*

A preparation similar to the above is much used in Philadelphia and elsewhere under the name of *Wistar's cough lozenges.* Sometimes morphine sulphate is substituted in equivalent proportion for the opium, and occasionally a little tartar emetic is added; but these modifications of the official formula are not admissible without a change of title. Each U. S. troche contains about one-twelfth of a grain of powdered opium, the English each one-tenth of a grain of extract of opium. These troches are demulcent and anodyne, and useful in allaying *cough.*

TROCHISCUS GUAIACI RESINÆ. Br. Guaiacum Resin Lozenge.

(TRŌ-ϕHĬS'CŬS GUĀ'IĄ-CĪ RĘ-ŞĪ'NÆ.)

"Guaiacum Resin, 3 *grains* or 0.1944 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

* *Trochisci Opii, Br.* 1885. *Opium Lozenges.* "Take of Extract of Opium *seventy-two grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *sixteen ounces* [avoirdupois]; Gum Acacia, in powder, *two ounces* [av.]; Extract of Liquorice *six ounces* [av.]; Distilled Water *a sufficiency.* Add the Extract of Opium, first softened by means of a little Water, and the Tincture of Tolu, to the Extract of Liquorice heated in a water-bath. When the mixture is reduced to a proper consistence, remove it to a slab, add the Sugar and Gum previously rubbed together, and mix thoroughly. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one-tenth of a grain of Extract of Opium, equivalent to one-fiftieth of a grain of morphine." *Br.* 1885.

TROCHISCI IPECACUANHÆ. U. S. (Br.) Troches of Ipecac.

(TRŌ-ĶHĬS'CĪ ĬP-Ē-CĂC-Ū-ĂN'HÆ.)

Trochiscus Ipecacuanhæ, *Br.*, Ipecacuanha Lozenges; Pastilles d'Ipécacuanha, *Fr.;* Brechwurzelpastillen, *G.*

"Ipecac, in No. 60 powder, *two grammes* [or 31 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Syrup of Orange, *a sufficient quantity*, To make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then, with Syrup of Orange, form a mass, to be divided into *one hundred troches*." *U. S.*

"Ipecacuanha Root, in powder, ½ *grain* or 0·0162 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

These are useful expectorant lozenges in *catarrhal complaints*. Each of the U. S. lozenges contains about one-third of a grain (0·021 Gm.) of ipecac.

TROCHISCI KRAMERIÆ. U. S. (Br.) Troches of Krameria.

(TRŌ-ĶHĬS'CĪ KRĄ-MĒ'RĮ-Æ.)

Trochiscus Krameriæ, *Br.*, Krameria Lozenge, Rhatany Lozenge; Pastilles de Ratanhia, *Fr.;* Ratanhapastillen, *G.*

"Extract of Krameria, *six grammes* [or 93 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Stronger Orange Flower Water, *a sufficient quantity*, To make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into *one hundred troches*." *U. S.*

"Extract of Krameria, 1 *grain* or 0·0648 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

These are astringent troches, which may be used in *chronic angina*.

TROCHISCUS KRAMERIÆ ET COCAINÆ. Br. Krameria and Cocaine Lozenge. [Rhatany and Cocaine Lozenge.]

(TRŌ-ĶHĬS'CŬS KRĄ-MĒ'RĮ-Æ ĔT CŌ-CĄ-Ī'NÆ.)

"Extract of Krameria, 1 *grain* or 0·0648 gramme; Cocaine Hydrochloride, $\frac{1}{20}$ *grain* or 0·00324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1413.)

TROCHISCI MENTHÆ PIPERITÆ. U. S. Troches of Peppermint.

(TRŌ-ĶHĬS'CĪ MĔN'THÆ PĪ-PĘ-RĪ'TÆ.)

Pastilles de Menthe anglaises, *Fr.;* **Pfefferminzpastillen**, *G.*

"Oil of Peppermint, *one cubic centimeter* [or 16 minims]; Sugar, in fine powder, *eighty grammes* [or 2 ounces av., 360 minims]; Mucilage of Tragacanth, *a sufficient quantity*, To make *one hundred troches*. Rub the Oil of Peppermint and the Sugar together until they are thoroughly mixed; then, with Mucilage of Tragacanth, form a mass, to be divided into *one hundred troches*." *U. S.*

Useful in *slight gastric or intestinal pains*, *nausea*, and *flatulence*.

TROCHISCUS MORPHINÆ. Br. Morphine Lozenge.

(TRŌ-ĶHĬS'CŬS MÖR-PHĪ'NÆ.)

Pastilles de Morphine, *Fr.;* **Morphinpastillen**, *G.*

"Morphine Hydrochloride, $\frac{1}{36}$ *grain* or 0·0018 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See p. 1414.)

Useful for alleviating *cough*, and for other purposes which are answered by minute doses of morphine, of the hydrochloride of which each lozenge contains about one-thirty-sixth of a grain (0·0018 Gm.).

TROCHISCI MORPHINÆ ET IPECACUANHÆ. U. S. (Br.) Troches of Morphine and Ipecac.

(TRŌ-ĶHĬS'CĪ MÖR-PHĪ'NÆ ĔT ĬP-Ē-CĂC-Ū-ĂN'HÆ.)

Trochiscus Morphinæ et Ipecacuanhæ, *Br.*, Morphine and Ipecacuanha Lozenge; Pastilles de Morphine et d'Ipécacuanha, *Fr.:* Morphinpastillen mit Brechwurzel, *G.*

"Morphine Sulphate, *sixteen centigrammes* [or 2½ grains]; Ipecac, in No. 60 powder, *fifty centigrammes* [or 8 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Oil of Gaultheria, *two-tenths of a cubic centimeter* [or 3 minims]; Mucilage of Trag-

acanth, *a sufficient quantity*, To make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then add the Oil of Gaultheria (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with Mucilage of Tragacanth, form a mass, to be divided into *one hundred troches.*" *U. S.*

"Morphine Hydrochloride, $\frac{1}{36}$ *grain* or 0·0018 gramme; Ipecacuanha Root, in powder, $\frac{1}{72}$ *grain* or 0·0054 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See p. 1414.)

Expectorant and anodyne, useful especially in *allaying cough.* The U. S. and the Br. lozenges each contain respectively one-fortieth of a grain (0·0016 Gm.) and one-thirty-sixth of a grain (0·0018 Gm.) of morphine salt, and one-twelfth of a grain (0·005 Gm.) of ipecacuanha.

TROCHISCI POTASSII CHLORATIS. U. S. (Br.) Troches of Potassium Chlorate.

(TRŌ-ȹHĪS'CĪ PŌ-TĂS'SI-Ī ȹHLŌ-RĀ'TIS.)

Trochiscus Potassii Chloratis, *Br.,* Chlorate of Potash Lozenges; Pastilles de Chlorate de Potasse, *Fr.;* Pastillen von Chlorsaurem Kali, *G.*

"Potassium Chlorate, in fine powder, *thirty grammes* [or 1 ounce av., 25 grains]; Sugar, in fine powder, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Tragacanth, in fine powder, *six grammes* [or 93 grains]; Spirit of Lemon, *one cubic centimeter* [or 16 minims]; Water, *a sufficient quantity*, To make *one hundred troches.* Mix the Sugar with the Tragacanth and the Spirit of Lemon by trituration, in a mortar; then transfer the mixture to a sheet of paper, and, by means of a bone spatula, mix with it the Potassium Chlorate, being careful, by avoiding trituration or pressure, to prevent the mixture from igniting or exploding. Lastly, with Water, form a mass, to be divided into *one hundred troches.*" *U. S.*

"Potassium Chlorate, 3 *grains* or 0·1944 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1413.)

These lozenges are very largely employed, and are locally useful in cases of *sore throat.* If dissolved slowly in the mouth they may be used almost continuously.

TROCHISCI SANTONINI. U. S. (Br.) Troches of Santonin.

(TRŌ-ȹHĪS'CĪ SĂN-TŌ-NĪ'NĪ.)

Trochiscus Santonini, *Br.;* Pastilles de Santonine, *Fr.;* Santoninpastillen, *G.*

"Santonin, in fine powder, *three grammes* [or 46 grains]; Sugar, in fine powder, *one hundred and ten grammes* [or 3 ounces av., 385 grains]; Tragacanth, in fine powder, *three grammes* [or 46 grains]; Stronger Orange Flower Water, *a sufficient quantity*, To make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into *one hundred troches.* Troches of Santonin should be kept in dark, amber-colored vials." *U. S.*

"Santonin, 1 *grain* or 0·0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1414.)

The United States process is faulty in the direction that the santonin should be in fine powder. The longer the absorption of santonin is delayed in the intestines the more prolonged and consequently the more effective is its vermicidal influence. As soon as it is absorbed it ceases to act upon the worm, and becomes a more or less deleterious substance in the system. A dose of santonin in crystals which is not poisonous may become somewhat toxic when given in fine powder. The proportion of crystals in the lozenge mass (2½ per cent.) is not sufficient to prevent the formation of a good lozenge. Each U. S. lozenge contains about half a grain (0·033 Gm.) of santonin. (See *Santoninum*, p. 1191.) Dose, from one to four lozenges.

TROCHISCI SODII BICARBONATIS. U. S. (Br.) Troches of Sodium Bicarbonate.

(TRŌ-ȹHĪS'CĪ SŌ'DI-Ī BI-CĂR-BŌ-NĀ'TĪS.)

Trochiscus Sodii Bicarbonatis, *Br.:* Trochisci Natri Bicarbonici, *P. G.;* Pastilles de Bicarbonate de Soude, Pastilles de Vichy, Pastilles digestives, *Fr.;* Natronpastillen, *G.*

"Sodium Bicarbonate, *twenty grammes* [or 309 grains]; Sugar, in fine powder, *sixty grammes* [or 2 ounces av., 51 grains]; Nutmeg, bruised, *one gramme* [or 15 grains]; Mucilage of Tragacanth, *a sufficient quantity*, To make *one hundred troches.* Triturate the Nutmeg with the Sugar, gradually added, until they are reduced to a fine powder, and mix this intimately with the Sodium Bicarbonate; then, with Mucilage of Tragacanth, form a mass, to be divided into *one hundred troches.*" *U. S.*

"Sodium Bicarbonate, 3 *grains* or 0·1944 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1413.)

The U. S. troche contains three grains (0·20 Gm.) of the alkaline salt. Antacid and antilithic, useful in *heartburn* and in *uric acid gravel.* From one to six may be given for a dose.

TROCHISCUS SULPHURIS. Br. Sulphur Lozenge.

(TRŌ-ȼHĬS'CŬS SŬL'PHŪ-RĬS.)

"Precipitated Sulphur, 2500 *grains* or 162 grammes; Acid Potassium Tartrate, in powder, 500 *grains* or 32·4 grammes; Refined Sugar, in powder, 4000 *grains* or 259·2 grammes; Gum Acacia, in powder, 500 *grains* or 32·4 grammes; Tincture of Orange, 500 *minims* or 29·5 cubic centimetres; Mucilage of Gum Acacia, 500 *minims* or 29·5 cubic centimetres. Mix the Tincture of Orange with the powders; add the Mucilage of Gum Acacia to form a suitable mass. Divide into five hundred Lozenges. Dry them in a hot-air chamber at a moderate temperature. Each Lozenge contains *five grains* or 0·324 gramme of Precipitated Sulphur." *Br.*

These lozenges were introduced into the "Additions" to the British Pharmacopœia 1885. The dose is from one to six lozenges. (See *Sulphur Præcipitatum*, p. 1310.)

TROCHISCI ZINGIBERIS. U. S. Troches of Ginger.

(TRŌ-ȼHĬS'CĪ ZĮN-ȻĬB'Ę-RĬS.)

Pastilles de Gingembre, *Fr.;* Ingwerpastillen, *G.*

"Tincture of Ginger, *twenty cubic centimeters* [or 325 minims]; Tragacanth, in fine powder, *four grammes* [or 62 grains]; Sugar, in fine powder, *one hundred and thirty grammes* [or 4 ounces av., 256 grains]; Syrup of Ginger, *a sufficient quantity*, To make *one hundred troches.* Mix the Tincture of Ginger with the Sugar, and, having exposed the mixture to the air until dry, reduce it to a fine powder. To this add the Tragacanth, and mix thoroughly. Lastly, with Syrup of Ginger, form a mass, to be divided into *one hundred troches.*" *U. S.*

Each lozenge contains three minims (0·2 C.c.) of the tincture, and they may be taken as required, being especially calculated to relieve *gastric pains* resulting from *flatulence.*

ULMUS. U. S. Elm. [Slippery Elm.]

(ŬL'MŲS.)

"The inner bark of Ulmus fulva, Michaux (nat. ord. Urticaceæ)." *U. S.*

Ulmi Cortex; Ecorce d'Orme, *Fr.;* Ulmenrinde, Rüsterrinde, *G.*

Ulmus fulva. Michaux, *Flor. Bor. Amer.* (1803) i. 172.—*U. rubra.* Michx. f. *Hist. Arb. Am.* iii. 278.—*U. pubescens.* Walt. *Fl. Car.* (1788) 112. The *slippery elm*, called also *red elm*, is a lofty tree, fifty or sixty feet in height, with a trunk fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which appear before the leaves, are sessile, and in clusters at the extremities of the young shoots. The bunches of flowers are surrounded by scales, which are downy like the buds. The calyx also is downy. There is no corolla. The stamens are five, short, and of a pale rose color. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.* The nat. ord. Urticaceæ has been subdivided by Engler and Prantl into three distinct natural orders: (1) the Ulmaceæ, including Ulmus, etc.; (2) the Moraceæ, including Morus, Humulus, Cannabis, etc.; (3) the Urticaceæ proper, including Urtica, etc.

This species of elm is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Alleghany Mountains. It flourishes in open, elevated situations, and requires a firm, dry soil. From the *white elm* (*U. americana*) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark, separated from the epidermis, is the part used. Large quantities are collected in the Lower Peninsula of Michigan.

* *Fremontia californica*, Torr., or *California Slippery Elm*, is not botanically allied to *Ulmus fulva:* its bark is said, however, to have the same properties as slippery-elm bark, and to be used for a similar purpose.

It is in long, nearly flat pieces, from one to two lines thick, of a fibrous texture, a tawny color which is reddish on the inner surface, a peculiar sweetish, not unpleasant odor, and a highly mucilaginous taste when chewed. "The inner surface finely ridged; fracture fibrous and mealy; the transverse section delicately checkered; odor slight, peculiar; taste mucilaginous, insipid." *U. S.* By grinding, it is reduced to a light, grayish fawn-colored powder. It abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of lead acetate and subacetate, but not by alcohol. It contains a variety of tannin which colors iron solutions green, in amount about 6·5 per cent. according to Rink, or, according to Davy, a little less than 3 per cent.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odor of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kind, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to state. Ground slippery-elm bark is often adulterated, usually with substances containing starch. Pure slippery-elm bark should have no starch in it.*

Dr. C. W. Wright, of Cincinnati, in a communication to the *Western Lancet*, states that slippery-elm bark has the property of preserving fatty substances from rancidity, and that this fact was known to the Indians, who prepared bear's fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Dr. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (*A. J. P.*, xxiv.)

Medical Properties and Uses. Slippery-elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in *dysentery*, *diarrhœa*, and *diseases of the urinary passages*. Its mucilage is nutritious; and we are told that it has proved sufficient for the support of life in the absence of other food. The case of a lad of 15 is recorded, who, a day or two after eating a portion of this bark, became violently ill, and died. The stomach was examined, and found full of the bark twisted into balls. The death was no doubt owing to the large amount of indigestible matter in the stomach, and not to any poisonous property of the bark. (*Phila. Med. Times*, Feb. 7, 1874, p. 303.) Dr. J. R. Dowler, of Beardstown, Ill., reports two cases of *tape-worm*, one in a child, the other in an adult, in which the worm was discharged as a consequence of the patients' chewing and swallowing the bark of the elm. (*Bost. Med. and Surg. Journ.*, March 16, 1865, p. 132.) It is commonly used as a drink in the form of infusion. (See *Mucilago Ulmi.*) The powder may be used stirred in hot water, with which it forms a mucilage more or less thick according to the proportion added. The bark also serves as an emollient application in cases of *external inflammation*. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. Dr. McDowell, of Virginia, recommended slippery-elm bark for the dilatation of *fistulas* and *strictures* (*Med. Examiner*, i. 244); subsequently Dr. H. R. Storer, of Boston, used it advantageously for *dilating the os uteri* (*Bost. Med. and Surg. Journ.*, liii. 300), and Dr. A. Abbe, of the same place, succeeded in curing with it a case of *stricture of the rectum* (*Ibid.*, liv. 349).

UNGUENTA. Ointments.

(ŲN-GUĔN′TĄ—ųn-gwĕn′tą.)

Pommades, Onguents, *Fr.;* Salben, *G.*

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with *simple ointment*, *hydrous wool fat*, *lard*, or *petrolatum*, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division before being incorporated with the unctuous matter. If soluble in water or in alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with a little water or alcohol, according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to ran-

* The following test, devised by Mr. Geo. M. Beringer, seems to have practical value. Ten grains of ground or pulverized elm bark, thoroughly shaken with one fluidounce of water, will, if pure and of good quality, in fifteen minutes form a thick jelly-like mass of a good fawn color.

cidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by M. Deschamps (*A. J. P.*, xv. 260); but care should be taken that there be no therapeutic objection to the admixture.* Elm bark is said to have the same effect. (See p. 1420.) According to Dr. Geisler, ten drops of spirit of nitrous ether, incorporated with an ounce of ointment, will overcome the disagreeable fatty odor. (*Pharm. Centralbl.*, 1847, 927.) Hydrous wool fat or lanolin, petrolatum, and glycerite of starch are now used as bases for ointments. (See *Adeps Lanæ Hydrosus*, *Petrolatum*, and *Glyceritum Amyli.*) In the selection of a vehicle for an ointment it is important to consider the object for which the ointment is to be used. Lanolin is a natural emollient of the skin, composed of cholesterin and other substances which cannot pass through the skin, and has but a very moderate power of dissolving the active ingredients; for this reason, though lanolin makes a good vehicle for an ointment to affect the skin, it is not always the best one when absorption of a medicinal substance is desired. *Glycelæum* is a compound of finely powdered almond meal 1 part, glycerin 2 parts, and olive oil 6 parts. It was proposed by T. B. Groves, *Chem. and Drug.*, Sept. 14, 1867, as a substitute for plasma and other fatty bodies, and has no doubt advantages, one of which is the facility with which it can be removed from the skin by a wet sponge. It has been proposed to substitute glycerin for oils and fats in the preparation of ointments, either wholly or in part; but ointments thus prepared are altogether unfit for application by inunction, as a portion of the glycerin remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter, and in some skin diseases glycerin in an ointment would be positively injurious.

The Cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the Ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance to be strictly entitled to the name of ointment which is not of such a consistence as to adapt it to application to the skin by friction or inunction. Ointments should be dispensed in glass, porcelain, or queensware pots or jars, or, if for temporary use, in tight wooden boxes. We have used a very convenient method of dispensing soft ointments by introducing them into compressible tubes. These tubes are similar to those used for holding artists' colors, and have the advantage of shielding the ointment from the oxidizing action of the air whilst allowing of the use of the desired quantity.

UNGUENTUM. U. S. Ointment.

(ŬN-GUĔN'TŬM.)

Unguentum Adipis, *U. S.* 1860; **Pommade simple**, *Fr.*; **Wachssalbe**, *G.*

"Lard, *eight hundred grammes* [or 28 ounces av., 96 grains]; Yellow Wax, *two hundred grammes* [or 7 ounces av., 24 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Yellow Wax, and gradually add to it the Lard; then stir the mixture constantly until it is cool." *U. S.*

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle, it being the basis of several official ointments.†

UNGUENTUM ACIDI BORICI. Br. Boric Acid Ointment.

(ŬN-GUĔN'TŬM ĂS'Ĭ-DĪ BŌ'RĬ-CĪ.)

"Boric Acid, in very fine powder, carefully sifted, 1 *ounce* (Imperial) or 30 grammes; Paraffin Ointment, white, 9 *ounces* (Imp.) or 270 grammes. Mix." *Br.*

* *Populinated Lard.* M. Emile Mouchon gives the following method of applying to lard the preservative influence of poplar buds and benzoin. Having prepared, by percolation, a *tincture of poplar buds* from one part of the dried buds in powder and four parts of alcohol, he adds by degrees to 1000 parts of melted lard 60 parts of the tincture, so that all the alcohol may be driven off, then strains, and agitates the mixture till it concretes on cooling. The same method is pursued with tincture of benzoin, in the same proportions; and tincture of guaiac will answer the same purpose. Lard thus prepared keeps perfectly well for a very long time. (*Journ. de Pharm.*, xxv. 458.) Mr. T. B. Groves has shown that oil of pimenta and balsam of Peru have in a powerful degree the same preservative influence on lard. (*P. J. Tr.*, Nov. 1864, p. 249.)

† *Unguentum Simplex*, *Br.*, also *U. S.* 1850. *Simple Ointment.* "Take of White Wax *two ounces* [avoirdupois]; Benzoated Lard *three ounces* [av.]; Almond Oil *three fluidounces*. Melt the Wax and Lard in the Oil on a water-bath; then remove the mixture, and stir constantly while it cools." *Br.* 1885.

UNGUENTUM ACIDI CARBOLICI. U. S., Br. Ointment of Carbolic Acid.

(ŲN-GUĔN'TŲM ĂÇ'Į-DĪ CĂR-BŎL'Į-CĪ.)

Phenol Ointment; Pommade d'Acide phénique, *Fr.;* **Phenolsalbe,** *G.*

"Carbolic Acid, *five grammes* [or 77 grains]; Ointment, *ninety-five grammes* [or 3 ounces av., 154 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them thoroughly." *U. S.*

"Phenol, ½ *ounce* (Imperial) or 15 grammes; Glycerin, 1½ *ounces* (Imp.) or 45 grammes; Paraffin Ointment, white, 10½ *ounces* (Imp.) or 315 grammes. Dissolve the Phenol in the Glycerin; add the Paraffin Ointment; mix." *Br.*

The quantity of carbolic acid in this ointment has been decreased from 10 per cent. in the U. S. P. 1880 to 5 per cent. in the 1890 revision. This is an improvement, for it is a very strong ointment, which for most purposes still requires dilution.

UNGUENTUM ACIDI SALICYLICI. Br. Salicylic Acid Ointment.

(ŲN-GUĔN'TŲM ĂÇ'Į-DĪ SĂL-Į-CŸL'Į-CĪ.)

"Salicylic Acid, in powder, 10 *grains* or 0·5 gramme; Paraffin Ointment, white, 490 *grains* or 24·5 grammes. Mix." *Br.*

UNGUENTUM ACIDI TANNICI. U. S. Ointment of Tannic Acid.

(ŲN-GUĔN'TŲM ĂÇ'Į-DĪ TĂN'NĮ-CĪ.)

Pommade d'Acide tannique, *Fr.;* **Tanninsalbe,** *G.*

"Tannic Acid, in fine powder, *twenty grammes* [or 309 grains]; Benzoinated Lard, *eighty grammes* [or 2 ounces av., 360 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Tannic Acid with the Benzoinated Lard, gradually added, until they are thoroughly mixed, avoiding the use of iron utensils." *U. S.*

Ointment of Tannic Acid was doubled in strength at the U. S. P. 1890 revision. It is an excellent application in many cases of *piles* and *prolapsus ani*, also for *flabby ulcers*.

UNGUENTUM ACONITINÆ. Br. Aconitine Ointment.

(ŲN-GUĔN'TŲM ĄC-ŎN-Į-TĪ'NÆ.)

Pommade d'Aconitine, *Fr.;* **Aconitinsalbe,** *G.*

"Aconitine, 10 *grains* or 0·5 gramme; Oleic Acid, 80 *grains* or 4 grammes; Lard, 410 *grains* or 20·5 grammes. Rub the Aconitine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

For the uses of this preparation the reader is referred to the articles on *Aconitum* and *Aconitina*. Care must be taken not to apply it to an abraded or ulcerated surface, lest it produce serious constitutional effects.

UNGUENTUM AQUÆ ROSÆ. U. S., Br. Ointment of Rose Water.

[Cold Cream.]

(ŲN-GUĔN'TŲM Ā'QUÆ RŌ'ŞÆ.)

Rose Water Ointment; Unguentum Leniens, *P. G.;* **Cérat cosmétique, Crême froide,** *Fr.*

"Spermaceti, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; White Wax, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Expressed Oil of Almond, *six hundred cubic centimeters* [or 20 fluidounces, 138 minims]; Stronger Rose Water, *one hundred and ninety cubic centimeters* [or six fluidounces, 204 minims]; Sodium Borate, in fine powder, *five grammes* [or 77 grains]. Reduce the Spermaceti and the White Wax to fine shavings, and melt them at a moderate heat. Then add the expressed Oil of Almond, pour the mixture into a warmed, shallow Wedgwood mortar, carefully add, without stirring, the whole of the Stronger Rose Water in which the Sodium Borate had previously been dissolved, and stir rapidly and continuously, until the mixture becomes uniformly soft and creamy." *U. S.*

"Rose Water, undiluted, 7 *fl. ounces* (Imperial measure) or 210 cubic centimetres; White Beeswax, 1½ *ounces* (Imp.) or 45 grammes; Spermaceti, 1½ *ounces* (Imp.) or 45 grammes; Almond Oil, 9 *ounces* (Imp.) or 270 grammes; Oil of Rose, 8 *minims* or 0·5 cubic centimetre. Melt together the White Beeswax, Spermaceti, and Almond Oil; pour the mixture into a warmed mortar and add the Rose Water gradually with constant trituration; add the Oil of Rose; continue the trituration until cold." *Br.*

In the U. S. P. 1890 process the proportion of rose water has been greatly reduced,—*i.e.*, from 30 to 20 per cent.: this will make a more stable preparation, but in our opinion the usefulness of the ointment has been curtailed by the reduction, its soft consistence being one of its most valuable characteristics. Sodium borate has been added to increase its whiteness: its presence may, however, prove objectionable when the ointment is used as a basis in prescriptions, by reacting with some of the ingredients ordered by the physician.

This preparation is a white, very soft, and elegant ointment, deriving a grateful odor from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. We have found it an improvement to add oil of rose in the proportion of one drop to eight ounces, and to use an instrument known as the "Dover egg-beater" for giving it the desired creamy appearance. It is a pleasant, cooling application to irritated and excoriated surfaces, and may be used with great advantage for chapped lips and hands, so frequent in cold weather. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Mr. Joseph Laidley has proposed the substitution for the rose water of oil of rose and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*A. J. P.*, xii. 119.) For some purposes the substitution is useful; but the official preparation is preferable for *chapped hands*, as the glycerin frequently leaves an unpleasant sensation of stickiness on the skin.

UNGUENTUM ATROPINÆ. Br. Atropine Ointment.

(ŬN-GWĔN'TŬM ĂT-RŌ-PĪ'NÆ.)

Pommade d'Atropine, *Fr.*; Atropinsalbe, *G.*

"Atropine, 10 *grains* or 0·5 gramme; Oleic Acid, 40 *grains* or 2 grammes; Lard, 450 *grains* or 22·5 grammes. Rub the Atropine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

For the uses of this ointment, see *Belladonna* and *Atropina*. Caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces, and that it be not applied too freely to sound skin.

UNGUENTUM BELLADONNÆ. U. S., Br. Belladonna Ointment.

(ŬN-GWĔN'TŬM BĔL-LĂ-DŎN'NÆ.)

Pommade de Belladone, *Fr.*; Tollkirschensalbe, *G.*

"Alcoholic Extract of Belladonna Leaves, *ten grammes* [or 154 grains]; Diluted Alcohol, *five grammes* [or 77 grains]; Benzoinated Lard, *eighty-five grammes* [or 3 ounces av.], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Extract with the Diluted Alcohol until it is uniformly soft, then gradually add the Lard, and mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 2 *fl. ounces* (Imperial measure) or 40 cubic centimetres; Benzoated Lard, 2¼ *ounces* (Imp.) or 45 grammes. Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced to a *quarter of an ounce* (Imp.) or five grammes; add the Benzoated Lard; mix. 100 parts of this Ointment should contain 0·6 part of the alkaloids of Belladonna Root." *Br.*

This is a convenient form for the external application of extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence; and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. The use of diluted alcohol, as now officially directed, is still better.

UNGUENTUM CANTHARIDIS. Br. Cantharides Ointment.

(ŬN-GWĔN'TŬM CĂN-THĂR'Ĭ-DĬS.)

Unguentum Cantharidum, *P. G.*; Unguentum Irritans, Unguentum ad Fonticulos; Onguent de Cantharides, *Fr.*; Spanischfliegensalbe, *G.*

"Cantharides, bruised, 1 *ounce* (Imperial) or 30 grammes; Benzoated Lard, 10 *ounces* (Imp.) or 300 grammes. Melt the Benzoated Lard, add the Cantharides, and digest at a temperature of about 120° F. (48·9° C.) for twelve hours. Strain through calico and press the residue gently; stir until cold." *Br.*

The British process is a better one than that of the U. S. Pharmacopœia of 1870.* Olive

* "Take of Cantharides Cerate *one hundred and twenty grains*; Resin Cerate *three hundred and sixty grains*. Mix them thoroughly." *U. S.* 1870.

oil is a good solvent of cantharidin. By its use the active matter of the flies is more uniformly diffused through the ointment than when they are directly incorporated in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces without producing undue irritation. It has been said that the virtues of the flies are impaired by boiling; but the contrary has been proved to be the case, the cantharidin being neither altered nor volatilized at 100° C. (212° F.) (See *Cantharis.*) It should be recollected that this ointment is intended as a dressing for blisters, not to produce vesication. The Committee of Revision wisely omitted the preparation from the U. S. P. 1880, as it was frequently prescribed under the impression that it was equal in strength to the cerate, in fact, identical with it, and disappointment resulted. Such a preparation should be left to extemporaneous prescription. *Dupuytren's ointment*, employed as a local application to *prevent the loss of hair*, was made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard.

UNGUENTUM CAPSICI. Br. Capsicum Ointment.

(ŲN-GUĔN'TUM CĂP'SĮ-CĪ.)

"Capsicum Fruit, bruised, 120 *grains* or 12 grammes; Spermaceti, 60 *grains* or 6 grammes; Olive Oil, 1 *ounce* (Imperial) or 44 grammes. Digest on a water-bath for one hour, occasionally stirring; strain; set aside to cool, without stirring." *Br.*

UNGUENTUM CETACEI. Br. Spermaceti Ointment.

(ŲN-GUĔN'TUM CĘ-TĀ'CĘ-Ī.)

Onguent blanc, *Fr.;* Walrathsalbe, *G.*

"Spermaceti, 20 *ounces* (Imperial) or 200 grammes; White Beeswax, 8 *ounces* (Imp.) or 80 grammes; Almond Oil, 72 *ounces* (Imp.) or 720 grammes; Benzoin, in coarse powder, 2 *ounces* (Imp.) or 20 grammes. Melt together the Spermaceti, Beeswax, and Almond Oil; add the Benzoin, and, frequently stirring the mixture, continue the application of heat for two hours; remove from the source of heat; strain; and stir the Ointment constantly until cold." *Br.*

This ointment is employed as a mild dressing for *blisters*, *wounds*, and *excoriated surfaces*. It should be made in small quantities at a time, as it is apt to become rancid when long kept.

UNGUENTUM CHRYSAROBINI. U. S., Br. Chrysarobin Ointment.

(ŲN-GUĔN'TUM ØHRĬS-Ą-RŌ-BĪ'NĪ.)

Pommade de Poudre de Goa, *Fr.;* Goapulversalbe, *G.*

"Chrysarobin, *five grammes* [or 77 grains]; Benzoinated Lard, *ninety-five grammes* [or 3 ounces av., 154 grains]. To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Chrysarobin with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Chrysarobin, 20 *grains* or 2 grammes; Benzoated Lard, 480 *grains* or 48 grammes. Triturate the Chrysarobin gradually with the Benzoated Lard, previously melted by heat; continue the heat until the Chrysarobin is dissolved; stir until cold." *Br.*

This ointment was reduced one-half in strength at the U. S. P. 1890 revision, which is an improvement: it is now very nearly identical with the British ointment. It was formerly used in *psoriasis*, *ringworm*, and other *diseases of the skin*, but its use has been to a great extent abandoned, on account of the permanent stain that it leaves upon the linen.* It is preferably made by dissolving the chrysarobin in a little hot benzol, mixing this rapidly with a portion of the melted lard, and subsequently stirring before adding the rest of the lard.

UNGUENTUM COCAINÆ. Br. Cocaine Ointment.

(ŲN-GUĔN'TUM CŌ-CĄ-Ī'NÆ.)

"Cocaine, 20 *grains* or 1 gramme; Oleic Acid, 80 *grains* or 4 grammes; Lard, 400 *grains* or 20 grammes. Rub the Cocaine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

* The *ointment of pyrogallic acid*, of the strength of from ten to forty grains to the ounce, has been used to some extent as a substitute for chrysarobin ointment. It is slower in its action than the ointment of chrysarobin, and also stains the hair, skin, etc. It is said when used too freely to cause constitutional disturbance, with fever, greenish urine, etc.

UNGUENTUM CONII. Br. Conium Ointment.

(ŲN-GUĔN'TŲM CŌ-NĪ'Ī.)

"Juice of Conium, 2 *fl. ounces* (Imperial measure) or 88 cubic centimetres; Hydrous Wool Fat, ¾ *ounce* (Imp.) or 33 grammes. Evaporate the Juice of Conium on a water-bath to one eighth of its volume, at a temperature not exceeding 140° F. (60° C.); add the Hydrous Wool Fat; mix by trituration." *Br.*

It may be applied locally to cancerous or other painful ulcers, but has little therapeutic value.

UNGUENTUM CREOSOTI. Br. Creosote Ointment.

(ŲN-GUĔN'TŲM CRĒ-Ō-SŌ'TĪ.)

Pommade de Créosote, *Fr.;* Kreosotsalbe, *G.*

"Creosote, 1 *ounce* (Imperial) or 30 grammes; Hard Paraffin, 4 *ounces* (Imp.) or 120 grammes; Soft Paraffin, white, 5 *ounces* (Imp.) or 150 grammes. Melt the Hard and Soft Paraffins together; add the Creosote; stir until cold." *Br.*

The British ointment is more than twice as strong as that official in the U. S. P. 1870, which was made by mixing half a fluidrachm of creosote with a troyounce of lard. For the use of this ointment, see *Creosotum.* It may sometimes be advantageously diluted with lard when found to irritate.

UNGUENTUM DIACHYLON. U. S. Diachylon Ointment.

(ŲN-GUĔN'TŲM DĪ-ĂK'Ĭ-LŎN.)

Pommade de Diachylon, *Fr.;* Diachylonsalbe, *G.*

"Lead Plaster, *five hundred grammes* [or 17 ounces av., 278 grains]; Olive Oil, *four hundred and ninety grammes* [or 17 ounces av., 125 grains]; Oil of Lavender Flowers, *ten cubic centimeters* [or 162 minims], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt together the Lead Plaster and the Olive Oil, on a water-bath; then, having allowed the mixture to become partly cool, add the Oil of Lavender Flowers, and stir constantly, until the Ointment is cold." *U. S.* The proportion of lead plaster has been reduced in the U. S. 1890 formula ten per cent.: this is an improvement.

This ointment has been largely used by dermatologists in *eczema* and other *skin diseases.* It is frequently called "*Unguentum Diachylon Hebræ,*" on account of its extensive use by the late Prof. Hebra, of Vienna. Vulpius states that the ointment used at Hebra's clinic, made according to the following formula, is very superior and will keep for weeks. Twenty parts of litharge are heated with sufficient water and eighty parts of olive oil until the reaction is completed, when one part of oil of lavender is added to the strained and cooling mass.

Our experience with the ointment made by the latter formula is that the tendency to rancidity constitutes its greatest objection, and in warm weather it is impossible to keep it longer than a few days. If even slightly rancid, it is unfit for use in most cases. A. Deringer (*Pharm. Zeitschr. für Russland,* 1880, p. 103; *A. J. P.,* Sept. 1880) recommends the following modification. Dissolve 200 grammes of lead acetate in 1 liter of distilled water and 300 grammes of white Marseilles soap in 1½ liters of distilled warm water, filter both solutions, mix, wash the resulting precipitate frequently with distilled water, and, after removing the moisture from it as much as possible, melt 1 part of it together with 1½ parts of the best olive oil on a steam evaporating apparatus, and triturate into a white, smooth ointment in a mortar, which then possesses all the excellent mild and healing properties of Hebra's ointment.

M. Eisner's modification, approved by Prof. L. A. Duhring, is as follows. One part of freshly precipitated (from lead acetate) pure white lead hydroxide is rubbed with two parts of water, and mixed well with six parts of the best Lucca olive oil. It should be stirred for about two hours over a hot-water bath near the boiling point, and cooled with constant stirring until the proper consistence is obtained. While cooling, a drachm of oil of lavender is to be added to each half-pound of ointment. (*Med. Times,* May 7, 1881.)

UNGUENTUM EUCALYPTI. Br. Eucalyptus Ointment.

(ŲN-GUĔN'TŲM EŪ-CĄ-LĬP'TĪ.)

"Oil of Eucalyptus, 1 *ounce* (Imperial) or 30 grammes; Hard Paraffin, 4 *ounces* (Imp.) or 120 grammes; Soft Paraffin, white, 5 *ounces* (Imp.) or 150 grammes. Melt the Hard and Soft Paraffins together; add the Oil of Eucalyptus; stir until cold." *Br.*

This ointment is used as a stimulant to indolent *ulcers* and in *skin diseases.*

UNGUENTUM GALLÆ. U. S., Br. Nutgall Ointment.

(ŲN-GUĔN'TŲM GĂL'LÆ.)

Gall Ointment; Ointment of Galls; Pommade de Noix de Galle, *Fr.*; Galläpfelsalbe, *G.*

"Nutgall, in No. 80 powder, *twenty grammes* [or 309 grains]; Benzoinated Lard, *eighty grammes* [or 2 ounces av., 360 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Nutgall with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Galls, in very fine powder, 1 *ounce* (Imperial) or 30 grammes; Benzoated Lard, 4 *ounces* (Imp.) or 120 grammes. Mix by trituration." *Br.*

Care should be taken to have the nutgall in very fine powder and thoroughly sifted. This ointment is used chiefly in *piles* and *prolapsus ani*, and in *flabby* or *indolent ulcers*.

UNGUENTUM GALLÆ CUM OPIO. Br. Gall and Opium Ointment.

(ŲN-GUĔN'TŲM GĂL'LÆ CŬM Ō'PĮ-Ō.)

"Gall Ointment, 925 *grains* or 92·5 grammes; Opium, in very fine powder, 75 *grains* or 7·5 grammes. Mix by trituration. 100 parts of this Ointment contain 7½ parts of Opium." *Br.*

This combination of galls and opium is sometimes employed for *hemorrhoids*. From half a drachm to a drachm of camphor is sometimes added.

UNGUENTUM GLYCERINI PLUMBI SUBACETATIS. Br. Lead Subacetate Ointment.

(ŲN-GUĔN'TŲM GLĬŶ-Ę-RĪ'NĪ PLŬM'BĪ SŬB-ĂÇ-Ę-TĀ'TĬS.)

"Glycerin of Lead Subacetate, 1 *ounce* (Imperial) or 30 grammes; Paraffin Ointment, white, 5 *ounces* (Imp.) or 150 grammes. Mix." *Br.*

This ointment has therapeutic properties similar to those of Goulard's cerate.

UNGUENTUM HAMAMELIDIS. Br. Hamamelis Ointment.

(ŲN-GUĔN'TŲM HĂM-Ą-MĔL'Į-DĬS.)

"Liquid Extract of Hamamelis, ½ *fl. ounce* (Imperial measure) or 10 cubic centimetres; Hydrous Wool Fat, 2½ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

This was one of the "Additions" to the British Pharmacopœia, 1885. It is, in our opinion, of doubtful utility, but may be rubbed in over *sprains*.

UNGUENTUM HYDRARGYRI. U. S., Br. Mercurial Ointment. [Blue Ointment.]

(ŲN-GUĔN'TŲM HŸ-DRĂR'ĢŲ-RĪ.)

Mercury Ointment; Unguentum Hydrargyri Cinereum, *P. G.*; Unguentum Mercuriale, s. Neapolitanicum; Pommade (Onguent) mercurielle, Pommade napolitaine, *Fr.*; Graue Quecksilbersalbe, *G.*

"Mercury, *five hundred grammes* [or 17 ounces av., 278 grains]; Lard, *two hundred and fifty grammes* [or 8 ounces av., 358 grains]; Suet, *two hundred and thirty grammes* [or 8 ounces av., 49 grains]; Oleate of Mercury *twenty grammes* [or 309 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the Oleate of Mercury with the Mercury, gradually added, in a mortar, until globules of the metal are no longer visible. Then add the Lard and Suet, previously melted together and partially cooled, and continue the trituration until globules of Mercury are no longer visible under a lens magnifying ten diameters." *U. S.*

"Mercury, 1 *pound* (Imperial) or 160 grammes; Lard, 1 *pound* (Imp.) or 160 grammes; Prepared Suet, 1 *ounce* (Imp.) or 10 grammes. Triturate until metallic globules cease to be visible." *Br.*

The Pharmacopœias unite at present in recognizing but one mercurial ointment, which contains practically equal weights of mercury and fatty matter. When the physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purpose.

The U. S. official formula is particularly adapted to the extemporaneous preparation of this ointment, it having been shown that the extinguishment of the mercury is facilitated by the use of oleate of mercury, whilst its presence undoubtedly adds to the efficiency of the ointment. Oleic acid was suggested by Leo Eliel (see *Indiana Pharmacist*, 1888) in the proportion of 1 per cent. for the extinction of the mercury. The addition of 4 per cent. of

compound tincture of benzoin aids in the preservation of the ointment. The trituration should not be accompanied with pressure, a light, rapid motion of the pestle being most effective. In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is usually performed upon the large scale in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globes under a magnifying glass of ten diameters. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed, but are inadmissible,—the former because it renders the ointment too irritating, the latter because it forms with the mercury an active sulphide. Their presence in the ointment may be detected by the peculiar odor which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker color. Rancidity in the lard facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine, only to a greater degree. M. Guibourt recommends the addition of one-sixteenth of old mercurial ointment.* M. Simonin proposes the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal, but probably renders the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment was proposed by M. Chevallier. A pound of mercury, and half a pound of fresh lard, previously melted, are introduced into a stone or glass bottle, shaken till the mixture acquires the consistence of very thick syrup, then poured into a mortar, and incorporated, by constant stirring, with an additional half-pound of lard. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. Dr. E. R. Squibb prepares this ointment by succussion in an apparatus which agitates the mixture of fats and mercury until the metal is extinguished. When prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the official use of suet; and even a larger proportion might be employed, during the summer season.† Dr. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day and allow the ointment in the mean time to be exposed to the air. But so much time and labor are required in this process that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 37·7° C. (100° F.), are triturated with the metal by means of two iron balls which are driven rapidly round in a circular trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours. In buying from the manufacturer, great care should be exercised by the pharmacist, as much of the commercial ointment contains less than the official percentage of mercury. Indeed, it is sometimes found in the market without a trace of mercury, having been made by mixing up lampblack with rancid lard and suet until the proper tint is obtained. A method of preparing mercurial ointment proposed by Orosi is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of stannous chloride, with the addition of hydrochloric acid, and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place. For an account of many expedients that have been proposed to facilitate the extinguishment of the metal, see a paper by Dieterich (*A. J. P.*, 1880).

* It appears that Mr. J. Higginbottom made known, so long ago as the year 1814, this mode of extinguishing mercury. He recommends that equal weights of the old ointment and of mercury should be rubbed together, till the globules quite disappear, and the requisite proportion of lard then added. It is not necessary that the mercurial ointment should be rancid. (*P. J. Tr.*, xvi. 215.) For a process recommended by Mr. J. M. Maisch, of which the peculiarity is the use of mercury passed through chamois leather, so as to be sprinkled in minute division over the fat, see *A. J. P.* (xxviii. 107); and for another by Mr. E. H. Hance, in which melted spermaceti is employed as the extinguishing material, and which is said to answer well for small quantities, see the same journal (xxix. 15). M. E. Mouchon uses wax or stearin to facilitate extinguishment, and recommends benzoinated lard as the vehicle. (*Journ. de Chim. Méd.*, Nov. 1856, p. 652.) Geo. Boyle uses a portion of old mercurial ointment and ether. (*A. J. P.*, xlvi. 561.) M. Melseur affirms that the addition of glycerin very materially hastens the process. (*P. J. Tr.*, 1871, p. 339.)

† *Oleum Cinereum.* Oleum cinereum is a mercurial preparation used by Dr. E. Lang in syphilitic complaints. It is prepared by triturating, in a cool place, lard, oil, and mercury until the latter becomes uniformly suspended, the finished preparation to contain 20 per cent. of the metal. It is used as a local dressing, also as an injection to enlarged glands, 0·01 to 0·02 C.c. being given once a week or in a fortnight. For use it is melted by the warmth of the hand. (*Wien. Med. Wochenschr.*, 1886.)

Mercurial ointment has when freshly prepared a bluish color, which becomes darker with age. It has been thought to contain the mercury in the state of mercurous oxide; but most of the metal can be separated by methods not calculated to reduce the oxide, and it is now generally admitted that by far the greater part of it exists in a state of minute division and not of chemical combination. It has been shown, however, that the metal is slightly oxidized; and the change of color which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by hydrogen sulphide, and yields a trace of mercurial oxide to acetic acid. Dr. Christison states that he has examined various samples of the ointment, and never failed to detect mercurial oxides; and he has inferred from his observations that the oxide amounts to rather more than 1 per cent. (*Christison's Dispensatory.*) But the proportion is variable, according to the age and mode of preparation of the ointment. It scarcely admits of a doubt that the mercurial oxide formed enters into chemical combination with the lard or one of its fatty acids. Mr. Donovan advanced the idea that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black mercurial oxide has not the same effect, however, because there is no chemical union between the ingredients. But upon exposing such a mixture to a temperature of 176·6° C. (350° F.), and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the official directions, as being more manageable and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low, as the former might decompose the oxide, and the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat. From experiments by a committee of the College of Pharmacy of New York, it appears that mercurial ointment in time becomes unequal in strength in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated, so as to restore an equable strength, before being dispensed. (*A. J. P.*, xvi. 2.)

Medical Uses. Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections, as in the case of *venereal buboes*, and of *chronic glandular swellings*, upon which it may be made to operate directly by being applied in the course of the absorbents passing through the enlarged glands. The proper quantity to be employed at one time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected. (See *Oleatum Hydrargyri*, page 911.)

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption, which interferes with its continued application. Camphor is sometimes added, in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence when too firm from a large proportion of suet. Mercurial ointment has been employed, with some success, to prevent the maturation of the *small-pox pustule*, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in *erysipelas* and in *chilblains*. Potassium iodide rubbed with mercurial ointment is said to promote the separation of the mercury in the form of globules (*Journ. de Pharm.*, 3e sér., x. 356); but the effect will not take place if the iodide have been thoroughly dried and well powdered and the ointment be added to it in small portions at a time. (*Ibid.*, x. 421.) The ointment, diluted with twice or three times its weight of lard, is sometimes applied to *ulcers*, and to certain *cutaneous eruptions*.

UNGUENTUM HYDRARGYRI AMMONIATI. U. S., Br. Ammoniated Mercury Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'ĢĮ-RĪ ĄM-MŌ-NĮ-Ā'TĪ.)

White Precipitate Ointment; Unguentum Præcipitati Albi; Ointment of White Precipitate; Unguentum Hydrargyri Præcipitati Albi, *P. G.;* Pommade de Précipité blanc, *Fr.;* Weisse Quecksilbersalbe, *G.*

"Ammoniated Mercury, in very fine powder, *ten grammes* [or 154 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Ammoniated Mercury with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Ammoniated Mercury, 1 *ounce* (Imperial) or 30 grammes; Paraffin Ointment, white, 9 ounces (Imp.) or 270 grammes; Mix." *Br.*

Used chiefly in cutaneous eruptions, such as *psora*, *porrigo*, and *herpes*.

UNGUENTUM HYDRARGYRI COMPOSITUM. Br. Compound Mercury Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'ĢĮ-RĪ CŌM-PŎŞ'Į-TŬM.)

Pommade mercurielle composée, *Fr.;* Kampfer Quecksilbersalbe, *G.*

"Mercury Ointment, 10 *ounces* (Imperial) or 150 grammes; Yellow Beeswax, 6 *ounces* (Imp.) or 90 grammes; Olive Oil, 6 *ounces* (Imp.) or 90 grammes; Camphor, in flowers, 3 *ounces* (Imp.) or 45 grammes. Mix the Beeswax, Olive Oil, and Mercury Ointment with the aid of heat; add the Camphor; triturate until cold." *Br.*

The addition of camphor to mercurial ointment tends to soften it, and is thought by some to promote the absorption of the mercury. (See *Unguentum Hydrargyri.*)

UNGUENTUM HYDRARGYRI IODIDI RUBRI. Br. Mercuric Iodide Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'ĢĮ-RĪ Ī-ŎD'Į-DĪ RŬ'BRĪ.)

Ointment of Red Iodide of Mercury; Pommade de Deutoiodure de Mercure, *Fr.;* Jodquecksilbersalbe, *G.*

"Mercuric Iodide, in fine powder, 20 *grains* or 2 grammes; Benzoated Lard, 480 *grains* or 48 grammes. Mix." *Br.*

This ointment is employed as a dressing to indolent *scrofulous* and *syphilitic ulcers*.

UNGUENTUM HYDRARGYRI NITRATIS. U. S., Br. Ointment of Mercuric Nitrate. [Citrine Ointment.]

(ŲN-GUĔN'TUM HĬ-DRĂR'ĢĮ-RĪ NĪ-TRĀ'TĬS.)

Unguentum Citrinum; Unguentum Hydrargyri Citrinum; Pommade de Nitrate de Mercure, *Fr.;* Gelbe Quecksilbersalbe, *G.*

"Mercury, *seventy grammes* [or 2 ounces av., 205 grains]; Nitric Acid, *one hundred and seventy-five grammes* [or 6 ounces av., 76 grains]; Lard Oil, *seven hundred and sixty grammes* [or 26 ounces av., 354 grains]. Heat the Lard Oil, in a glass or porcelain vessel, to a temperature of 100° C. (212° F.); then withdraw the heat, gradually add *seventy grammes* [or 2 ounces av., 208 grains] of Nitric Acid, and, when the reaction moderates, reapply the heat, until effervescence ceases. Then allow the mixture to cool to about 40° C. (104° F.). Having dissolved the Mercury in the remainder of the Nitric Acid with the aid of sufficient heat to prevent the solution from crystallizing, add this solution to the mixture. When the mass has become entirely cold, mix it thoroughly by trituration, avoiding the use of a metallic spatula." *U. S.*

"Mercury, 1 *ounce* (Imperial) or 100 grammes; Nitric Acid, 3 *fl. ounces* (Imp. meas.) or 300 cubic centimetres; Lard, 4 *ounces* (Imp.) or 400 grammes; Olive Oil, 7 *ounces* (Imp.) or 700 grammes. Dissolve the Mercury in the Nitric Acid without the aid of heat, agitating gently from time to time. Heat the Lard and Olive Oil together on a sand-bath, so that the mixture when transferred to a heated earthenware jar, capable of holding ten times the quantity, shall be at a temperature of 290° F. (143·3° C.). Add the cold mercurial solution very gradually, stirring constantly to promote disengagement of the fumes. After frothing has ceased, the mixture, which should have a temperature of not less than 200° F. (93·3° C.), must be kept stirred until it is cold. The resulting Ointment should be firm in consistence and have a pale lemon color." *Br.*

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. In the British process and that of the U. S. P. 1870 the mercury, in the first step of the process, is converted into a mixture of mercuric and mercurous nitrate by the addition of nitric acid in excess, with the loss of some of the free nitric acid through deoxidation. When the acid mercurial solution is added to the fatty matter, a reaction takes place, which results in the fat being oxidized at the expense of the free nitric acid, nitrogen dioxide and nitrogen tetroxide being at the same time liberated, and the olein of the fat is converted into elaidin, which change is recognized by the beautiful orange color of the fat. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty-greenish and mottled color, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and many different modifications of the process were proposed in order to obviate them. The U. S. process of 1850 was based upon the fact that the olive oil of the former British process is hardened by nitrous acid or mercuric nitrate, while the same effect is not produced upon neat's-foot oil. As at first published, the process was defective in the direction to add the mercurial solution to the mixed oleaginous fluid when it begins to stiffen on cooling. When this direction was complied with, at least with the acid of the ordinary strength, the preparation had a brown color and a semi-liquid consistence; but with some modifications, such as were introduced into the revised formula of the Pharmacopœia of 1860, the process yielded an excellent ointment, which, though it sometimes assumed a greenish color on exposure, retained permanently a soft unctuous consistence. We have had specimens of the ointment in our possession for several years which have retained a uniform yellowish color and a perfectly good unctuous consistence. R. Rother, however, affirmed that the fault was not in the components, but in the processes of the official formula of 1870 (*A. J. P.*, xlii. 420), especially in the use of too high a heat;* and these views have been confirmed by ample experience. The present official process is, as will be seen, based on Rother's formula, the principal modification being the substitution of lard oil, which obviates a tendency of the ointment to become too hard and of a granular consistence. The value of Rother's process lies principally in the fact that the olein of the oil is first converted into elaidin by the addition of nitric acid alone and the application of heat, and when the reaction has ceased and the basis of citrine ointment, as it might be called, is prepared, and nearly cold, the mercurial solution is added. In this way decomposition of the mercuric nitrate is avoided, as it is not subjected to heat, and the result is an ointment which will retain its color and consistence a long time. The drying vegetable oils appear, like olive oil, to be converted by nitrous acid or mercuric nitrate into elaidin; and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Dr. Fessenden, of North Carolina, states, in an inaugural essay, that he substituted linseed oil for the neat's-foot oil of the U. S. process, and succeeded in obtaining a perfectly good and durable ointment. M. Falières has found the oil of the ground-nut (*Arachis hypogæa*) to answer very well. (*P. J. Tr.*, 1873, p. 1031.) Purified cotton-seed oil makes an excellent base. Washed butter is frequently used as the fat.

In the British process, when the fatty matter and the mercurial solution are mixed, care must be taken that the heat applied be not too great. Gas is extricated at 82·2° C. (180° F.), and at 100° C. (212° F.) escapes so abundantly that the mixture boils over unless the vessel is very large. (*Alsop.*) Besides, if the heat be too great, a portion of the mercury will be reduced, and the color of the ointment impaired. When large quantities of materials are operated

* R. Rother's formula is as follows. "Take of Mercury 1½ troyounces; Nitric Acid, sp. gr. 1·42, 3½ troyounces; Lard, pure, 16½ troyounces. Dissolve the Mercury in 900 grains of the Nitric Acid, with the aid of heat, and keep the solution gently warm to prevent crystallization before it is used. Melt the Lard in a suitable vessel, with a moderate heat; then add the remainder of the Nitric Acid, and continue the heat, *without* stirring the mixture, as long as moderate effervescence continues; but if this becomes too violent, remove the mixture from the fire, and replace it only when the action slackens too much. Finally, when effervescence ceases, and the liquid only boils even under an increased heat, remove the mixture from the fire altogether; and when it begins to stiffen, add the mercurial solution and mix thoroughly." (*A. J. P.*, xlii. 420.) (For a formula in which neat's-foot oil is used, asserted by Mr. Thos. J. Covell to be superior to the official, and for a bibliography of the subject, see *A. J. P.*, xlii. 211.)

upon, the reaction which occurs produces of itself a sufficient heat; but in ordinary cases the temperature should be kept at about 87·7° C. (190° F.) by means of a water-bath, and if it exceed 96·1° C. (205° F.) should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel; and a glass rod or a wooden spatula should be employed for stirring the mixture. Under no circumstances should an iron or steel spatula or stirrer be used in its preparation, because of the discoloration due to the action of the acid upon the iron.

Medical Uses. This ointment is much and very advantageously employed, as a stimulant and alterative application, in *porrigo* or *tinea capitis*, *impetigo larvalis* or *crusta lactea*, *psoriasis* and *pityriasis*, certain forms of *chronic eczema*, *psorophthalmia* and *inflammation of the eye and eyelids* connected with porrigo of the face or scalp, and various other *ulcerative* and *eruptive affections*. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. An ointment prepared with lard and nitric acid, called *Alyon's ointment*, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias was of this character.

UNGUENTUM HYDRARGYRI NITRATIS DILUTUM. Br. Diluted Mercuric Nitrate Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'GĮ-RĪ NĪ-TRĀ'TĬS DĪ-LŪ'TŬM.)

"Mercuric Nitrate Ointment, 1 *ounce* (Imperial) or 25 grammes; Soft Paraffin, yellow, 4 *ounces* (Imp.) or 100 grammes. Mix." *Br.*

UNGUENTUM HYDRARGYRI OLEATIS. Br. Mercuric Oleate Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'GĮ-RĪ Ō-LĒ-Ā'TĬS.)

"Mercuric Oleate, 1 *ounce* (Imperial) or 20 grammes; Benzoated Lard, 3 *ounces* (Imp.) or 60 grammes. Mix." *Br.*

UNGUENTUM HYDRARGYRI OXIDI FLAVI. U.S., Br. Ointment of Yellow Mercuric Oxide.

(ŲN-GUĔN'TUM HĬ-DRĂR'GĮ-RĪ ŎX'Į-DĪ FLĀ'VĪ.)

Yellow Mercuric Oxide Ointment; Pommade d'Oxyde jaune de Mercure, *Fr.;* Gelbe Quecksilberoxydsalbe, *G.*

"Yellow Mercuric Oxide, in very fine powder, *ten grammes* [or 154 grains]; Ointment, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Yellow Mercuric Oxide with the Ointment, gradually added, until they are thoroughly mixed." *U. S.*

"Yellow Mercuric Oxide, in very fine powder, 10 *grains* or 0·5 gramme; Soft Paraffin, yellow, 490 *grains* or 24·5 grammes. Mix." *Br.*

The unctuous vehicle of this ointment, without being so liquid as to allow the powder to subside, must yet melt at the heat of the body, and thus, when introduced into the eye, spread equably over the surface. It should, moreover, be as far as possible chemically indifferent to the oxide, and, while perfectly bland in its proper state, should not be liable to become irritating by rancidity. Simple ointment has been adopted by the revisers of the Pharmacopœia; but petrolatum, or a mixture of butter of cacao and almond oil, or of spermaceti, wax, and almond oil, without the rose water, would be more elegant. (*P. J. Tr.*, 2d ser., vii. 324.) For medical properties, see *Unguentum Hydrargyri Oxidi Rubri.*

UNGUENTUM HYDRARGYRI OXIDI RUBRI. U.S., Br. Ointment of Red Mercuric Oxide.

(ŲN-GUĔN'TUM HĬ-DRĂR'GĮ-RĪ ŎX'Į-DĪ RŪ'BRĪ.)

Red Precipitate Ointment; Unguentum Hydrargyri Rubrum, *P.G.;* Unguentum Præcipitatum Rubrum; Pommade de Précipité rouge, Baume ophthalmique rouge, *Fr.;* Rothe Quecksilbersalbe, *G.*

"Red Mercuric Oxide, in very fine powder, *ten grammes* [or 154 grains]; Castor Oil, *five grammes* [or 77 grains]; Ointment, *eighty-five grammes* [or 3 ounces av.], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Red Mercuric Oxide with the

Castor Oil, until a perfectly smooth mixture results; then gradually incorporate the Ointment, and mix thoroughly." *U. S.*

"Red Mercuric Oxide, in very fine powder, ¼ *ounce* (Imperial) or 10 grammes; Paraffin Ointment, yellow, 2¼ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

A change has been made in this ointment by the addition of five per cent. of castor oil, to facilitate the fine division of the mercuric oxide.

The red mercuric oxide here referred to is that prepared from the nitrate and usually called *red precipitate.* It is important that the oxide should be thoroughly pulverized before being mixed with the lard, as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used. When great care is taken to have the red oxide very finely pulverized, the color is more yellowish than is usual. This ointment loses its fine red color when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it in small quantities at a time. We have been informed that if the preparation be made by mixing the red oxide with poplar-bud ointment it will keep a long time without change. According to R. H. Stabler, of Alexandria, Va., an equally effectual method is to mix two drops of liquor potassæ with each ounce of the ointment when prepared (*A. J. P.*, xxiii. 123); but Mr. Julius Kalish states that this is not effectual. Mr. Emil Martin states that if a mixture of six parts of castor oil to two of wax be used as the basis of the ointment the red color will remain unchanged for years. (*A. J. P.*, xliv. 202.) Mr. Kalish substitutes oil of sweet almond for the castor oil, on account of the unpleasant odor of the latter. (*A. J. P.*, xlv. 69.) Ointment of red mercuric oxide is a highly useful stimulating ointment, much employed in *indolent and foul ulcers*, in *porrigo* of the scalp, and in *psorophthalmia* and *chronic conjunctival ophthalmia*, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea, but it is rapidly being supplanted by the ointment of yellow mercuric oxide. It may be diluted with lard if found too stimulating.

UNGUENTUM HYDRARGYRI SUBCHLORIDI. Br. Mercurous Chloride Ointment.

(ŲN-GUĔN'TUM HĬ-DRĂR'GĮ-RĪ SŬB-ȻHLŌ'RĮ-DĪ.)

Ointment of Subchloride of Mercury; Unguentum Calomelanos, *Br.* 1864; Ointment of Calomel; Pommade de Calomélas, *Fr.*; Quecksilberchlorürsalbe, *G.*

"Mercurous Chloride, ¼ *ounce* (Imperial) or 10 grammes; Benzoated Lard, 2¼ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

There is little occasion for such a preparation as this. Calomel is much inferior to the mercurial ointment for affecting the system by inunction; and as an application to ulcerated surfaces the form of cerate would be better. It may, however, be useful in certain *cutaneous eruptions.*

UNGUENTUM IODI. U. S., Br. Iodine Ointment.

(ŲN-GUĔN'TUM Ī-Ō'DĪ.)

Unguentum Iodinii, *U. S.* 1870; Pommade d'Iode, *Fr.*; Jodsalbe, *G.*

"Iodine, *four grammes* [or 62 grains]; Potassium Iodide, *one gramme* [or 15 grains]; Water, *two cubic centimeters* [or 32 minims]; Benzoinated Lard, *ninety-three grammes* [or 3 ounces av., 123 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Iodine and the Potassium Iodide, first with the Water, and then with the Benzoinated Lard, gradually added, until they are thoroughly mixed, avoiding the use of a metallic spatula. This preparation should be freshly made, when required." *U. S.**

"Iodine, 20 *grains* or 1 gramme; Potassium Iodide, 20 *grains* or 1 gramme; Glycerin, 60 *grains* or 3 grammes; Lard, 400 *grains* or 20 grammes. Triturate the Iodine, Potassium Iodide, and Glycerin, in a glass or porcelain mortar; add the Lard gradually; mix." *Br.*

The object of the potassium iodide and water is simply to bring the iodine into a state in which it may be thoroughly and equably incorporated with the lard. They have been found to answer better in practice than the alcohol formerly used. Owing to the evaporation of the water, this ointment is said at times to contain sharp crystals of iodine. The use of glycerin instead of water would obviate this. When rubbed upon the skin it imparts to it an orange color, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in *goitre*, *scrofulous swellings of the glands*, and other *chronic tumefactions*, in-

* *Unguentum Iodinii Compositum.* U. S. 1870. "Take of Iodine *fifteen grains*; Iodide of Potassium *thirty grains*; Water *thirty minims*; Lard *a troyounce.* Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard, until they are thoroughly mixed."

ternal or external, operating probably through the medium of absorption. When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. It has also been recommended in *chilblains*. The ointment should be prepared only when wanted for use; for it undergoes change if kept, losing its deep orange-brown color, and becoming pale upon its surface.

UNGUENTUM IODOFORMI. U. S., Br. Iodoform Ointment.

(ŲN-GUĔN'TUM Ī-Ǫ-DǪ-FÖR'MĪ.)

"Iodoform, in very fine powder, *ten grammes* [or 154 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Iodoform with the Benzoinated Lard, gradually added, until they are thoroughly mixed. This preparation should be freshly made, when required." *U. S.*

"Iodoform, in fine powder, ¼ *ounce* (Imperial) or 10 grammes; Paraffin Ointment, yellow, 2¼ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

It is important to have the iodoform in very fine powder, as officially directed, and, owing to the powerful odor of iodoform, it is usual to add oil of bitter almond or one of the other volatile oils, balsam of Peru, or a similar substance, to render the odor more bearable.

UNGUENTUM PARAFFINI. Br. Paraffin Ointment.

(ŲN-GUĔN'TUM PĂR-ĄF-FĪ'NĪ.)

"Hard Paraffin, 3 *ounces* (Imperial) or 90 grammes; Soft Paraffin, 7 *ounces* (Imp.) or 210 grammes. Melt together in a shallow evaporating dish; as the liquid cools triturate constantly, until, when cold, a uniform plastic ointment is produced. When Paraffin Ointment is used as the basis of white ointments, it should be prepared with the white variety of Soft Paraffin; and when used in colored ointments it should be prepared with the yellow variety of Soft Paraffin. The proportions of Hard and Soft Paraffins in Paraffin Ointment may be modified to meet the exigencies of climate and prevailing temperature." *Br.*

This ointment has been introduced in the Br. Ph. 1898 to serve as a vehicle for the exhibition of various medicaments; it has but limited powers of absorption in this respect, being inferior to oleic acid or lard.

UNGUENTUM PICIS LIQUIDÆ. U. S., Br. Tar Ointment.

(ŲN-GUĔN'TUM PĪ'CĬS LĬQ'UĮ-DÆ.)

Pommade de Goudron, *Fr.*; Theersalbe, *G.*

"Tar, *five hundred grammes* [or 17 ounces av., 279 grains]; Yellow Wax, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Lard, *three hundred and seventy-five grammes* [or 13 ounces av., 100 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt together the Yellow Wax and the Lard at a moderate heat. Then incorporate the Tar, strain the mixture through muslin, and stir the Ointment constantly until it is cool." *U. S.*

"Tar, 5 *ounces* (Imperial) or 100 grammes; Yellow Beeswax, 2 *ounces* (Imp.) or 40 grammes. Melt the Beeswax at a low temperature; add the Tar; stir the mixture until cold." *Br.*

The formula for tar ointment in the U. S. P. 1890 differs from that formerly official in the use of yellow wax and lard in place of suet. This ointment is highly useful as a stimulant application in various *scaly* and *scabby eruptions*, particularly in *psoriasis* and *lepra*, and in that form of *porrigo* usually called *tinea capitis*, or *scald-head*. In the last-mentioned affection it should be applied night and morning; and in bad cases the patient should constantly wear a cap thickly coated internally with the ointment.

UNGUENTUM PLUMBI ACETATIS. Br. Lead Acetate Ointment.

(ŲN-GUĔN'TUM PLŬM'BĪ ĂÇ-Ę-TĀ'TĬS.)

"Lead Acetate, in fine powder, 20 *grains* or 2 grammes; Paraffin Ointment, white, 480 *grains* or 48 grammes. Mix." *Br.*

An official of the Br. Pharmacopœia, used as a dressing for *inflamed and excoriated surfaces*, though inferior, we think, to the cerate of the subacetate.

UNGUENTUM PLUMBI CARBONATIS. U. S., Br. Ointment of Lead Carbonate.

(ŲN-GUĔN'TUM PLŬM'BĪ CĂR-BO-NĀ'TĪS.)

Lead Carbonate Ointment; Unguentum Cerussæ, s. Unguentum Album Simplex, *P. G.;* Pommade de Carbonate de Plomb, Onguent blanc de Rhazis, *Fr.;* Bleiweissalbe, *G.*

"Lead Carbonate, in very fine powder, *ten grammes* [or 154 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Lead Carbonate with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Lead Carbonate, in fine powder, ¼ *ounce* (Imperial) or 10 grammes; Paraffin Ointment, white, 2¼ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

This ointment is used as a dressing to *blistered or excoriated surfaces, burns,* etc.

UNGUENTUM PLUMBI IODIDI. U. S., Br. Ointment of Lead Iodide.

(ŲN-GUĔN'TUM PLŬM'BĪ Ī-ŎD'Į-DĪ.)

Lead Iodide Ointment; Pommade d'Iodure de Plomb, *Fr.;* Jodbleisalbe, *G.*

"Lead Iodide, in very fine powder, *ten grammes* [or 154 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Lead Iodide with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Lead Iodide, in fine powder, ¼ *ounce* (Imperial) or 10 grammes; Paraffin Ointment, yellow, 2¼ *ounces* (Imp.) or 90 grammes. Mix." *Br.*

For the uses of this ointment, see *Plumbi Iodidum.*

UNGUENTUM POTASSII IODIDI. U. S., Br. Ointment of Potassium Iodide.

(ŲN-GUĔN'TUM PO-TĂS'SĮ-Ī Ī-ŎD'Į-DĪ.)

Potassium Iodide Ointment; Unguentum Kalii Iodati, *P. G.;* Pommade iodurée, *Fr.;* Jodkaliumsalbe, *G.*

"Potassium Iodide, *twelve grammes* [or 185 grains]; Sodium Hyposulphite, *one gramme* [or 15 grains]; Water, hot, *ten cubic centimeters* [or 162 minims]; Benzoinated Lard, *seventy-seven grammes* [or 2 ounces av., 313 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Potassium Iodide and the Sodium Hyposulphite in the hot Water, then mix the solution with the Benzoinated Lard." *U. S.*

"Potassium Iodide, 50 *grains* or 5 grammes; Potassium Carbonate, 3 *grains* or 0·3 gramme; Distilled Water, 47 *grains* or 4·7 grammes; Benzoated Lard, 400 *grains* or 40 grammes. Dissolve the Potassium Iodide and Potassium Carbonate in the Distilled Water; mix the solution, gradually, with the Benzoated Lard, in a slightly warmed mortar." *Br.*

The U. S. preparation of 1870 was apt to become discolored by time in consequence of the liberation of iodine. This was due to rancidity in the lard, and the slightest change in the fat would produce some discoloration. It was prevented in the U. S. P. 1880 by the sodium hyposulphite, which also produces traces of sodium iodide and sulphur. It is said that the same object may be attained by mixing two drops of liquor potassæ with each ounce of the freshly prepared ointment. (*A. J. P.*, xxiii. 123.) The addition of potassium carbonate by the present Br. Pharmacopœia is no doubt made with this object. The *Bulletin de Pharmacie du Nord* recommended a concentrated solution of potassium iodide in glycerin as a basis for this ointment. One gramme of the salt is dissolved in two and a half grammes of hot glycerin, and the solution mixed with the fatty constituent in the proper proportion. The advantages of this method are that the ointment is free from crystals, and the salt more readily absorbed. The glycerin would probably not be objectionable in most cases, and potassium carbonate could be added, if desired. Ointment of potassium iodide is employed for the discussion of *goitres, scrofulous tumors,* and other *indolent swellings,* and is sometimes preferred to the ointment of iodine, as it does not, like that, discolor the skin.

UNGUENTUM STAPHISAGRIÆ. Br. Stavesacre Ointment.

(ŲN-GUĔN'TUM STĂPH-Į-SĀ'GRĮ-Æ.)

"Stavesacre Seeds, 2 *ounces* (Imperial) or 40 grammes; Yellow Beeswax, 1 *ounce* (Imp.) or 20 grammes; Benzoated Lard, 8½ *ounces* (Imp.) or 170 grammes. Crush the Stavesacre Seeds; digest the crushed seeds with the Benzoated Lard on a water-bath for two hours; strain

and press through calico; add the Beeswax to the liquid; heat gently to dissolve; stir until cold." *Br.*

This ointment is half the strength of that official in the Br. Ph. 1885; it is said to be non-irritant, and is largely used in Great Britain for destroying *body-lice*, also in *scabies*, *prurigo*, and some other *cutaneous affections*.

UNGUENTUM STRAMONII. U. S. Stramonium Ointment.

(ŲN-GUĔN'TUM STRĄ-MŌ'NI-Ī.)

Pommade de Stramoine, *Fr.;* Stechapfelsalbe, *G.*

"Extract of Stramonium Seed, *ten grammes* [or 154 grains]; Diluted Alcohol, *five grammes* [or 77 grains]; Benzoinated Lard, *eighty-five grammes* [or 3 ounces av.], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Extract with the Diluted Alcohol until it is uniformly soft; then gradually add the Benzoinated Lard, and mix thoroughly." *U. S.*

This is a more certain preparation than that of the former editions of the U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard. For remarks by Mr. A. P. Sharp, of Baltimore, on the preparation of this ointment, see *A. J. P.* (xxvii. 391). A useful anodyne application in *irritable ulcers*, *painful hemorrhoids*, and certain *cutaneous eruptions*.

UNGUENTUM SULPHURIS. U. S., Br. Sulphur Ointment.

(ŲN-GUĔN'TUM SŬL'PHŬ-RĬS.)

Unguentum Sulfuratum Simplex, *P. G.;* Pommade soufrée, *Fr.;* Schwefelsalbe, *G.*

"Washed Sulphur, *three hundred grammes* [or 10 ounces av., 255 grains]; Benzoinated Lard, *seven hundred grammes* [or 24 ounces av., 303 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the Washed Sulphur with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Sublimed Sulphur, finely sifted, 1 *ounce* (Imperial) or 30 grammes; Benzoated Lard, 9 *ounces* (Imp.) or 270 grammes. Mix." *Br.*

Washed sulphur has been substituted in the U. S. P. 1890 for the sublimed sulphur of the former Pharmacopœia: the change is of questionable utility, as the products resulting from the slight decomposition in sublimed sulphur have value as parasiticides. Sulphur ointment is a specific for the *itch*. It should be applied every night over the whole surface till the complaint is cured. Four applications are generally sufficient to effect a cure. Sulphur ointment applied freely over the variolous eruption in its early stage is said to prevent the maturation of the pustules and the consequent pitting. Its disagreeable odor may be partially concealed by oil of lemon or oil of bergamot.*

UNGUENTUM SULPHURIS IODIDI. Br. Sulphur Iodide Ointment.

(ŲN-GUĔN'TUM SŬL'PHŬ-RĬS Ī-ŎD'Į-DĪ.)

Pommade d'Iodure de Soufre, *Fr.;* Jodschwefelsalbe, *G.*

"Sulphur Iodide, 20 *grains* or 2 grammes; Glycerin, 20 *grains* or 2 grammes; Benzoated Lard, 460 *grains* or 46 grammes. Triturate the Sulphur Iodide and Glycerin in a slightly warmed mortar until a smooth paste results; gradually add the Benzoated Lard; stir until cold." *Br.*

This ointment is no longer official in the U. S. Pharmacopœia: that of the U. S. P. 1870 was made by rubbing thirty grains of sulphur iodide with a troyounce of lard, gradually added, until thoroughly mixed.

This is admirably adapted, as a local remedy, to the treatment of *chronic cutaneous eruptions* unattended with inflammation, and is especially useful in *psoriasis*, *lepra*, *porrigo*, and the very advanced dry stages of *eczema* and *impetigo*.

UNGUENTUM VERATRINÆ. U. S., Br. Veratrine Ointment.

(ŲN-GUĔN'TUM VĔR-Ą-TRĪ'NÆ.)

Unguentum Veratriæ, *U. S.* 1870; Pommade de Vératrine, *Fr.;* Veratrinsalbe, *G.*

"Veratrine, *four grammes* [or 62 grains]; Olive Oil, *six grammes* [or 93 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces

* *Unguentum Sulphuris Alkalinum.* U. S. 1880. *Alkaline Sulphur Ointment.* "Washed Sulphur, *twenty parts* [or ninety-six grains]; Carbonate of Potassium, *ten parts* [or forty-eight grains]; Water, *five parts* [or half a fluidrachm]; Benzoinated Lard, *sixty-five parts* [or three hundred and twelve grains], To make *one hundred parts* [or about one ounce]. Rub the Sulphur with the Carbonate of Potassium and the Water, gradually add the Benzoinated Lard, and mix thoroughly." This ointment, dropped at the U. S. P. 1890 revision, is useful in *scabies* and other *skin affections*.

av., 231 grains]. Rub the Veratrine with the Olive Oil, in a mortar; then gradually add the Benzoinated Lard, and mix thoroughly." *U. S.*

"Veratrine, 10 *grains* or 0.5 gramme; Oleic Acid, 40 *grains* or 2 grammes; Lard, 450 *grains* or 22·5 grammes. Rub the Veratrine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

For the uses of Veratrine ointment, see *Veratrina* and *Oleatum Veratrinæ*. Notice should be taken of the fact that the U. S. ointment is twice as strong as the British. It should be employed with caution, especially in the case of children.

UNGUENTUM ZINCI OLEATIS. Br. Zinc Oleate Ointment.

(ŲN-GUĔN'TUM ZĬN'ÇĪ Ō-LĘ-Ā'TĬS.)

"Zinc Sulphate, 2 *ounces* (Imperial) or 60 grammes; Hard Soap, in shavings, 4 *ounces* (Imp.) or 120 grammes; Distilled Water, boiling, Soft Paraffin, white, of each *a sufficient quantity*. Dissolve the Zinc Sulphate in *four fluid ounces* (Imp. meas.) or one hundred and twenty cubic centimetres of the Distilled Water. Dissolve the Hard Soap in *forty fluid ounces* (Imp. meas.) or twelve hundred cubic centimetres of the Distilled Water. Mix the solutions; collect the precipitated zinc oleate; wash with hot Distilled Water until the washings afford little or no reaction for sulphate; dry on a water-bath and mix with an equal weight of the Soft Paraffin, melted; stir until cold." *Br.*

This ointment was radically changed in the Br. Ph. 1898 revision: instead of using zinc oleate made from oleic acid and zinc oxide, a process is ordered which directs the zinc oleate to be made by double decomposition between zinc sulphate and sodium oleo-stearate (hard soap). The product is a white, fine precipitate; it is, however, not a pure oleate, but a zinc oleo-stearate or oleo-palmitate.

This preparation has therapeutic properties similar to those of the ointment of zinc oxide, but is a little more stimulating. It is especially useful in *chronic eczema* and similar *cutaneous eruptions*.

UNGUENTUM ZINCI OXIDI. U. S. (Br.) Ointment of Zinc Oxide.

(ŲN-GUĔN'TUM ZĬN'ÇĪ ŎX'Į-DĪ.)

Unguentum Zinci, *Br.*, Ointment of Zinc; Unguentum Zinci, *P. G.;* Unguentum de Nihilo Albo; Pommade d'Oxyde de Zinc, Cérat épulotique, *Fr.;* Zinksalbe, *G.*

"Zinc Oxide, *two hundred grammes* [or 7 ounces av., 24 grains]; Benzoinated Lard, *eight hundred grammes* [or 28 ounces av., 96 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Sift the Zinc Oxide through a No. 20 sieve, upon the surface of the Benzoinated Lard, previously melted, and incorporate it by stirring, which is to be continued until the Ointment is cool." *U. S.*

"Zinc Oxide, finely sifted, 3 *ounces* (Imperial) or 75 grammes; Benzoated Lard, 17 *ounces* (Imp.) or 425 grammes. Add the Zinc Oxide gradually to the Benzoated Lard, previously melted at a low temperature; stir the mixture constantly until cold." *Br.*

The British ointment is weaker in the proportion of zinc oxide than that of the U. S. Pharmacopœia, the former containing about 15 per cent., the latter 20 per cent. *Commercial* zinc oxide should not be used, as it is usually gritty, and it is difficult to make a smooth ointment with it; the many expedients that have been suggested by various writers, such as the use of a paint-mill or of a flat-iron, or trituration with oil or with glycerin, are unnecessary if official or Hubbuck's zinc oxide is used and the official formula followed. Zinc oxide is a difficult powder to sift. Care should be used to employ a coarse sieve (No. 20) as officially directed. Cerate of zinc carbonate is no longer official.*

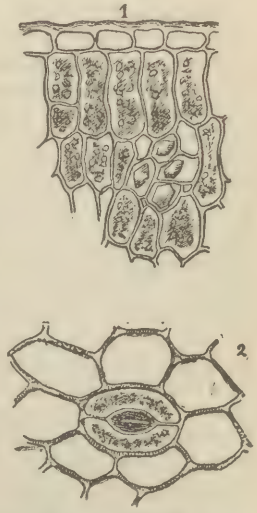
This ointment is employed as a mild astringent application in *chronic ophthalmia* with a relaxed state of the vessels, in *cutaneous eruptions*, and in *sore nipples* and other cases of *exco-*

* *Ceratum Zinci Carbonatis.* U. S. 1870. *Cerate of Carbonate of Zinc.* "Take of Precipitated Carbonate of Zinc *two troyounces;* Ointment of Lard *ten troyounces.* Mix them." This preparation is an imitation of the cerate recommended by Turner, and is intended as a substitute for the former Ceratum Zinci Carbonatis and the still more ancient Ceratum Calaminæ of the U. S. Pharmacopœia, as being more reliable, in consequence of the frequent falsification of calamine. It is mildly astringent, and is used in *excoriations* and superficial *ulcerations* produced by the chafing of the skin, irritating secretions, burns, or other causes.

Ceratum Calaminæ. U. S. 1850. *Turner's Cerate.* The following is the old official process. "Take of Prepared Calamine, Yellow Wax, each, *three ounces;* Lard *a pound.* Melt the Lard and Wax together, and when on cooling they begin to thicken, add the Calamine, and stir the mixture constantly until cool." The uses of this cerate are the same as those mentioned above.

riation or *ulceration*. It has taken the place of the discarded *unguentum tutiæ*, or *tutty ointment*, prepared from tutty, or impure zinc oxide, by mixing it with five parts of simple ointment.

UVA URSI. U. S. (Br.) Uva Ursi. [Bearberry.]



(Ū'VĄ ŬR'SĪ.)

"The leaves of Arctostaphylos Uva Ursi (Linné), Sprengel (nat. ord. Ericaceæ)." *U. S.*
"The dried leaves of Arctostaphylos Uva-ursi, Spreng." *Br.*

"**Uvæ Ursi Folia**, *Br.;* Feuilles de Busserole, Busserole, Raisin d'Ours, *Fr.;* Bärentraube, Bärentraubenblätter, *G.;* Corbezzolo, Uva Ursina, *It.;* Gayuba, *Sp.*

Arctostaphylos uva ursi. Sprengel, *Syst.* ii. (1825) 287; Carson, *Illust. of Med. Bot.* i. 61, pl. 52; *B. & T.* 163.—*Arbutus uva ursi.* L. *Sp. Pl.* (1753) 395. The *uva ursi*, or *bearberry*, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upward for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, or oblong-spatulate, acute at the base, obtuse at the apex, entire, with a rounded margin, thick, coriaceous, smooth, shining, deep green on their upper surface, paler and covered with a net-work of veins beneath; furnished especially near the margin or near the midrib with minute hairs, which are usually abundant in young leaves, but may be few or absent in old leaves, especially those which have been much handled. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is ovate or urceolate, reddish white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the germ round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy red berry, with an insipid mealy pulp and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes and high mountains of Europe, Asia, and America. On the American continent it extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe, but are also collected within our own limits; and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and only the green leaves selected. In Europe the uva ursi is adulterated with the inert leaves of the *Vaccinium vitis idæa:* these may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and their dotted under surface. Leaves of the *Chimaphila umbellata*, sometimes found among the uva ursi, may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Leaves of Uva Ursi. 1, transverse section of the upper surface of the leaf, showing epithelial layer with parenchymatous cells and raphides; 2, epidermis of the under surface, showing stoma.

Another species of Arctostaphylos is *A. glauca*, Lindl., a small tree or shrub indigenous in California, where it generally grows in dry and rocky places on the west of the mountain-ranges. The leaves are highly esteemed as a remedy in *diarrhœa* and *gonorrhœa*, being used in the form of decoction. Chemically examined by Mr. John Henry Flint, they were found to contain 9·8 per cent. of tannin; and the ashes of the incinerated leaves, amounting to 0·6 per cent., contained potassium, calcium, magnesium, and iron. A crystalline principle has been discovered in the leaves, which Mr. Flint found to be arbutin. (*A. J. P.*, May, 1873, p. 197.)

Properties. Uva ursi is inodorous when fresh, but when dried and powdered acquires a smell not unlike that of hay. Its taste is bitterish, strongly astringent, and ultimately sweetish. It affords a light-brown, greenish-yellow powder. It is officially described as "very short-stalked, obovate or oblong-spatulate, coriaceous, from 15 to 20 Mm. long, and 5 to 8 Mm. broad, obtuse, slightly revolute on the margin, upper surface with depressed veins; lower surface distinctly reticulate; odor faint, hay-like; taste strongly astringent, and somewhat bitter." *U. S.* Water and official alcohol extract the active principles of uva ursi. Among its ingredients are tannic and gallic acids, bitter extractive,

resin, gum, fatty matter, a volatile oil, and salts of potassa and lime. The tannic acid is so abundant that the leaves are used for tanning in Russia. Neither tannic nor gallic acid exists in the leaves of the *Vaccinium vitis idæa*.

A crystallizable principle was extracted from uvi ursi by Mr. J. C. C. Hughes, to which he gave the name *ursin*, but Jungmann (*A. J. P.*, May, 1871, p. 205) afterwards showed it to be only impure arbutin. Kawalier (*Chem. Gaz.*, 1853, p. 61) obtained *arbutin*, $C_{12}H_{15}O_7$, by precipitating the decoction with lead acetate, filtering, treating the liquid with hydrogen sulphide, again filtering, evaporating to the consistence of syrup, and allowing the product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother-liquor to drain off, and then pressed, yielded nearly colorless crystals, which were purified by solution in boiling water and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colorless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of 212° F., but fusible at 167° to 168° C., without action on vegetable colors, and not precipitated by ferric salts or by lead acetate or subacetate. It is a glucoside, being resolvable by emulsin, or more rapidly by boiling with sulphuric acid, into glucose and *hydroquinone*, $C_6H_6O_2$ (*arctuvine* of Kawalier). The occurrence of methylhydroquinone among the products of decomposition led Hlasiwetz and Habermann to give the formula $C_{25}H_{34}O_{14}$ to arbutin, but Schiff showed that this was because arbutin was almost always accompanied by *methylarbutin*, $C_{12}H_{15}(CH_3)O_7 + H_2O$. This compound has been made synthetically by Schiff (*Ber. der Chem. Ges.*, 1882, p. 1841) by acting upon arbutin with methyliodide and potassium hydrate in methylalcohol solution, and purely synthetically by Michael (*Ber. der Chem. Ges.*, 1885, p. 118) by the action of methylhydroquinone and acetochlorhydrose. It is decomposed by dilute acids into glucose and methylhydroquinone. Upon heating 1 part of arbutin with 8 parts of manganese oxide, 2 parts of sulphuric acid, and 1 part of water, it gives off the penetrating odor of quinone. The watery solution is rendered blue by a small quantity of solution of ferric chloride, and green by a larger quantity. No precipitate is produced by either acids or alkalies. It blackens ammoniacal solution of silver nitrate after boiling with dilute sulphuric acid, and throws down cuprous oxide from alkaline copper solutions upon heating. It dissolves in sulphuric acid, forming a colorless solution, turning red after a short time; a trace of nitric acid turns this solution yellow-brown. An aqueous solution (1 in 20) is not changed by hydrogen sulphide. A good test for arbutin is that of Julius Jungmann, as follows. When phosphomolybdic acid is added to a solution of arbutin previously rendered alkaline by ammonia or other alkali, a blue color is produced, which is deep when the solutions are strong, but observable even when they are very dilute. (*A. J. P.*, May, 1871, p. 204.)* After the extraction of arbutin, there is obtained from the mother-liquor *ericolin*, $C_{34}H_{56}O_{21}$.† Another crystallizable principle has been discovered by Trommsdorff, who calls it *urson*, $C_{30}H_{48}O_3$. It appears to be of a resinous character, although it can be obtained in silky needles, being tasteless and inodorous, insoluble in water, difficultly soluble in alcohol and ether, fusible, at a higher temperature volatilizable, and inflammable in the air. It is obtained by treating uva ursi with a very small quantity of ether by percolation, allowing the ether to evaporate, washing the crystalline extract with ether, and recrystallizing from alcohol. (*A. J. P.*, xxvii. 334.)

A. G. Perkin has obtained from the leaves of *uva ursi* a yellow coloring principle of the composition $C_{15}H_{10}O_7$, crystallizing in glistening yellow needles. On fusion with alkali phloro-

* *Arbutin.* Besides being a constituent of the two species of Arctostaphylos above mentioned, this principle is somewhat widely diffused in other plants. It is especially found in those belonging to the natural order Ericaceæ, as *Chimaphila umbellata* (L.), Nutt., *Chimaphila maculata* (L.), Pursh, *Epigæa repens*, L., and *Gaultheria procumbens*, L. In some others it has been supposed to exist because among the products of the dry distillation of their extract a principle has been found denominated *hydroquinone*, which is one of the products of the destructive distillation of arbutin; but, as kinic acid yields the same substance in the same way, the inference in relation to the existence of arbutin in the plants is somewhat uncertain. Nevertheless, as kinic acid yields *pyrocatechin* along with hydroquinone, while arbutin gives only the latter, a method of distinguishing the two is afforded; the plants from which only hydroquinone is obtained probably contain arbutin; while, if both principles are obtained, kinic acid is probably in the plant. (*A. J. P.*, 1874, 314.)

Analysis of Vaccinium vitis idæa, or *Red whortleberry*, by Dr. Gräger. The berries contain 10·185 per cent. of soluble matter, 4·204 of insoluble matter (cellulose, pectin, etc.), and 85·611 of water. The expressed juice yielded 1·975 per cent. of free organic acid (citric and malic), 5·185 of sugar, 0·476 of tannin, 2·333 of albuminous and pectinaceous substances, suspended fat, etc., 0·216 of inorganic bases (potassa, lime, magnesia, iron), and 89·815 of water. The insoluble residue yielded 0.102 per cent. of ashes containing calcium sulphate and phosphate, silicic acid, and ferric oxide. (*A. J. P.*, 1871, 543.)

† *Ericolin* is a wide-spread constituent of ericaceous plants, having been found in *Ledum palustre*, L., *Calluna vulgaris* (L.), Salisb., *Rhododendron ferrugineum*, L., etc: for chemical discussion, see R. Thal, *Inaug. Diss.*, Dorpat, 1883.

glucinol and protocatechuic acid were formed. Though resembling quercetin in these points, it forms deep green solutions with dilute potassium hydrate. (*A. J. P.*, 1898, 584.)

Medical Properties and Uses. Uva ursi is astringent and tonic, and is thought to have a specific direction to the urinary organs, for the complaints of which it is chiefly used. It alters the color of the urine, and its astringent principle has been detected in that secretion. Though known to the ancients, it had passed into almost entire neglect, till its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in *gravel*, partly, perhaps, by a direct action on the kidneys and bladder, partly by giving tone to the digestive organs. In *chronic nephritis* it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of *ulceration in the kidneys, bladder, or urinary passages*. *Catarrh of the bladder*, *incontinence of urine*, *gleet*, *leucorrhœa*, and *menorrhagia* are also among the diseases in which it has occasionally proved serviceable. The dose of the powder is from a scruple to a drachm (1·3–3·9 Gm.), to be repeated three or four times a day; but the fluid extract is always preferred. According to Mr. Hues, arbutin in the dose of one grain is a powerful diuretic: that it is free from poisonous properties was shown by Jolonowski, who took in forty-eight hours over two hundred grains of it without discomfort. After large doses the urine varies in color from pale greenish to dark greenish brown. The discoloration is due to the breaking up of the arbutin in the body into glucose and hydroquinone, the change probably occurring in the kidneys. There is considerable clinical testimony to show that arbutin is a useful remedy in *cystitis* when given in doses of ten to fifteen grains a day. The influence of the drug has been supposed to be due to its conversion into hydroquinone, which, as is well known, is a powerful disinfectant and antiferment. H. Paschkis states that only the smaller portion of the arbutin is changed into hydroquinone, and this is confirmed by Laurentz. The extract of uva ursi contains only three and a half per cent. of arbutin to sixteen per cent. of tannic acid; there is also a volatile oil, so that arbutin cannot be considered fully to represent the drug. One grain of the extract ought to represent about four grains of the crude leaves, and from half a drachm to a drachm of it may be given three or four times a day.

VALERIANA. U. S. (Br.) Valerian.

(VĀ-LĒ-RĬ-Ā'NĀ.)

"The rhizome and roots of Valeriana officinalis, Linné (nat. ord. Valerianeæ)." *U. S.*
"The dried erect rhizome and roots of Valeriana officinalis, Linn. Collected in the autumn." *Br.*

Valerianæ Rhizoma, *Br.;* Valerian Root; Radix Valerianæ Minoris; Racine de Valériane, Valériane, *Fr.;* Wilde Baldrianwurzel, Baldrianwurzel, *G.;* Valeriana silvestre, *It.;* Valerian silvestre, *Sp.*

Valeriana officinalis. L. *Sp. Pl.* (1753) 31; Willd. *Sp. Plant.* i. 177; *B. & T.* 146. The *official* or *great wild valerian* is a large, handsome, herbaceous plant, with a perennial root, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stems are attached by short, broad sheaths; the radical leaves are larger and stand on long footstalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-colored, agreeably odorous, and disposed in terminal corymbs interspersed with pear-shaped pointed bracts. The number of the stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris*, L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves. It has been generally believed to be superior to the others in medicinal virtue; but A. Buchner has demonstrated that the dried roots of the variety which grows in low moist grounds are in no respect inferior. (*Pharm. Centralblatt*, June, 1852, 429.)*

* *Valeriana mexicana.* D. C. According to the *Nueva Farmacopea Mexicana*, the roots of this plant contain a large percentage of valerianic acid, which they yield readily and economically. In Mexican commerce they are said to occur in slices or fleshy disks about four centimetres or more in diameter, or in voluminous tubercles. Externally the color is grayish yellow, internally yellow; the odor is strong and disagreeable, the taste bitter. R. McLaughlin (*A. J. P.*, 1893, 329) found 3·3 per cent. of oil in the Mexican valerian root. (See also *Schimmel's Report*, April, 1897.)

Japanese Valerian. Kesso root. This, formerly believed to be the product of *Patrinia scabiosæfolia*, Link, is now thought to be obtained from a variety of *V. officinalis*. It yields a volatile oil. (*P. J. Tr.*, xx. 837, xxi. 1069.)

The root should be collected in spring, before the stem begins to shoot, or in the autumn, when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous long, slender, brittle, cylindrical, thick-barked rootlets, issuing from a tuberculated head or rhizome, which is "from 2 to 4 Cm. long, and 1 to 2 Cm. thick, upright, subglobular or obconical, truncate at both ends, brown or yellowish-brown, internally whitish or pale brownish, with a narrow circle of white wood under the thin bark. Roots numerous, slender, brittle, brown, with a thick bark, and slender, ligneous cord. Odor peculiar, becoming stronger and unpleasant on keeping; taste camphoraceous and somewhat bitter." *U. S.* As brought to this country, it frequently has portions of the stem attached. The English is superior to that from the continent of Europe. Valerian of good quality has been produced by the Shakers at Enfield, New Hampshire, also in Northern Vermont and New York. Mr. Thomas Doliber obtained from the American root 28·97 per cent. of alcoholic extract, and from the English 17·59 per cent., and states that the native drug has, in our market, almost superseded the European. (*A. J. P.*, 1867, p. 70.)

Properties. The color of the root is externally yellowish or brown, internally white. The powder is yellowish gray. The odor, which in the fresh root is slight, in the dried is strong and highly characteristic, and, though rather pleasant to many persons, is very disagreeable to others. Cats are strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorff found it to consist of 1·2 parts of volatile oil, 12·5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions, 18·75 of gum, 6·25 of a soft odorous resin, and 63 of lignin. Runge found in it a peculiar fixed acid, which produced with bases white salts, becoming green on exposure to the air. (*Chem. Gaz.*, No. 170, p. 452.) Of these constituents the most important is the *volatile oil.** It is of a pale greenish color, of the sp. gr. 0·934, with the pungent odor of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Bruylants (*Ber. Chem. Ges.*, 1878, p. 449) has obtained from oil of valerian, 1st, a hydrocarbon or terpene, $C_{10}H_{16}$, boiling at 157° C.; 2d, a liquid compound, $C_{10}H_{18}O$, which by means of chromic acid affords common camphor, and formic, acetic, and valerianic acids, which are met with in old valerian root, owing no doubt to the slow oxidation of the compound $C_{10}H_{18}O$; 3d, a crystalline compound of the same composition, which in the root is probably combined with the three organic acids mentioned, constituting with them compound ethers; 4th, at from 285° to 290° C., a greenish, syrupy oil, which when rectified is colorless, and seems to have the composition of a *borneol oxide*, $(C_{10}H_{17})_2O$. Schimmel & Co. (*Semi-annual Report*, April, 1897) summarize the most recent researches upon valerian oil from different sources. In the oil from Dutch and Thuringian roots, the amount varying from 0·5 to 1 per cent., they find pinene, camphene, borneol, bornyl formate, bornyl acetate, and bornyl isovalerianate, together with a sesquiterpene and an alcohol, $C_{10}H_{20}O_2$. In the oil from Japanese roots (amounting to from 6 to 6·5 per cent.) (*Kesso oil*), they find pinene, camphene, dipentene, terpineol, borneol, bornyl acetate, bornyl isovalerianate, and kessyl acetate. Trommsdorff ascertained the existence in the oil of *valerianic acid.* This is a colorless volatile liquid, of an oleaginous consistence, having an odor analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odor of the acid. (*Journ. de Pharm.*, xx. 316.) The results of Bruylants just given show that the acid does not exist free in the oil, but is produced by the decomposition of its borneol ether. Valerianic acid is obtained by distilling the impure oil from magnesium carbonate, decomposing by sulphuric acid the valerianate of magnesium which remains, and again distilling. The following process by Messrs. T. and H. Smith, of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of M. Rabourdin. Boil the root for three or four hours with rather more than its bulk of water in which an ounce of sodium carbonate is dissolved for every pound of the root, replacing the water as it evaporates. Ex-

* *Oleum Valerianæ.* U. S. 1880. *Oil of Valerian.* (*Essence de Valériane*, Fr.; *Baldrianöl*, G.) This volatile oil is obtained from the root of *Valeriana officinalis* by the usual process of distillation with water. According to Zeller, the dried root of the best quality yields 1·64 per cent. of the oil. Very good oil has been distilled from the root cultivated in this country. As first procured, it is of a pale greenish color, of the sp. gr. 0·934, with a pungent odor of valerian, and an aromatic taste. Upon exposure it becomes yellow and viscid. "A slightly acid reaction. Sp. gr. about 0·950. It is readily soluble in alcohol." The oil of valerian exercises the same influence as does the root on the nervous system, and is frequently administered as a substitute for it, in the dose of four or five drops (0·24–0·3 C.c.).

press strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil till three-fourths of the liquid have passed over. Neutralize this with sodium carbonate, concentrate the liquid, decompose the sodium valerianate contained in it by sulphuric acid, and separate the valerianic acid set free by a separatory funnel, or by distillation. (*A. J. P.*, xvii. 253.) M. Lefort obtains the acid by the rapid oxidation of the volatile oil. He distils 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of potassium dichromate, and has thus procured a larger proportion of acid than by any other process. (*Journ. de Pharm.*, 3e sér., x. 194.)

The roots of *Valeriana Phu*, L., and *V. dioica*, L., are said to be sometimes mingled with those of the official plant; but the adulteration is attended with no serious consequences, as, though much weaker than the genuine valerian, they possess similar properties. The same cannot be said of the roots of several of the Ranunculaceæ, which, according to Ebermayer, are sometimes fraudulently substituted in Germany. They may be readily detected by their want of the peculiar odor of the official root. According to M. O. Raveil, the valerian in the markets of Paris is largely adulterated with the roots of *scabious* (*Scabiosa succisa*, L., and *S. arvensis*, L.). They are shorter than the genuine root, with larger radicles, less rough, little or not at all striated, very brittle, with a white amylaceous fracture. The roots are inodorous in themselves, but are very apt to acquire smell from contact with the valerian. (*Journ. de Pharm.*, xxvi. 209.)

Medical Properties and Uses. Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effects. In large doses it produces a sense of heaviness and dull pain in the head, with various other effects indicating nervous disturbance. The oil, largely taken, is said by M. Barailer, from his own observation, to produce dulness of intellect, drowsiness ending in deep sleep, reduced frequency of pulse, and increased flow of urine. (See *A. J. P.*, 1861, p. 239.) It is useful in cases of irregular nervous action, when not connected with inflammation or an excited condition of the system. Among the complaints in which it has been particularly recommended are *hysteria*, *hypochondriasis*, *hemicrania*, and *low forms of fever*, attended with restlessness, morbid vigilance, or other nervous disorder. As the virtues of valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe; and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five drops (0·24–0·3 C.c.). Valerianic acid also has been used internally. (See *Acidum Valerianicum*.) Landerer says that, in his experience, the acid prepared from the root is preferable therapeutically to the artificial acid: this preference may be due to the presence of impurities, having medicinal properties, which are found in the acid from the root.

VANILLA. U. S. Vanilla.*

(VĂ-NĬL'LĂ.)

"The fruit of Vanilla planifolia, Andrews (nat. ord. Orchideæ)." *U. S.*

Fructus (s. Silique) Vanille, *P. G.*; Vanille, *Fr.*, *G.*

Vanilla planifolia. Andrews, *Bot. Repository*, t. 538 (1808); *B. & T.* 272. This is a fleshy, dark green, perennial climbing plant, with a very long, smooth, dark green stem, much branched, and furnished at the nodes with aerial roots, which cling to the tree or the wooden framework supporting the plant. The dark green, tough leaves are alternate, oval, sessile, attenuate at the apex, fleshy, and veinless. The pale greenish-yellow, sessile flowers are about two inches in diameter, and occur in loose, axillary racemes of eight or ten. The fruit is a slender pod, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds.† The plant is a native of the West Indies, Mexico, and South America, and is widely

* *Vanillons*, said to be uncultivated or wild vanillas, are chiefly used by manufacturers of tobacco, sachet powders, etc. They are from 4 to 5 inches in length, from ⅜ to ½ or even 1 inch in diameter, frequently sharply angled, exhibiting almost a triangular shape on cross-sectioning. They are of nearly the same diameter for the greater portion of their length, being attenuated at both ends. They are brown to red-brown in color, and longitudinally ridged. The transverse markings due to their being wrapped with twine during the process of curing give them a curious twisted appearance. They are generally split open and lack almost entirely the odor of vanillin, their odor being compared to a cross between a fermented sugar and a heliotrope odor. They are devoid of any crystalline efflorescence.

† The following account of the structure of vanilla fruit is adapted from that of Prof. S. E. Jelliffe. The transverse section of the vanilla bean displays a thick-walled, irregular triangular cavity, into which the placenta, sup-

cultivated. It is stated to be grown under glass in England and France, and at Liège, with commercial success. (*A. J. P.*, xlvi. 419.) Doubts, however, exist whether commercial vanilla is entirely derived from this species, and the United States Pharmacopœia formerly ascribed it to *V. aromatica*, Swartz, which is specifically characterized by its ovate, oblong, nerved, opposite leaves, its waxy sepals, its acute lip, and its very long cylindrical capsules. According to R. A. Rolfe, *V. pompona*, Schiede, yields the Guadeloupe variety, and *V. gardneri*, Rolfe, is said to yield Brazilian and Bahia vanilla. *V. appendiculata*, Rolfe, and *V. odorata*, Presl., produce aromatic fruits, but are not known to be cultivated; whilst *V. pharantha*, which possesses but little perfume, is under cultivation at Jamaica and Trinidad. (*Kew Bulletin*, No. 104, 169.) *V. guayanensis* and *V. palmarum* are also said to yield an aromatic fruit. (See also below.)

In Mexico the vanilla plant flourishes on the eastern coast, in the States of Vera Cruz and Oaxaca. It begins to bear fruit in three years, and continues to bear for thirty or forty years. The vanilla of commerce is chiefly derived from plants artificially grown by a very simple method of cultivation. All that is necessary is to attach a slip taken from the lower part of the stem to the trunk or branch of a tree, or to some other support. The plant immediately fastens upon the bark of the tree, and sends out aerial roots which fix themselves upon the ground. It does not, however, derive food from the tree: in some places where cultivated it is planted on trellises. The vanilla bean is gathered in the late autumn, when nearly matured, in the form of a large green pod, and immediately submitted to the process of drying and curing, which is said to reduce its weight eighty per cent. and to require three or four months for completion. During this process the beans are placed in rows on mats or planks in the air during the day, and in the evening put into caldrons and covered with blankets, so as to undergo a kind of sweating process, during which an oil is said to ooze from them, and to be collected, so that when the beans are dried and ready for bundling each of them may be rubbed with it. When thoroughly cured, the pods are assorted, tied into bundles which are surrounded with sheet lead or placed in small metallic boxes, and sent into market.

The cultivation of the vanilla has extended from South America almost over the whole of the tropics. Holland is supplied from the Java plantations; France from Tahiti, Madagascar, Réunion, Guadeloupe, and other of her colonies. From Mauritius and the Seychelles the product goes to London. During the last twenty-five years there has been a great increase in the amount of vanilla consumed in the United States, although the maximum importation occurred in 1893. In 1897 over 156,000 pounds were imported; of these 58,521 pounds were Bourbon vanilla, 65,378 were Mexican, and 32,191 Tahitan. The Mexican variety is sold at almost double the price of the Bourbon, and the Bourbon at almost double the price of the Tahitan, although it is stated that the Bourbon beans are improving and the Mexican deteriorating in quality. The Tahitan vanilla is much injured by carelessness in the process of curing. For an account of commercial vanillas, see *A. J. P.*, 1892, 289.

Of *Mexican vanilla*,* the first quality occurs in pods from eight to ten inches long, flattened, two-eighths to three-eighths of an inch in diameter, with the lower end slightly attenuated, the upper end gradually tapering for about a quarter of the length of the pod, usually curved and slightly twisted near the point. The color is dark brown, the pods fairly plump, the surface ridged longitudinally, and with an incrustation of fine crystals beginning at the

porting two rows of fine black seeds, projects. The wall of the ovary is lined with minute papillæ bearing unicellular papillose hairs, which project into the central cavity and are believed to secrete the materials out of which the vanillin is elaborated. Beneath the epicarp or external part of the fruit is a lax tissue, in which there is an oily substance with the characteristics of vanillin and numerous fine acicular crystals of calcium oxalate. The polygonal mesocarpal cells are for the most part finely pitted, some irregularly marked. The vascular bundles of the mesophyll are irregularly scattered or radially or tangentially arranged. Spiral ducts are abundant, annular ducts few. In the tissue of the mesophyll irregular resinous masses and prisms of vanillin occur.

* Of the Mexican vanillas the most valuable variety, called *ley*, or *vainilla mansa*, by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odor, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. In it are more or less numerous, minute crystals. Another variety, called *vainilla simarona* by the Spaniards, is smaller, of a lighter color, and less aromatic. The pods are said to be very dry and to contain no vanillin. (*Nueva Farmacopea Mexicana.*) According to Schiede, it is yielded by a distinct species, the *Vanilla sylvestris* (Schiede). A third variety is the *vainilla pompona* of the Spaniards (*boba vainilla*, or *plátano vainilla*). In this, the pods are from five to seven inches long, from six to nine lines broad, shaped somewhat like a plantain, almost always open, very dark brown or nearly black, soft, viscid, and of a strong, not very pleasant, anise-like odor. Schiede states that it is the product of the *Vanilla pompona* (Schiede). The variety *vainilla vezacate* is said to be derived from pods gathered long before maturity. (*Nueva Farmacopea Mexicana.*)

ends, gradually extending; when fresh somewhat viscid, but always roughish to the feel. For an interesting account of the Mexican vanilla plant by Charles E. Hires, see *A. J. P.*, 1893, 576.

Bourbon vanilla, produced in the Isle of Réunion to the amount of 200,000 pounds a year, resembles Mexican vanilla, but is scarcely so long in the tapering portions, is of a dark-brown almost black color, is not so firm as the Mexican, has the surface smooth and waxy, and soon becomes covered with a coating of acicular crystals known as "frost." The odor of this vanilla is said to resemble that of Tonka bean rather than that of Mexican vanilla.

The *Seychelles* and *Mauritius vanilla* (*inferior Bourbon* of the trade) has the pods about six inches in length, not over a quarter of an inch in width, and characterized by the pale color, the faint odor, and a smooth but not waxy surface.

South American or *Guadeloupe vanilla* resembles the Mexican bean, but is usually recognizable, when the bean is entire, by the latter being broad and flattened, usually half an inch or more wide, slightly tapering at the lower end, and at the upper sharply attenuated an inch or so at the point. It has a reddish-brown color, and is of a rank odor. It is very pulpy, with a surface intermediate in feel between the Bourbon and the Mexican, and having but few crystals. One variety of this vanilla, sold under the name of *vanillons*, has the odor of heliotrope, and is much used by perfumers and manufacturers of tobacco.

Tahiti vanilla, "*transplanted Mexican vanilla*," has its pods from six to seven inches long, flat, from three-eighths to half an inch wide, with a reddish-brown color. They are almost destitute of vanilla flavor, and have a rather rank odor, suggesting heliotrope.

Java vanilla, which is almost exclusively consumed in Holland, has a pod from four to six inches long, with a flavor as fine as that of the Mexican bean, and a much more powerful odor.

Vanilla beans from which the vanilla has been removed by means of a solvent are sometimes offered for sale. The fraud is to be detected by the absence of flavor and odor. Such beans, and also beans of an inferior quality, are sometimes improved in appearance and in odor by the use of benzoic acid. For the detection of this fraud the apothecary should avail himself of the fact that whilst the crystals of benzoic acid are flattened and rhomboidal and generally lie upon the bean, those of vanillin are usually acicular and stand out at right angles from the surface of the fruit.

According to Bucholz, vanilla does not yield volatile oil when distilled with water; and the aroma appears to depend on chemical changes which may take place during and after the curing of the fruit. Many years since, vanilla was analyzed by Bucholz and Vogel, the former of whom found in it a disagreeable-smelling fixed oil, a soft resin smelling feebly of vanilla when heated, a bitterish extractive resembling tannin, sugar, starch, and benzoic acid. But the characteristic odorous principle was not isolated. This object was accomplished by M. Gobley, who, by exhausting vanilla with 85-per-cent. alcohol, evaporating the resulting tincture to an extract, softening this with water, and agitating in a flask with ether so long as it gave color to that fluid, then evaporating the ethereal liquid and treating the residue with boiling water, obtained on the evaporation of the water a crop of crystals having the odor of vanilla. Purified by treatment with animal charcoal and recrystallization, the new principle appeared in the form of colorless, long, four-sided needles terminated by two faces. It has a strong odor of vanilla, with a hot, biting taste, and is frequently seen in acicular crystals upon the external surface of the bean. This compound, for which M. Gobley proposed the name *vanillin*, is now recognized as the methyl-ether of protocatechuic aldehyde, $C_6H_3\begin{cases}OCH_3\\OH\\COH,\end{cases}$ or $C_8H_8O_3$, and is known to occur somewhat diffused in the vegetable kingdom, being found in the sugar-beet and in the wood-tissue of many plants. It forms crystalline needles fusing at 80°–81° C., difficultly soluble in cold water, readily soluble in hot water, easily soluble in alcohol and ether, chloroform and carbon disulphide. It oxidizes slowly in damp air to *vanillic acid*, $C_8H_8O_4$; when heated with dilute hydrochloric acid to 200° C., it breaks up into methyl chloride and protocatechuic acid. Tiemann and Haarmann (*Ber. Ch. Ges.*, 1874), who first ascertained the true character of vanillin, also found that it could be made synthetically from *coniferin*, a glucoside contained in the cambium layer of the pine. This coniferin, $C_{16}H_{22}O_8 + 2H_2O$, or the compound $C_{10}H_{12}O_3$, which with glucose results from its decomposition, is oxidized by sulphuric acid and potassium bichromate with the production of vanillin. Artificial vanillin was made in this way from coniferin under Tiemann and Haarmann's patents, and was made by Reimer and

Tiemann from guaiacol by heating it with caustic soda and chloroform, but it is now made from *eugenol*, $C_6H_3\begin{cases}OH\\OCH_3\\CH_2.CH:CH_2\end{cases}$. This on heating with alcoholic potash is changed into *iso-eugenol*, $C_6H_3\begin{cases}OH\\OCH_3\\CH:CH.CH_3\end{cases}$, and this is then oxidized, when *vanillin*, $C_6H_3\begin{cases}OH\\OCH_3\\CHO\end{cases}$, is formed. The oxidation is effected by a variety of oxidizing agents. Sodium peroxide has been used with success, or more recently the isoeugenol sodium has been oxidized at the positive pole of an electrolytic cell, using an alkaline hydrate as the cathode liquid. Oil of cloves is therefore used as a basis for the manufacture of artificial vanillin. Although the latter substance has been largely manufactured, it does not take the place of the preparations of vanilla, the flavor and odor of the latter being greatly preferred. It passes with water in distillation. If vanilla finely divided be distilled with water, a turbid liquid passes, which becomes clear by agitation with ether, and the ether on evaporation yields crystals of vanillin. Messrs. Tiemann and Haarmann obtained from Mexican vanilla 1·69 per cent. of vanillin, from Réunion vanilla 2·48 per cent., from Java vanilla 2·75 per cent. Mr. Stokeby found in vanilla, resin, wax, a fixed oil, a brown resinous matter, tannic acid changing the salts of iron to green, gum, sugar, phosphates, and sulphates; hydrochloric acid separated from it oxalic acid, and potassa, humic acid. (*Journ de Pharm. et de Chim.*, 4e sér., iii. 76, 1866; see also paper by Clay W. Holmes, *Proc. A. P. A.*, 1887, 526.)

Medical Properties and Uses. According to Dr. Grasset, vanillin produces in frogs spinal convulsions, followed by paralysis affecting both spinal cord and motor nerves. It is said to be locally irritant, and has been suggested as a stomachic and an excito-motor remedy in doses of three-fourths of a grain. (*Archives de Pharm.*, Août, 1886.) Vanilla has been recommended in *hysteria*, but is in fact used only as a flavoring agent.*

VERATRINA. U. S., Br. Veratrine.

(VĔR-Ă-TRĪ'NĂ.)

"A mixture of alkaloids obtained from the seed of Asagræa officinalis (Schlechtendal et Chamisso), Lindley (nat. ord. Liliaceæ)." *U. S.* "An alkaloid, or mixture of alkaloids, prepared from cevadilla, the dried ripe seeds of Schœnocaulon officinale, A. Gray." *Br.*

Veratria, *U. S.* 1870; Veratria, *Br.*; Veratrium, *P. G.*; Vératrine, *Fr.*; Veratrin, *G.*

"Cevadilla of commerce, 2 *pounds* (Imperial) or 1 kilogramme; Distilled Water, Alcohol (90 per cent.), Solution of Ammonia, Hydrochloric Acid, of each *a sufficient quantity*. Macerate the cevadilla with half its weight of boiling Distilled Water, in a covered vessel, for twenty-four hours; remove the cevadilla; squeeze it; dry it thoroughly in a warm place; then beat it in a mortar, and separate the seeds from the capsules. Reduce the seeds to powder; moisten

* *Vanilla Poisoning.* Twenty years ago, Orfila recorded cases of poisoning by the eating of vanilla ices, and recently many cases have occurred both in Europe and in this country. The symptoms are those of intense gastro-intestinal irritation, and closely resemble those of cholerine. That the attacks have not simply been cholera morbus induced by the ingestion of cold ices is shown by the fact that many of the flavored dishes were pies and even simple farinaceous puddings. Elaborate chemical investigations have proved the absence of metallic poisons in the ingesta. Schroff believes the poison to be cardol derived from the oil of cashew nut placed upon the vanilla pod to preserve it, but there does not seem to be any proof of this; and it is stated that cardol could not be found in the vanilla pods obtained from the Vienna café at Berlin, where poisoning had occurred. (*P. J. Tr.*, 1874, p. 853.) Again, it has been believed that the poisoning was the result of copper derived from vessels in which the ice-cream had been preserved; but chemical analysis has disproved this. Certain chemists have been inclined to suppose that the poisoning was caused by ptomaines or other products of decomposition of the cream before freezing. Dr. Layot (*Journ. Pharm. Chem.*, x.) believes that the poisoning is really due to the vanilla, and especially to an inferior variety of bean known as "vanillon," the pods of which are free from rime, soft, viscous, and nearly always open. If, however, it be correct, as asserted (*P. J. Tr.*, xv. 241), that the poisoning has been caused by ice-cream flavored with artificial vanillin, it is almost certain that the symptoms are due to alterations in the cream itself. This is confirmed by the studies of V. C. Vaughan, who, in 1885, succeeded in isolating from cheese a peculiar poisonous ptomaine, *tyrotoxicon*. (See *A. J. P.*, 342, 1886.) Subsequently, Prof. Vaughan obtained the same poison from milk; and in June, 1886, melted ice-cream taken from a mass which had produced serious poisoning in eighteen persons, with some of the vanilla which had been used in flavoring the cream, was submitted to him for analysis. (See *A. J. P.*, xvi. 452). The ingestion of the vanilla in doses of thirty drops of an extract failed to develop in Prof. Vaughan or his assistants any symptoms, and he was able to separate the tyrotoxicon from the ice-cream itself and to poison animals with it. Dr. H. C. Wood has seen violent poisoning, with gastro-intestinal irritation and symptoms resembling those of the so-called vanilla poisoning, produced by the ingestion of stale cream puffs in which no vanilla had been put, and it is more than probable that in most cases of the so-called vanilla poisoning tyrotoxicon or some allied substance is the cause of the symptoms. If the case reported by Dr. Rosenthal be accurately stated (*P. J. Tr.*, xv. 24), it must be allowed, however, that in some instances the vanilla itself is at fault.

the powder with the Alcohol; pack firmly in a percolator; pass the Alcohol through the marc until the percolate ceases to be colored; concentrate the alcoholic solution by distillation, so long as no deposit forms, and pour the residue, while hot, into twelve times its volume of cold Distilled Water; filter through calico; wash what remains on the filter with Distilled Water, until the filtrate ceases to precipitate with Solution of Ammonia. To the filtrate add Solution of Ammonia in slight excess; let the precipitate completely subside; pour off the supernatant liquid; collect the precipitate on a filter; wash it with Distilled Water until the filtrate passes colorless; distribute the moist precipitate through *twelve fluid ounces* (Imp. meas.) or four hundred cubic centimetres of Distilled Water; add gradually, with diligent stirring, sufficient Hydrochloric Acid to make the liquid feebly but persistently acid; add *sixty grains* or four grammes of the purified animal charcoal of commerce; digest with moderate heat for twenty minutes; filter; allow the liquid to cool; add Solution of Ammonia in slight excess, and, when the precipitate has completely subsided, pour off the supernatant liquid; collect the precipitate on a filter and wash it with cold Distilled Water until free from chloride; dry the precipitate, first by imbibition with filtering paper, and then by the application of warmth." *Br.*

The U. S. P. 1880 very properly does not give a process for this alkaloid, as it cannot be made profitably by the pharmacist.

In the U. S. process of 1870 the first step is to obtain a tincture of cevadilla, which is evaporated to the consistence of an extract. This contains the veratrine combined with a vegetable acid, probably gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the natural acid. The magnesia combines with the acids and throws down the veratrine, which is then taken up by alcohol and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the coloring matter and retains the salt of veratrine. This is then decomposed by ammonia, and the precipitated veratrine is slightly washed with cold water to free it from adhering impurities. If much water be employed in the washing, a considerable portion of the veratrine will be lost, in consequence of impure veratrine being in some degree soluble in water. The remaining steps of the British process consist in the purification of the veratrine by forming a hydrochlorate in solution, decolorizing this by animal charcoal, and again precipitating by ammonia.*

The U. S. process of 1870† is essentially that of M. Couërbe. The veratrine obtained by it, though not pure, is sufficiently so for medical use. A drachm of it, in this state, may be pro-

* Mr. James Beatson, manufacturing chemist of the U. S. Naval Laboratory at New York, recommends the following method of preparing veratrine as less complicated and troublesome than the official, and quite satisfactory in its results. Take 73 pounds (avoirdupois) of cevadilla, rub it upon a coarse wire sieve so as to separate the seeds from the capsules, and reduce the former to a coarse powder by a Swift's drug-mill. Pass the capsules also through the mill, separate the finer portion, and mix it with the ground seeds. Moisten the mixture with alcohol, and allow it to stand 12 hours; then introduce it into a displacement apparatus, and pour upon it 30 gallons of alcohol. When a convenient quantity of the liquid has passed, submit it to distillation, and return the distilled alcohol to the displacement apparatus; and proceed in the same way until the cevadilla is thoroughly exhausted. Collect all the alcoholic liquor from the exhausted seeds, and continue the distillation until the tincture has a syrupy consistence. Pour this while hot into eight times its volume of cold water, throw the whole on a calico filter, and wash until the washings cease to indicate the presence of the veratrine. Mix the washings with what first passed through the filter, and add aqua ammoniæ in excess (about 4 pounds). Wash the precipitated veratrine with cold water, and dry it with a very gentle heat. Mr. Beatson obtained by this process eleven and a quarter ounces of veratrine but faintly tinged with coloring matter. (*A. J. P.*, xxvi. 5.)

† *Veratria*, U. S. 1870. "Take of Cevadilla, in moderately fine powder, *twenty-four troyounces;* Alcohol, Sulphuric Acid, Magnesia, Water of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Digest the Cevadilla with eight pints of Alcohol, for four hours, in a distillatory apparatus, with a heat approaching to boiling, and pour off the liquid. To the residue add eight pints more of Alcohol mixed with the portion distilled, and, having digested for an hour, pour off the liquid as before. Digest for a third time with the same quantity of Alcohol, together with the portion last distilled, and again pour off. Press the remains of the Cevadilla, mix and strain the liquids, and, by means of a water-bath, distil off the Alcohol. Boil the residue three or four times in Water acidulated with Sulphuric Acid, mix and strain the liquids, and evaporate to the consistence of syrup. Add Magnesia in slight excess, shake the mixture frequently, then express, and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several times in Alcohol, and strain after each digestion. Distil off the Alcohol from the mixed liquids, boil the residue for fifteen minutes in water mixed with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquid, evaporate with a moderate heat to the consistence of thin syrup, and drop in sufficient Water of Ammonia to precipitate the Veratria. Lastly, wash the alkaloid with Water, and dry it with a gentle heat."

cured from a pound of cevadilla. Meissner, in 1819, applied the term *sabadilline* to an alkaloid extracted by him. Pelletier and Caventou had probably produced the same preparation when they announced the discovery of veratrine in the same year. This substance is the veratrine described as prepared by Couërbe's process. Couërbe, in 1834, announced the discovery of an additional alkaloid, to which he gave Meissner's old name of sabadilline, and Weigelin, in 1871, announced the discovery of a third alkaloid, which he called *sabatrine*. G. Merck, in 1855, obtained veratrine in a crystallized state by solution and separation from strong alcohol.

Wright and Luff (*Journ. Chem. Soc.*, 33, p. 338) have brought order from this confusion by a careful study of the whole subject. They find three alkaloids in sabadilla seeds: *cevadine*, $C_{32}H_{49}NO_9$ (the alkaloid hitherto known as the veratrine of Merck); *veratrine*, $C_{37}H_{53}NO_{11}$; and *cevadilline*, $C_{34}H_{53}NO_8$. Of these, the cevadine (formerly veratrine) forms, when crystallized from alcohol, needles or compact crystals which fuse at 205° C. (401° F.), effloresce rapidly in the air, and become opaque, are insoluble in water, easily soluble in alcohol and ether, and dissolve in warm concentrated hydrochloric acid with a dark violet color, which on boiling becomes intensely red. When heated with alcoholic potash they are decomposed into *methyl-crotonic* (*tiglinic*) *acid* and *cevine*, $C_{27}H_{43}NO_8$. The veratrine of Wright and Luff is obtained from the mother-liquor of the cevadine by extraction with ether. It forms an uncrystallizable resinous mass, fusing at 180° C., but yields crystallized salts. Boiled with caustic soda it is decomposed into *dimethyl-protocatechuic* (*veratric*) *acid* and *verine*, $C_{28}H_{45}NO_8$. Cevadilline remains after the extraction of the veratrine, insoluble in ether. It is also uncrystallizable, nearly insoluble in ether and in boiling benzol, but easily soluble in fusel oil.

Flückiger recognizes only two of these alkaloids, and makes them both of the composition $C_{32}H_{49}NO_9$. The first, which he calls *cevadine*, he states is decomposed by boiling with barium hydrate when in alcoholic solution, and yields products as follows: $C_{32}H_{49}NO_9 + 2H_2O = C_5H_8O_2 + C_{27}H_{45}NO_9$. The first of these products is *methyl-crotonic acid*, and the second is *cevine*. The other alkaloid he calls *veratridine*, and gives its decomposition as follows: $2C_{32}H_{49}NO_9 + 4H_2O = C_9H_{10}O_4 + C_{55}H_{92}N_2O_{16} + 2H_2O$. The first of these products is *dimethyl-protocatechuic acid*, and the second he calls *veratroïn*. (Flückiger, *Pharm. Chem.*, 1888, ii. p. 532.) Merck still terms the cevadine of Wright and Luff veratrine, and prepares it in white crystals of the formula $C_{32}H_{49}NO_9$, fusing at 202° C. Frankforter (*A. J. P.*, 1897, 372) confirms this formula, $C_{32}H_{49}NO_9.H_2O$, but gives to the purified veratrine the melting point from 146°–148° C.

Two acids have also been found in sabadilla,—the *sabadillic* or *cevadic acid* of Pelletier and Caventou, forming needle-like crystals fusing at 20° C., and the *veratric acid* of Merck, which Koerner showed to be dimethyl-protocatechuic acid.

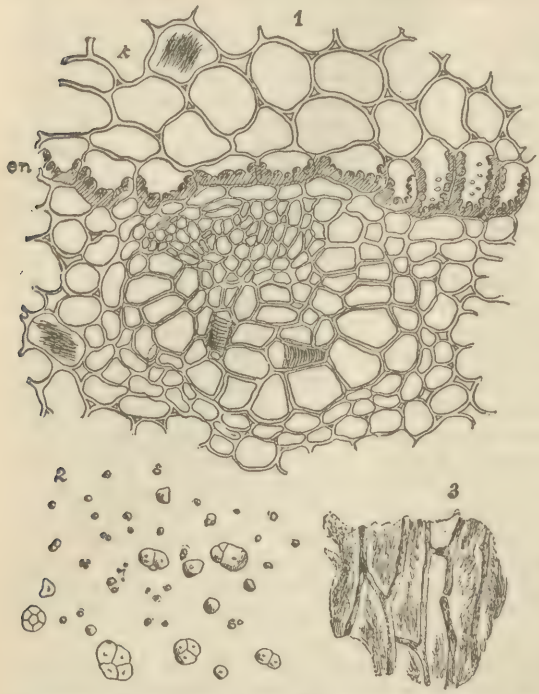
Properties. Veratrine is officially described as "a white or grayish-white, amorphous or semi-crystalline powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane; having an acrid taste, and leaving a sensation of tingling and numbness on the tongue; permanent in the air. Very slightly soluble in cold or hot water; soluble in 3 parts of alcohol at 15° C. (59° F.), and very soluble in boiling alcohol; also soluble in 6 parts of ether, and in 2 parts of chloroform. When heated to 175° C. (347° F.) Veratrine melts, forming a light-brown liquid. Upon ignition, it is consumed, leaving no residue. An alcoholic solution of Veratrine has an alkaline reaction upon litmus paper. With nitric acid, Veratrine forms a yellow solution. On triturating Veratrine with concentrated sulphuric acid, in a glass mortar, the yellow or orange-red solution exhibits, by reflected light, a greenish fluorescence, which becomes more intense upon the addition of more acid, while the liquid is deep red by transmitted light. On heating a small portion of Veratrine with a few C.c. of hydrochloric acid, the liquid will acquire a deep red color." *U. S.* "Pale gray, amorphous; without odor, but, even in the most minute quantity, powerfully irritating the nostrils; strongly and persistently bitter, and intensely acrid; insoluble in *water*, soluble in 3 parts of *alcohol* (90 per cent.) or of *chloroform*, in 6 parts of *ether*, and in diluted acids, leaving slight traces of an insoluble brown resinous matter. It dissolves in *nitric acid*, yielding a yellow solution. Warmed with *hydrochloric acid*, it dissolves with production of a blood-red color lasting several days. Treated with fifty or sixty times its weight of *sulphuric acid*, the mixture turns yellow, subsequently acquires a yellowish-green fluorescence which becomes more distinct on the addition of more acid and slowly changes to bright red, or, if warmed, violet-red. Heated with access of air, Veratrine melts to a yellow liquid, and at length burns away, leaving no appreciable residue (absence of mineral impurity)." *Br.*

Medical Properties and Uses. Veratrine is locally irritant, and exercises a peculiar influence on the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin; but, in general, no decided signs of inflammation are evinced. Upon the denuded cutis, however, veratrine and its salts are powerfully irritating; in the mouth and fauces they produce an almost insupportable sense of acrimony, and snuffed up the nostrils excite violent sneezing. Magendie states that when taken internally in the dose of a quarter of a grain they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Experimenters have observed similar effects. When taken in toxic doses veratrine causes violent vomiting, serous purging, often with intense burning in the mouth and throat, and general muscular weakness. No fatal case of poisoning is on record; but in the experiments of Esche on himself a half-grain of the acetate produced collapse, with a pale, cold, wet skin, pinched features, a rapid, thready, irregular pulse, violent vomiting, and marked muscular tremblings. The phenomena of veratrine poisoning in dogs, rabbits, etc., are failure of muscular power, along with violent muscular twitchings and convulsions, which are often plainly excited by external irritants, severe vomiting, generally but not always accompanied by purging, and disturbance of motion, respiration, and circulation. The pulse is at first, if the dose be not too large, quickened and strengthened, but in a very short time it becomes slower and weaker, and finally very frequent, thready, and irregular. When very large doses are given, the animal often dies at once of a universal paralysis. Veratrine is a powerful muscle-poison, producing a primary stage of muscular hyperexcitability and a condition in which momentary stimuli produce tetanic spasms, and a final stage of rigidity and complete loss of contractility. It is paralyzant to the motor nerves, and probably also to the sensory nerves. Upon the cerebral centres it has little action; its exact influence upon the spinal cord has not been determined. It is a powerful depressant to the respiratory centres, and acts upon the heart-muscle as upon the voluntary muscles. In the earlier stages of its action it slows the pulse and increases the blood-pressure by stimulating the inhibitory cardiac nerves, and probably also by stimulating the muscle-fibres in the heart itself and in the walls of the arterioles.

Veratrine has been chiefly employed in *gout*, *rheumatism*, and *neuralgia*, and has also been praised in *epilepsy* and various other nervous diseases. Its remedial value is very doubtful; and in this country it is very rarely administered. One-thirtieth of a grain (0·002 Gm.) may be given in the form of pill, and repeated every three or four hours till the effects of the medicine are experienced. Some prefer the salts for internal use. Any one of these salts may be prepared by treating veratrine with water acidulated with the acid to perfect neutralization, and then carefully evaporating to dryness. It is employed to some extent as an alterative counter-irritant, locally applied in *chronic swellings*, *stiffening*, and *induration of the joints*, whether from *rheumatism*, from *scrofula*, or simply from *local injuries*, as *sprains*. It may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance in the proportion of from five to twenty grains to the ounce. It is advisable that the alkaloid should be dissolved in a little alcohol or oleic acid before being mixed with the lard. Of the ointment thus prepared, a portion of the size of a filbert may be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. Veratrine may be used in this way to the amount of from two to four grains in the day. Care must be taken to see that the cuticle to which the ointment is applied is sound. When the skin is irritable, smaller quantities than those above mentioned must be used.

VERATRUM VIRIDE. U.S. Veratrum Viride. [American Hellebore.]

(VĔ-RĀ'TRŬM VĬR'Ĭ-DĒ.)



"The rhizome and roots of Veratrum viride, Solander (nat. ord. Liliaceæ)." *U. S.*

Green Hellebore Rhizome; Vératre vert, *Fr.*; Grüner Germer, *G.*

Veratrum viride. Solander in *Art. Hort. Kew.* (1789) 422. Willd. *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.* ii. 121; *B. & T.* 286. The American hellebore,* known also by the names of *Indian poke*, *poke root*, and *swamp hellebore*, has a perennial, thick, fleshy rhizome, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish roots. The stem is annual, round, striated, pubescent, and solid, from three to six

* The specific distinctness of the American plant from the European is very doubtful. Certain Alpine forms of *Veratrum album* are said to resemble exactly the *Veratrum viride*.

feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied by a downy, pointed bract, much longer than its pedicel. The perianth consists of six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The ovary is ovoid, tricarpellary; styles three and persistent. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those below fruitful. The fruit is a three-lobed capsule, three-celled, and containing flat imbricated seeds. This indigenous species of Veratrum inhabits swamps, wet meadows, and the banks of mountain streamlets. It is more abundant northward, but reaches as far south as Georgia. From May to July is the season for flowering. It is doubtful whether the root should be collected in autumn or just before flowering. It should not be kept longer than one year, as it deteriorates by time.

Rhizome of Veratrum album. 1. Transverse section; *k*, raphides; *en*, sheath of the medulla. 2. Starch. 3. The brown parenchymatous tissue of the rind.

Properties. As found in commerce, veratrum viride is usually in small pieces or fragments; but sometimes it comes whole or sliced, so that its characteristic form may be observed. In this condition it is seen to consist of a rhizome one to three inches in length by somewhat less than an inch in thickness where broadest, tapering to a very obtuse or truncated extremity, simple or divided, compact but light, of a dark-brown color externally, and either closely invested with numerous yellowish rootlets often several inches long, or exhibiting marks on the surface whence they have been removed. When sliced, the cut surface is of a dingy-white color. The rootlets are from three to six inches long, about as thick as a large knitting-needle, or somewhat thicker, obviously much shrunk in drying, and marked by numerous close-set indentations, which give them a characteristic appearance. Not unfrequently portions of the dried stem or leafstalks remain attached to the rhizome, which should always be rejected, as they were ascertained by Prof. Procter to be inert. (*A. J. P.*, 1864, p. 99.) The root has a bitter, acrid taste, leaving a permanent impression in the mouth and fauces; it is inodorous, but its powder produces sneezing when snuffed. In sensible properties it closely resembles white hellebore.

The chemical composition of *Veratrum viride* is closely analogous to that of *Veratrum album*, so that a brief review of the chemical history of the two will be given.

Pelletier and Caventou, in 1819, found in the rhizome of *Veratrum album* a substance which they regarded as identical with the veratrine just announced by Meissner as contained in sabadilla seeds. Simon (*Ann. Ch. und Ph.*, 24, p. 214), in 1837, found the alkaloid *jervine* also in *Veratrum album*. Worthington (*A. J. P.*, 1839, p. 89) found an alkaloid in *Veratrum viride* which he considered to be the veratrine then known from other sources. Richardson, in 1857, and Percy, in 1864, confirmed his results. Bullock (*A. J. P.*, 1865, p. 321) shortly after found, on examination of *Veratrum viride*, that while it contained at least two characteristic alkaloids, neither of these was veratrine. The alkaloids noted by Bullock were named in a former edition of this work *viridine* and *veratroidine*. Peugnet (*N. Y. Med. Record*, 1872, p. 120), in 1872,

showed the identity of the first of these with jervine, and this was confirmed by Mitchell (*A. J. P.*, 1874), who also made out a distinct alkaloid in *Veratrum album*, to which he applied the name of *veratralbine*. The veratroidine discovered by Bullock in *Veratrum viride* in 1865 was also found in *Veratrum album* by Tobien in 1877. In a paper published in the *A. J. P.*, April, 1876, Bullock expressed his doubt as to the existence of veratroidine as a distinct alkaloid, considering that it might have been only jervine admixed with resin. Here the matter rested until the elaborate researches of Wright and Luff (*Journ. Chem. Soc.*, 35, pp. 405, 421), who found in *Veratrum album*, *jervine*, $C_{26}H_{43}NO_2 + 2H_2O$, *rubijervine*, $C_{26}H_{43}NO_2$, *pseudojervine*, $C_{29}H_{43}NO_7$, and *veratralbine*, $C_{28}H_{43}NO_5$(?), and also traces of an alkaloid having sternutatory power (possibly *cevadine*). In *Veratrum viride* they found jervine, pseudojervine, cevadine, very little rubijervine, and traces of veratrine and veratralbine. Of these, rubijervine probably agrees with Bullock's veratroidine, although as prepared by Bullock in his earlier experiments it was undoubtedly mixed with resin, as the fusing point given (270° to 275° F.) is much lower than that given by Wright and Luff for their pure crystals, which fused at 236° C. (456·8° F.). Pseudojervine forms crystals very similar to those of jervine, but it fuses at 299° C. (570·2° F.), instead of 231° to 237° C. (447·8° to 458·6° F.). Pehkschen (*A. J. P.*, 1891) finds *jervine* in both the Veratrum species. Obtained by recrystallization from absolute alcohol it forms snow-white crystals of the formula $C_{14}H_{22}NO_2$ (determined by the analysis of the base and of its hydrochlorate and sulphate). It melts at 237·7° C., and is slightly lævogyre. He finds *veratroidine* (rubijervine of Wright and Luff), and gives it the formula $C_{32}H_{53}NO_9$ (determined both by analysis and by molecular weight determination). It melts at 149·2° C., and is optically inactive. He obtained, thirdly, an alkaloid in rhombic crystals, which is probably a purer form of Wright and Luff's *pseudojervine*. Its formula is $C_{29}H_{49}NO_{12}$. It melts at 259·1° C., and is optically inactive. No color reactions could be obtained with this base, but if the slightest quantity of veratroidine or jervine is added, color reactions agreeing with Wright and Luff's pseudojervine are obtained. A very small quantity of a fourth alkaloid (Wright and Luff's veratralbine) was obtained, but not enough to allow of present investigation. Salzberger (*A. J. P.*, 1891) obtained the three bases *jervine*, *rubijervine*, and *pseudojervine*, and the new ones *protoveratrine** and *protoveratridine*, from the rhizome of *Veratrum album*. The first of the new bases has the formula $C_{32}H_{51}NO_{11}$, and crystallizes in microscopic four-sided plates, which melt with charring at 245° to 250° C. The base is exceedingly poisonous and violently sternutatory. It is insoluble in water, benzene, and light petroleum, slightly soluble in chloroform, boiling 96-per-cent. alcohol, and ether. Dilute acids, with the exception of acetic acid, dissolve it. *Protoveratridine*, $C_{26}H_{45}NO_8$, occurs as colorless four-sided plates, which melt at 265° C. It is not poisonous, and does not cause sneezing. It is almost insoluble in the common solvents, but is soluble in dilute acids. Worthington has pointed out the presence of gallic acid and sugar in *Veratrum viride*.

Medical Properties and Uses. When taken in small doses by man, veratrum viride first reduces the force without much lessening the frequency of the pulse, but after a time the pulse-rate falls very much. If any exertion be made during this stage of depression, the slow pulse will be suddenly converted into an exceedingly rapid one. The slow pulse is sometimes moderately full, but is always very soft and compressible; the rapid pulse is exceedingly feeble and small, often thready, and may become imperceptible. Severe nausea and vomiting accompany or follow the reduction of the pulse-rate. That the latter is not due to gastric disturbance is, however, shown by the fact that it often precedes the stomachic symptoms, and may exist without them. During the stage of depression there is always decided muscular weakness and relaxation. After a poisonous dose the symptoms above noted are increased in intensity and become very alarming. A running, almost imperceptible pulse, a cold, clammy skin, intense nausea and incessant attempts at vomiting, or retching, or hiccough, absolute muscular prostration, faintness, vertigo, loss of vision, and semi-unconsciousness, make up the group of extreme symptoms. For full details as to the method in which these symptoms are produced, the reader is referred to H. C. Wood's Treatise on Therapeutics; the allotted space here will allow us only to state that veratrum viride is a powerful spinal and arterial depressant, exerting little or no direct influence upon the cerebral centres; it lowers the pulse-rate by a direct action on the muscle (jervine) and by stimulating the inhibitory nerves (veratroidine); it diminishes

* According to the experiments of Watts Eden (*Arch. f. Exper. Pathol. u. Pharmakol.*, xxix.), protoveratrine is in mammals twenty times more poisonous than crystallized veratrine, paralyzing the vagus, affecting the muscles, at first increasing but soon markedly depressing their excitability and power, and causing death by a centric disturbance of respiration. The alkaloid also affects the heart, and is a powerful local anæsthetic.

the force of the heart-beat by a direct influence on the cardiac muscle (jervine), and produces a general vaso-motor paralysis (jervine) more or less complete according to the size of the dose. By the action especially of the jervine the spinal motor centres are directly depressed. Neither the sensory centres nor the motor or sensory nerves are distinctly affected. Veratrum viride is used in practical medicine to reduce *arterial excitement* and to quiet *spinal spasms*. In *adynamic fevers* it should never be administered; but in the first stage of *frank pneumonia*, or in any disease when true sthenic arterial excitement is to be combated, except it be in *gastritis* or *peritonitis*, it may be employed as a prompt, efficient, and very safe remedy,—very safe, since it is almost incapable of producing death in the robust adult unless used with great recklessness and in repeated doses. In chronic *cardiac diseases* it may be employed in precisely those cases in which digitalis is contra-indicated,—*i.e.*, where there is excessive hypertrophy.

In poisoning, vomiting should be encouraged by large draughts of warm water until the stomach is well washed out. Then the patient should be forced to lie flat upon the back, with the head lower than the feet, and the efforts at vomiting should be restrained. If they cannot be checked, and if the prostration be severe, on no account should the patient be allowed to rise up, but must be made to vomit into a towel. A full dose of laudanum should be given by the rectum, and brandy or whiskey administered by the mouth. Spirits will sometimes be retained only when given undiluted, and in such form they will often quiet the stomach at once. If the stomach refuse alcohol in any shape, the rectum should be made use of. Ammonia may be employed as an adjuvant to alcohol, and in extreme cases should be injected hypodermically, or even into a vein. Strychnine and digitalis should in all severe cases be used hypodermically. The use of external heat is important, and mild flagellations, rubbing with coarse towels, sinapisms, etc., may be used to keep up the external capillary circulation. The drug should always be administered in the form of the *fluid extract*, dose, one to three drops (0·05–0·15 C.c.); or of the *tincture*, dose, three to six drops (0·15–0·30 C.c.), to be given every hour or two, and closely watched. The occurrence of nausea should be the signal for the suspension of the remedy.

VIBURNUM OPULUS. U.S. Viburnum Opulus. [Cramp Bark.]

(VĪ-BŬR′NŲM ŎP′Ū-LŬS.)

"The bark of Viburnum Opulus, Linné (nat. ord. Caprifoliaceæ)." *U. S.*

Besides the official species of this genus, the *V. obovatum*, Walt., a tree shrub growing from Virginia southward, which is botanically very closely allied to *V. prunifolium*, is stated to be used in the Southern United States as an antiperiodic. (*A. J. P.*, 1878.) *V. lantana*, L., a European species, probably shares the therapeutic properties of the official species. *Viburnum opulus*, *cranberry-tree* or *high bush cranberry*, belongs to the section of the genus which has peduncled cymes, light red, acid, roundish drupes, with very flat orbicular not sulcate stones, palmately veined leaves, and scaly winter buds. It is a large bush, reaching the height of ten feet, growing in low grounds from New Brunswick far westward, and southward to Pennsylvania. The leaves are from three- to five-ribbed, strongly three-lobed, broadly wedge shaped or truncate at the base, with the spreading pointed lobes mostly toothed in the sides and entire in the sinuses. The petioles bear two glands at the apex. The *snow-ball tree*, or *Guelder rose*, is a variety in which the whole inflorescence has been turned into a mass of showy sterile flowers.

Properties. The bark is officially described as "in flattish or curved bands, or occasionally in quills, sometimes 30 Cm. long, and from 1 to 1·5 Mm. thick; outer surface ash-gray, marked with scattered somewhat transversely elongated warts of a brownish color, due to abrasion, and more or less marked with blackish dots, and chiefly in a longitudinal direction with black, irregular lines or thin ridges; underneath the easily removed corky layer of a pale brownish or somewhat reddish-brown color; the inner surface dingy white or brownish; fracture tough, the tissue separating in layers; inodorous; taste somewhat astringent and bitter." *U. S.* For a paper giving microscopical examination of Viburnum barks, see *A. J. P.*, 1895, 387, 394.

Medical Action and Uses. This bark has been so little employed in medicine that we are at a loss to understand the reason of its introduction into the Pharmacopœia. Its berries are used to a considerable extent as a substitute for the ordinary cranberry in the making of jellies, and are certainly antiscorbutic. It may be that the bark shares the medical properties of the prunifolium, but this has not been demonstrated.

VIBURNUM PRUNIFOLIUM. U.S. Black Haw.

(VĪ-BŪR'NUM PRŪ-NĮ-FŌ'LĮ-ŬM.)

"The bark of Viburnum prunifolium, Linné (nat. ord. Caprifoliaceæ)." *U. S.*

Viburnum, *U. S.* 1880; Sloe; Stagbush.

V. prunifolium. L. This is a tall, very handsome shrub, which is quite common in the Middle and Southern United States, east of the Mississippi, flowering in May and ripening in the early autumn its ovoid or oblong blackish fruit. It is specifically distinguished by all its flowers being perfect, by its opposite leaves being broadly oval, obtuse at each end, finely and sharply serrate, smooth, shiny above, situated on naked petioles, and by its cymes being sessile.

Properties. The bark is officially described as "in thin pieces or quills, glossy purplish-brown, with scattered warts, and minute black dots; when collected from old wood, grayish-brown; the thin, corky layer easily removed from the green layer; inner surface whitish, smooth; fracture short; inodorous, somewhat astringent and bitter." *U. S.* Mr. Herman Van Allen found the following constituents in viburnum: 1, a brown resinous body, of a very bitter taste, from which it was found impossible to separate the sugar; 2, a greenish-yellow resin or neutral principle of a bitter taste, slightly soluble in water, freely so in alcohol, called by Krämer *viburnin;* 3, valerianic acid; 4, a tannic acid giving a greenish-black color with ferric salts; 5, oxalic acid; 6, citric acid; 7, malic acid; 8, sulphates; 9, calcium, magnesium, potassium, and iron chlorides. (*A. J. P.*, 1880, 443.) As the result of elaborate investigation, T. Shennan (*Royal Coll. Phys. Lab. Rep.*, Edinburgh, vi., 1897) concludes that the *Viburnum prunifolium* contains *viburnic—i. e.*, valerianic—acid, and a non-volatile alkaloid which, however, he failed to obtain in a pure condition.

Medical Properties and Uses. Dr. D. L. Phares, who first called the attention of the profession to this drug, affirms that it is nervine, antispasmodic, astringent, diuretic, and tonic, and is especially useful in the *nervous diseases of pregnancy* and in the prevention of *miscarriage.* Prof. R. L. Payne, Jr., has found that when given in toxic amount to the lower animals viburnum produces progressive muscular weakness, ending in complete paralysis with loss of reflex action, which he believes to be due to an influence upon the motor side of the spinal cord. In warm-blooded animals there is also marked lowering of the arterial pressure, believed by Dr. Payne to be the result of a direct action of the drug upon the heart. The experiments of Payne have in a measure been confirmed by those of T. Shennan, who finds that large amounts of the drug injected directly into the vein of a warm-blooded animal lower blood-pressure; whilst in the frog the extract produces distinct depression of the voluntary muscles and also of the heart. As Shennan took six drachms of the fluid extract within thirty minutes, with no demonstrable effect except a doubtful decrease of the rate and force of the pulse, it is plain that the drug is very feeble. It has, however, come into some vogue as a remedy in the treatment of *dysmenorrhœa, after-pains,* and *ovarian irritation;* it has also received especial commendation in those cases in which there is a persistent disposition to *miscarriage.* In *menorrhagia* it may be given in full doses several days before the coming on and during the continuance of the menstrual hemorrhage. The solid extract (dose, from three to ten grains) does not represent the drug completely, owing to loss of volatile acid; so that the fluid extract should be preferred, in doses of from one to four fluidrachms (4–16 C.c.).

VINUM ALBUM. U.S. White Wine.

(VĪ'NUM ĂL'BUM.)

"An alcoholic liquid, made by fermenting the juice of fresh grapes, the fruit of Vitis vinifera (nat. ord. Vitaceæ), freed from seeds, stems, and skins. When White Wine is prescribed without further specification, it is recommended that a dry White Wine of domestic production (such as California Riesling, Ohio Catawba, etc.) be employed. White Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place." *U. S.*

VINUM RUBRUM. U.S. Red Wine.

(VĪ'NUM RŬ'BRUM.)

"An alcoholic liquid, made by fermenting the juice of fresh colored grapes, the fruit of Vitis vinifera (nat. ord. Vitaceæ), in presence of their skins. When Red Wine is prescribed without further specification, it is recommended that a dry Red Wine of domestic production (such as a native Claret, Burgundy, etc.) be employed. Red Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place." *U. S.*

Wine is the fermented juice of the grape, the fruit of the *Vitis vinifera* of botanists. The juice of sweet grapes consists of a considerable quantity of grape sugar, certain nitrogenized principles, which act as ferments when the proper conditions are developed, and a small portion of extractive, tannic acid, potassium bitartrate, calcium tartrate, common salt, and potassium sulphate, the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with the tartaric, called *racemic acid*. (See page 105.) Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine.

Owing to the growing excellence in quality of American wines, the Committee of Revision of the U. S. P. 1880 decided to abandon the former titles *Vinum Xericum* and *Vinum Portense*, to adopt the old titles *Vinum Album* and *Vinum Rubrum*, and to permit any wine to be used, whether American or foreign, provided it complies with the requirements of alcoholic strength and purity. The British Pharmacopœia 1898 makes Vinum Xericum the only official unmedicated wine, defining it simply as "a Spanish wine," but providing that it shall contain not less than 16 per cent. of alcohol by volume.

Preparation. The juice expressed from the ripe grapes by various methods runs into vats and constitutes the "*must*." The temperature of the air being about 15·5° C. (60° F.), fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the mean time, the must becomes sensibly warmer, and emits a large quantity of carbonic acid, which causes the more solid parts to be thrown to the surface in a mass of froth having a hemispherical shape called the *head*. The liquor from being sweet becomes vinous, owing to the conversion of the grape sugar into alcohol. After a while the fermentation slackens, when it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste and become perfectly clear, the wine is considered formed, and is racked off into casks. But even at this stage of the process the fermentation continues for several months longer. During the whole of this period a frothy matter is formed, which for the first few days collects round the bung, but afterwards precipitates along with coloring matter and tartar, forming a deposit which constitutes the wine-lees.*

Division and Nomenclature. Wines, according to their color, are divided into the red and the white, and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their skins and seeds, or what is collectively called the *marc; white wines*, from white grapes, or from the juice of black grapes fermented apart from the marc. The coloring matter of the grape is almost insoluble in water, and hence the juice of the red grape is nearly colorless, and will produce a white wine if fermented alone; but when fermented with the presence of the grape the alcohol generated dissolves the coloring matter, which is soluble in that liquid, and thus the wine becomes red. The other qualities of wines depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must, as a fermentable liquid, are water, sugar, and a ferment. The exact composition of the must is shown by the following analysis of must obtained from different sources and ranging through a number of years:

	Sp. Gr.	Water, Per Cent.	Nitrogenous Material.	Sugar.	Acid.	Other Non-nitrogenous Material.	Ash.
Minimum	1·0690	51·53	0·11	12·89	0·20	1·68	0·20
Maximum	1·2075	82·10	0·57	35·45	1·18	11·62	0·63
Mean	1·1024	74·49	0·28	19·71	0·64	4·48	0·40

(König's *Nahrungs- und Genussmittel*, vol. ii. p. 436.)

* In certain parts of France the wine-makers are in the habit, during the fermentation of the wines upon the marc, of adding plaster of Paris, under the impression that it improves the color and insures the stability of the wines. The process is called by the French *plâtrage*. It has the drawback of increasing the percentage of potassium sulphate notably, and its practice is now controlled by law in France. Other methods of treatment are the addition of dicalcium phosphate, known as *phosphotage*, and neutralizing the excess of acidity in the must by the addition of marble-dust, known as *chaptalization*. The addition of sugar and water to the must is called *gallization*, and the addition of glycerin to the finished wine is known as *schellization*. For fuller particulars, see Sadtler's *Industrial Chemistry*, 2d ed., p. 205.

If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less, and the redundancy of sugar proportionately greater, and a sweet wine will be formed. It is stated by M. G. Fleury that levulose undergoes the vinous fermentation much less readily than glucose, and that the sugar of sweet wines is chiefly levulose. Whether a grape yields a sweet or a dry wine seems, then, to depend, to some extent, upon the character of its sugar. (*Journ. de Pharm.*, 4e sér., viii. p. 323.) When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong-bodied and sound, without marked sweetness or acidity, and of the kind called *dry*. A small proportion of sugar can give rise only to a small proportion of alcohol, and consequently the less saccharine grapes will generate a comparatively weak or *light wine*, which will be sound and stable in its constitution in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become sharp. In case the wine is bottled before the fermentation is fully completed, the process will go on slowly in the bottles, and the carbonic acid generated, not having vent, will impregnate the wine and render it effervescing and *sparkling*. The *rough* or *astringent* wines owe their flavor to a portion of tannic acid derived from the marc of the grape; and the *acidulous* wines to the presence of carbonic acid, or of an unusual proportion of tartar. Several of the above qualities often coexist. Thus, a wine may be spirituous and rough, sweet and rough, light and sparkling, etc. Wines are made in many countries, and are known in commerce by various names, according to their source. Thus, *Portugal* produces Port and Lisbon; *Spain*, Sherry, San Lucar, Malaga, and Tent; *France*, Champagne, Burgundy, Hermitage, Vin de Grave, Sauterne, and Claret; *Germany*, Hock and Moselle; *Hungary*, Tokay; *Sicily*, Marsala or Sicily Madeira, and Lisa; the *Cape of Good Hope*, Constantia; *Madeira* and *the Canaries*, Madeira and Teneriffe.

In the United States the first attempt to manufacture wine, on an extended scale, was made towards the close of the last century, at Spring Mill, near Philadelphia, by Peter Legaux, agent of the Pennsylvania Vine Company, and proved unsuccessful. The native grape found most suitable by the Company, after the foreign had failed on account of the climate, was the *Schuylkill muscatel grape*. The next attempt was made by the Swiss at Vevay, Indiana, with the Schuylkill grape, and was partially successful, a rough red wine being manufactured which met with a ready sale in the neighboring States. In a few years the manufacture of this wine languished, foreign wines superseding it. The foreign grape, after numerous trials, not succeeding as a wine grape, investigations were undertaken to determine the adaptation of our various native grapes for making wine. Among these the *Catawba grape*, a native of North Carolina, introduced to public notice by Major Adlum, of Washington City, about the year 1825, has been largely cultivated in Southern Ohio as a wine grape. The chief objection to it is its liability to the rot. Within a few years various other varieties of grape have come into vogue, and native wines are constantly improving in quality. The climate of Texas is peculiarly favorable to the growth of the grape-vine. The *El Paso grape* is found in the vicinity of the falls of the Rio Grande; and the *great mustang* grows luxuriantly in every part of the State, and yields a superior red wine. California produces an immense amount of wine, which is now coming into general use. Considering its advantages of soil and climate, there is good reason to believe that it may at no very distant time rank among the most productive wine regions of the globe. According to the report of the State Viticultural Commission, the California product in 1890 was 18,000,000 gallons; in 1891, 20,000,000; in 1892, 10,000,000; in 1893, 20,000,000.* The smallness of the amount in 1892 was due largely to the frosts in Napa

* There can be no doubt that the California wines are steadily advancing in quality, and that many of them now rival the European wines of high class. At the late French Exposition, a California wine made from the Carbenet Sauvignon grape of the Château-Lafitte type received the highest award for excellence over all other wines offered in competition, including the finest vintage of France; whilst the second award for brandies was also given to a California product. Mr. J. De Barth Shorb, late President of the California State Viticultural Commission, has informed us, as the results of numerous analyses made under the auspices of the Commission, that the California red wines or clarets average from 10 to 14 per cent. of alcohol, the white wines 8 to 12 per cent., the ports 18 to 22 per cent., the sherries 17 per cent. The grapes of which these wines are made are not native to California, as is often thought, but are the offspring of cuttings originally introduced from France, Germany, Spain, and Italy. The so-called "Mission grape," of California, is evidently of Spanish origin, having been brought over by the Catholic missionaries in the early history of the country. It varies so much in different localities that it probably comes from various original stocks. Mr. Shorb states that whilst there are really some hundreds of varieties of grapes recog-

and Sonoma counties, and to other temporary causes. Besides these wines, about 2,000,000 gallons of brandy are produced yearly. The average annual production of wine in Europe for the last decade is given as follows: France, 681,181,000 gallons; Italy, 630,000,000; Spain, 563,500,000; Austria-Hungary, 144,200,000; Germany, 83,250,000; Portugal, 78,750,000; Russia, 72,300,000; Servia, 60,750,000; Bulgaria, 56,250,000; Turkey, 45,000,000; Roumania, 40,500,000; Greece, 31,550,000; Switzerland, 22,500,000.

The French wine vintage for 1893 was exceptionally large, amounting to 1,125,000,000 gallons, or nearly double the average of recent years.

Properties. Wine, considered as the name of a class, may be characterized as a spirituous liquid, resulting from the fermentation of a fruit juice, or, in its more restricted use, of a grape juice, and containing coloring matter, and other substances, either combined or intimately blended with the spirit. It always contains a small proportion of aldehyde. All its other qualities vary with the nature of each particular wine. The principal varieties of foreign wines are briefly characterized below. *American* wines are classed as Sherries, Ports, Dry Red, Dry White, Champagnes, Sweet Catawbas, and special brands.

Sherry (Vinum Xericum, Br. 1898, U. S. 1870) is of a deep amber color, and when good possesses a dry aromatic flavor and fragrance, with very little acidity. It is officially defined as "a Spanish wine," and described as "a pale yellowish-brown liquid containing not less than 16 per cent. of ethyl hydroxide by volume." *Br.* It is prepared in the vicinity of Xeres, in Spain, whence its English name *sherry*. This wine is supposed to have been the *sack* of Shakespeare, so called from the word *sec* (dry). Mr. Henry Long has found about a grain of sulphuric acid in an ounce and a half of sherry wine, and supposes it to be free; but in the light of the experiments of MM. Bussy and Buignet it is, we think, more likely to be in the state of potassium bisulphate, resulting from the reaction between potassium bitartrate and calcium sulphate used in preparing the wine. (*P. J. Tr.*, 1867, 732.)

Port (Vinum Portense, U. S. P. 1870) is of a deep purple color, and in its new state is a rough, strong, and moderately sweet wine. When kept a certain time in bottles, it deposits a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavor, and retains its strength. If too long kept, it deposits the whole of its astringent and coloring matter, and becomes deteriorated. Considerable quantities of brandy are usually added to it, which causes its heating quality on the palate. It is one of the strongest wines in common use. According to Dr. Muspratt, of Liverpool, the alcohol in genuine port never exceeds 19 per cent. (*Med. Times and Gaz.*, 1856, p. 355.)

Madeira was the strongest of the white wines formerly in use. It was somewhat acid, and, when of proper age and in good condition, had a rich, nutty, aromatic flavor. It rarely occurs in the market, however, and is of very variable quality, on account of the adulterations and admixtures to which it is subjected after importation.

Teneriffe is a white wine, of a somewhat acid taste, and, when of good quality, of a fine aromatic flavor. Its average strength is about the same as that of sherry. It is made from the same grape as madeira, to which it bears a close resemblance.

Claret, called in France *vin de Bordeaux*, from its being produced near that city, in the district of Médoc, is a red wine, and from its moderate strength is ranked as a light wine. It has a deep purple color, and, when good, a delicate taste, in which the vinous flavor is blended with some acidity and astringency. The most esteemed kinds are the clarets called *Château-Margaux*, *Château-Lafitte*, and *Château-Latour*. Another celebrated variety is the *Château-Haut-Brion* of the Pays de Grave. Claret is the French wine most extensively consumed in the United States.

Pharmacopœial Requirements. The U. S. Pharmacopœia of 1890 does not recognize any special variety of wine, but only the general classes of white and red. (See page 1451.) In

nized by the viticulturists of California, the following are most esteemed. All are foreign grapes except the Lenoir, an American grape, which has been introduced into France, where it is known as Le Jacque:

Red Wines, Clarets.	White Wines, Hocks.	Ports and Sherries.	Brandies.
Carbenet Sauvignon.	Sauvignon Vert.	Old Mission.	Folle Blanche (Cognac grape).
Burgundy Varieties.	Riesling.	Trousseau.	"West's Prolific" (and numerous other hybrids).
Carignan.	Golden Chasselas.	Charbonneau	
Mataro.	Bergher.	Black Burgundy.	All the white varieties.
Grenache.		Pedro Ximenes.	
Zinfandel.			
Black Malvoisie.			
Lenoir.			

For *raisins*: Muscat of Alexandria and Gordo Blanco.

selecting wines for pharmaceutical purposes the apothecary should see that it conforms to the following description and tests of the Pharmacopœia. *White Wine* is a "pale amber-colored or straw-colored liquid, having a pleasant odor free from yeastiness, and a fruity, agreeable, slightly spirituous taste, without excessive sweetness or acidity. The specific gravity, at 15·6° C. (60° F.), should not be less than 0·990, nor more than 1·010. If a portion of White Wine be evaporated, the residue, when dried during twelve hours on a water-bath, should not amount to less than 1·5 nor more than 3 per cent. To neutralize 50 C.c. of White Wine should require not less than 3 nor more than 5·2 C.c. of potassium hydrate normal volumetric solution (limit of *free acid*), phenolphtalein being used as indicator. If 10 C.c. of White Wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride test-solution, only a faint, greenish-brown color may make its appearance (absence of more than traces of *tannic acid*). Tested by the following method, White Wine should be found to contain not less than 10 nor more than 14 per cent., by weight (equivalent to 12·4 to 17·3 per cent. by volume), of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the White Wine carefully measured at the temperature of 15·6° C. (60° F.), evaporate the Wine in a tared capsule to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15·6° C. (60° F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1·0000 corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the Wine under examination, the corresponding percentage being ascertained by referring to the alcoholometric tables." *U. S.* (See PART III.)* "Pale yellowish-brown, containing not less than 16 per cent. of ethyl hydroxide by volume. When a mixture of 50 cubic centimetres of this wine and 50 cubic centimetres of *water*, acidulated with 5 cubic centimetres of the *volumetric solution of sulphuric acid*, is distilled, the distillate, after rejection of the first 10 cubic centimetres, shaken with *ether*, the ethereal liquid separated and its ether removed by evaporation, the residue should not yield a violet coloration when mixed with *test-solution of ferric chloride* (absence of salicylic acid)." *Br. Red Wine* is "a deep red liquid, having a pleasant odor free from yeastiness, and a fruity, moderately astringent, pleasant, and slightly acidulous taste, without excessive sweetness or acidity. The specific gravity, at 15·6° C. (60° F.), should not be less than 0·989, nor more than 1·010. If a portion of Red Wine be evaporated, the residue, when dried during twelve hours on a water-bath, should not amount to less than 1·6 per cent., nor more than 3·5 per cent. To neutralize 50 C.c. of Red Wine should require not less than 3 nor more than 5·2 C.c. of potassium hydrate normal test-solution (limit of *free acid*), eosin or fluorescein being used as indicator. If 10 C.c. of Red Wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride volumetric solution, the liquid should acquire a brownish-green color (due to *tannic acid*). With lead acetate test-solution, Red Wine forms a heavy precipitate which may vary in color from bluish-green to green. If 2 C.c. of Red Wine be mixed, in a test-tube, with 2 drops of chloroform and 4 C.c. of potassium hydrate normal volumetric solution, and the mixture carefully heated, the disagreeable odor of isonitril should not become perceptible (absence of *various aniline colors*). If 50 C.c. of Red Wine be treated with a slight excess of ammonia water, the liquid should acquire a green or brownish-green color; if it be then well shaken with 25 C.c. of ether, the greater portion of the ethereal layer removed, and evaporated in a porcelain capsule with an excess of acetic acid and a few fibres of uncolored silk, the latter should not acquire a crimson or violet color (absence of *fuchsine*). If 25 C.c. of Red Wine, heated to about 45° C. (113° F.), be well agitated with 25 Gm. of manganese dioxide, the liquid filtered off and acidulated with hydrochloric acid, it should not acquire a red color (absence of *sulpho-fuchsine*). Tested by the following method, Red Wine should be found to contain not less than 10 nor more than 14 per cent., by weight (equivalent to 12·4 to 17·3 per cent. by volume), of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the Red Wine accurately measured at the temperature of 15·6° C. (60° F.), evaporate the Wine in a tared capsule to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15·6° C. (60° F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1·0000 corresponds to the specific gravity of an alcohol containing the same percentage of

* This method of ascertaining the amount of alcohol in wine was devised by Mr. H. B. Parsons, and, though subject to a trifling deviation from strict accuracy where the wine contains acetic acid or other volatile constituents, it is far preferable for pharmacists' use to the method of distillation, which requires special apparatus and great care in condensation. The error from the presence of acetic acid could be prevented by neutralizing the wine with a few drops of solution of soda before testing.

absolute alcohol, by weight or volume, as the Wine under examination, the corresponding percentage being ascertained by referring to the alcoholometric tables." *U. S.* (See PART III.)

The official method of ascertaining the alcoholic strength is based upon the following plan of Horsley's. Note the specific gravity of the wine. Then take 5 fluidounces of it, boil it down in a flask to 2 fluidounces, and allow it to cool. All the alcohol is thus driven off. Add to the residuary liquid sufficient distilled water to bring it to the original measure of 5 fluidounces, and ascertain the specific gravity of the mixture. Deduct the excess of its specific gravity over 1·000, which is the specific gravity of distilled water, from the specific gravity of the wine as at first noted, and the difference will be the specific gravity of the alcohol and water in the wine. Then by consulting the tables giving the percentage in alcohol of liquids containing alcohol and water the percentage of alcohol in the wine will be obtained. Thus, suppose the specific gravity of the wine to be 0·997, and that of the liquid, after treatment as directed, 1·020. Then 0·020, the excess of the latter specific gravity over that of water or 1·000, deducted from 0·997, gives 0·977 as the specific gravity of the mixed alcohol and water in the wine, which, by referring to the table in PART III., will be found to indicate a percentage by weight of 15·67 of absolute alcohol.

The intoxicating ingredient in all wines is the alcohol which they contain; and hence their relative strength depends upon the quantity of that substance entering into their composition. The alcohol, however, naturally in wine is so blended with its other constituents as to be in a modified state, which renders it less intoxicating and injurious than the same quantity of alcohol separated by distillation and diluted with water. This is hardly true of the alcohol which is usually added to wines by manufacturers. The following table, taken in part from Girardin's *Chimie appliquée aux Arts industriels*, 5th ed., and in part from König's *Nahrungs- und Genussmittel*, 1880, shows the percentage of alcohol in the best-known European wines:

European Wines.	Percentage of Alcohol by Vol.	Percentage by Weight.	Percentage of Sugar.

Dr. H. Bence Jones has ascertained the acidity of equal bulks of foreign wines, except Teneriffe, expressed in grains of caustic soda. The bulk taken was that of 1000 grains of water at 60° F., and the numbers express the extremes of acid: sherry, 1·95–2·85; port, 2·10–2·55; madeira, 2·70–3·60; claret, 2·55–3·45. The same authority has determined the proportion of sugar to the ounce in sherry, port, and madeira, expressed in grains: sherry, 4–18; port, 16–34; madeira, 6–20. Claret contains no sugar. Assuming that the sugar becomes acid in the

system, the order of acidity of these wines, beginning with the least acid, is claret, sherry, madeira, port. (*Chem. Gaz.*, Jan. 16, 1854, p. 35.)

In view of the important position accorded to American wines at present, the following valuable table, embodying the results of an official inquiry by the late Prof. H. B. Parsons, will be interesting:

Analysis of American Wines. (H. B. Parsons, *Report of Department of Agriculture*, 1880.)

Wines.	Specific Gravity.	Percent. Alcohol by Weight.	Percent. Alcohol by Vol.	Percent. Total Residue.	Percent. Total Ash.	Percent. Glucose.	Percent. Total Acid as Tartaric.	Percent. Fixed Acid as Tartaric.	Percent. Vol. Acid as Acetic.

An examination of this table reveals the fact that wines of great diversity of flavor, acidity, and alcoholic strength are produced in America: there seems to be no difficulty in procuring wines in the market of assured purity and freedom from dangerous adulteration, yet nearly all of them contain alcohol and sugar, which have been added for the purpose of either preserving the wine or improving its taste. Glycerin and glucose are frequently added to wines when they naturally lack body. Additional analyses of American wines, made in the U. S. Government Laboratory in 1884 and 1888, will be found in *Bulletin No. 13*, Part 3, of the U. S. Department of Agriculture.

Dr. Christison considers it a mistake to suppose that wines become stronger by being kept a long time in casks. His experiments appear to prove the reverse. While wine is not rendered more alcoholic by age for some time, its flavor is improved, and its value thus increased. It becomes less acid, partly by the deposition of tartar, and probably also by the reaction between the acids and the alcohol resulting in the production of ether. Most light wines, if not fortified, finally spoil even when well bottled.

Composition. Wines consist mainly of water and alcohol. They contain also volatile oil, œnanthic ether, grape sugar, sometimes glycerin in minute proportion (*Journ. de Pharm.*, Oct. 1859, p. 292), gum,* extractive, coloring matter, tannic, malic, phosphoric, carbonic, and acetic acids, potassium bitartrate (tartar),† and calcium tartrate. The volatile oil has never been isolated, but is supposed to be the cause of the delicate flavor and odor of wine, called the *bouquet*. According to Dr. F. L. Winckler, the bouquet depends upon the presence of a nitrogenous compound of a volatile organic acid with a volatile base, which has a different smell in different wines. *Œnanthic ether* (ethyl acetate, caproate, and pelargonate) was discovered in wine by Pelouze and Liebig. It is obtained towards the end of the distillation of wine on the great scale for making brandy. It forms only about one part in ten thousand of the wine. It is a colorless liquid, having a peculiar vinous odor, and a taste at first slight, but afterwards acrid. It is considered to be identical with *pelargonic ether*, under which head, in PART II., it is more fully described. Œnanthic ether must not be confounded with the substance which gives rise to the bouquet of wine. The other ingredients of wine, just enumerated, are sometimes present and sometimes absent. Thus, sugar is present in sweet wines, tannic acid in rough wines, and carbonic acid in those that effervesce. The different kinds of wine derive their various qualities from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquid; but with almost all the wines of commerce a portion of brandy is mixed, the state of union of which is probably different from that of the natural alcohol of the wine. By the British custom-house regulations, 10 per cent. of brandy may be added to wines after importation; but to good wines not more than 4 or 5 per cent. is added.

Most wines on being kept form deposits, whether in the cask or in bottles. M. L. Pasteur divides these deposits into three kinds. 1. One consists of crystals of potassium bitartrate, of neutral calcium tartrate, or of a mixture of the two salts. This does not adhere to the sides of the vessel, but has sufficient weight to collect in a small bulk on repose. It is productive of little inconvenience physically, and has no injurious chemical effect on the wine. 2. A second deposit, often confounded with the first, but altogether distinct, is formed of the coloring substances which adhere to the sides of the bottles, especially the most dependent. It is owing to the oxidation, through the air, of the soluble coloring matters of the wine, which thus become insoluble. In consequence of its adhesion to the bottle, it allows the wine to be poured off quite clear. Its formation is generally coincident with improvement in the wine, which becomes at the same time lighter-colored, so that after many years the red wines, like port, will be almost as light as madeira. 3. The third kind of deposit is the most troublesome and injurious. It consists of cryptogamic vegetations, which, in the opinion of M. Pasteur, give rise to all the alterations in wines commonly known as maladies. These never adhere to the sides of the bottle, unless confined by the coloring matter, which occurs very rarely. They are little bodies so light that the least movement of the bottle disturbs them and the

* For a paper on the effect of gum upon the determination of the amount of glucose in wine, see *Journ. de Pharm.*, Oct. 1875, p. 274.

† M. Phipson has recognized in some wines, especially a red wine of Meudon and some clarets from Bordeaux, *acid potassium racemate* or *paratartrate*, which he distinguished by the shape of its crystals floating in the wine, and afterwards separated and examined chemically. The crystals are in octagonal tables, partially colored by the red matter of the wine. He considers its presence an evidence of good quality in the wine. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 274, 1866.)

liquid becomes turbid to a considerable extent. In a mere physical point of view, therefore, they are very inconvenient, by interfering with the decanting of the wine; while, acting as ferments, they cause great mischief not only by the change of the principles of the wine, but also by adding to it new products, the direct result of their own action. As most wines are under their influence, the injury they produce in destroying the better qualities of wine is incalculable. (*Journ. de Pharm. et de Chim.*, 4e sér., 1865, ii. 40.) The remedy for this disorder in wines, suggested by M. Pasteur, is to destroy the cryptogams by the aid of heat. All that is necessary is, by means of a water-bath, to expose the wine, in bottles, to a heat of 140° to 160° F. Experience has shown that in this way the wine soon clarifies itself, and keeps well afterwards, with an improved flavor. The process of heating their wines was to some extent employed by the ancients. Appert was the first in modern times to try it; and in fact it is nothing more nor less than his own peculiar process for preserving vegetable liquids. M. de Vergnette-Lamotte also experimented with wines with the same effect; but the theory of the change was first made known by Pasteur. (*Ibid.*, 1866, iii. 118.)

Adulterations. Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Free sulphuric acid in red wines cannot be detected by barium salts; for all wines contain a small quantity of the soluble sulphates. It may be discovered, however, by dropping the suspected red wine on a piece of common glazed paper containing starch. If the wine be pure, the spot, when dry, will be violet blue, and the paper unaltered in texture; but if the wine contain even a thousandth part of sulphuric acid, the paper will be spotted rose-red, and prove brittle and friable when slightly rubbed between the fingers. (*Lassaigne*, *O. Henri*, and *Bayard.*) Formerly the wine-dealers were in the habit of putting litharge into wines that had become acescent. The lead oxide formed with the acetic acid lead acetate, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day this criminal practice is wholly abandoned. The adulteration is readily detected by hydrogen sulphide, which causes a black and flocculent precipitate. Mr. Brande, among the numerous samples of wine of suspected purity which he examined, did not find one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, may sometimes be detected; but it is derived invariably from shot in the bottle, or from some analogous source. Rhenish wines, when acid from the presence of free tartaric or acetic acid, may be restored by the addition of neutral potassium tartrate, which gives rise to the formation of cream of tartar. (*Andrew Ure.*) Spurious mixtures, frequently containing very little of the fermented juice of the grape, and which are sold as particular wines, may not be poisonous; but they are, notwithstanding, highly pernicious in their effects upon the stomach, and always produce mischief and disappointment when depended on as therapeutic agents. The wines most frequently imitated are port and madeira; cider is often the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port, mixed with cider, juice of elderberries, and brandy, and rendered astringent with logwood and alum. According to Stracke, genuine wines do not contain salts of potassa in quantity sufficient to yield a precipitate with platinic chloride. If, therefore, a suspected wine be evaporated to dryness, and the extract, after being washed with alcohol so long as this is colored by it, and then dissolved in water, give a precipitate with platinic chloride, the presence of cider may be suspected. (*Journ. de Pharm.*, Mai, 1862, p. 442.) By most dealers in wine, coloring is employed, made usually of elderberries and alum. The practice of coloring wines is very reprehensible. In France coloring is openly sold with impunity, and extensively employed, although the wine-dealer who uses it is liable to fine and imprisonment.*

The weaker wines often spoil by keeping. In this case they are apt to dissolve any tartar that may have been deposited, and have been found to contain propionic acid. The result is

* *The Detection of Coloring Matter in Wine.* Alum may be detected in red wine by boiling it for a few minutes. If alum be present, even in $\frac{1}{3000}$ part, the wine gradually becomes turbid, and furnishes a flocculent precipitate; while a pure red wine is not rendered turbid, even by long boiling. (*J. L. Lassaigne.*) M. Lapeyrère states (*Journ. de Pharm.*, 4e sér., xi. 291) that logwood may be detected by means of bibulous paper which has been saturated with a neutral copper acetate: a strip of this, if dipped for a moment into natural wine, takes a gray or grayish rose color, but if logwood be present the tint will be a violaceous blue. M. de Cherville dissolves a piece of potash in the wine; if no sediment appear, and the wine become greenish, it is uncolored; if a precipitate fall, it has been colored: a violet sediment indicates elder or mulberries; red, beet root or Pernambuco wood; violet red, logwood; yellow, "phytolac" berries; violet blue, privet berries; pale violet, sunflower. (*Phila. Med. Times*, iv. 639.) A. Dupré recommends that a small cube of jelly (prepared by dissolving 5 grammes of gelatin in 100 C.c. of warm water, and allowing to cool) be placed in the wine. After from 24 to 48 hours the jelly is removed and washed. If the coloring matter be artificial, it will have penetrated the whole cube; if it be natural, only the surface. *Nessler's reagent for wine* consists of 7 parts of alum and 10 parts of sodium acetate in 100 parts of water. Natural-colored wines are not affected by this; artificial colors are altered to a dingy blue. (*Proc. A. P. A.*, xxvii. 213.)

ascribed by M. Nicklés to a fermentative decomposition of the tartar. Of course in this state the wine contains potassa, and would not respond favorably to the test of platinic chloride before given. (*Journ. de Pharm.*, Août, 1862, p. 90.) Lactic acid is one of the products of the changes which take place in the spontaneous deterioration of wine; and M. Balard has succeeded in discovering the peculiar lactic acid ferment in spoiled wines. The appearance of this is preceded by that of globules similar to those of yeast; and after the completion of the lactic acid fermentation, and the commencement of the putrefactive, a throng of vibriones is observable. After the cessation of the vinous fermentation, and during the progress of that of lactic acid, all disengagement of gas ceases.*

Besides the grape, a number of other fruits yield juices susceptible of the vinous fermentation. These are all wines: thus, *cider* is the wine obtained by fermenting the juice of the apple, *perry* is the fermented juice of the pear. Fruit wines may be distinguished from grape wines by the absence in the former of tartaric acid or its salts. The infusion of malt, also, is capable of undergoing this process; and by its fermentation are produced the so-called *malt liquors*,—*i.e.*, *ale*, *porter*, *brown stout*, and *lager beer*. Of these malt liquors lager beer is produced by a slow fermentation at a low temperature; porter, brown stout, and ale, by a rapid fermentation at a high temperature. Porter and brown stout differ from ale in that some of the *malt* out of which they have been made has been partially charred, the torrefaction being carried further in the manufacture of porter, whence the dark color of the latter. Mr. Brande gives the following percentages of alcohol in certain wines and malt liquors: currant wine, 20·55; gooseberry wine, 11·84; orange wine, 11·26; elder wine, 8·79; cider, from 5·21 to 9·87; perry, 7·26; mead, 7·32; Burton ale, 8·88; Edinburgh ale, 6·20; brown stout, 6·80; London porter, 4·20; small beer, 1·28. In the manufacture of these minor wines sugar is often freely added to the liquor before fermentation, and it is evident that in this way has been obtained the excessive alcoholic strength of some of the wines examined by Mr. Brande. Dr. H. Bence Jones gives the following percentages of alcohol in the undernamed liquors: cider, from 5·4 to 7·5; bitter ale, from 6·6 to 12·3; porter, from 6·5 to 7·0; brown stout, from 6·5 to 7·9. According to L. Hoffmann, Burton ale consists, in the 100 parts, of carbonic acid 0·04, absolute alcohol 6·62, extract of malt 14·97, and water 78·37; and pale ale, of carbonic acid 0·07, absolute alcohol 5·57, extract of malt 4·62, and water 89·74. All malt liquors contain, besides water and alcohol, solid substances, which together constitute the so-called extract,—*i.e.*, that which is left behind when the alcohol and water are evaporated. The most important of these solids are dextrin, grape sugar, glycerin, succinic, acetic, lactic, propionic, glucic, and carbonic acids, albumin and albuminous principles, bitter and resinous matters and essential oil from the hop, alkaline and earthy salts. The following table is believed to represent the strength of various beers at the present time (1894), and also to give a fairly accurate idea of the range of the malt liquors of the market:

Kinds.	Percentages.		Contents per Imperial pint.	
	Alcohol.	Extract.	Alcohol. Fluidounces.	Extract. Ounces.
Burton ale (Allsopp's)	8·25	13·32	2·16	2·77
Bass's barley wine	8·41	11·75	2·18	2·42
Edinburgh ale	4·41	3·58	1·12	0·72
Guinness's stout	6·81	6·17	1·74	1·25
Truman, Hanbury & Co.'s porter	4·02	5·12	1·03	1·01
Whitbread's porter	4·28	5·15	1·09	1·03
Hoare's porter	4·18	5·04	1·06	1·03
Perry's ale	3·87	3·65	0·98	0·73
Munich lager	4·70	6·10	1·19	1·22
New York lager	5·86	4·32	1·48	0·88
Munich schenk	3·90	5·70	1·00	1·16
Munich bock	4·60	9·20	1·17	1·90

* *Unfermented Wine.* Under this misnomer the unfermented juice of the grape has had a large sale in America; it cannot properly be called wine, because the alcoholic fermentation is an essential part of wine-making. Grape juice may be preserved by heating, in order to coagulate albuminous principles, filtering, and subsequently heating the bottles containing the filtrate to destroy micro-organisms: this process necessarily affects the flavor. Another method is to add a preservative like salicylic acid or boric acid to the grape juice, and to filter without the use of heat; this preserves the flavor, but is objectionable on account of the presence of the foreign bodies.

Medical Properties and Uses. Wine is consumed in most civilized countries; but in a state of health it is at least useless, if not absolutely pernicious. The degree of mischief which it produces depends on the character of the wine. Thus, the light wines of France are comparatively harmless; while the habitual use of the stronger wines, such as sherry, port, madeira, etc., even though taken in moderation, is always injurious, as having a tendency to induce gout, apoplexy, and other diseases dependent on plethora and over-stimulation. All wines, however, when used habitually in excess, are productive of bad consequences. They weaken the stomach, produce disease of the liver, and give rise to gout, dropsy, apoplexy, tremors, and not unfrequently mania. Nevertheless wine is an important medicine, productive of the best effects in certain diseases. As an article of the Materia Medica, it ranks as a stimulant and antispasmodic. In the convalescence from protracted fever it is frequently the best remedy that can be employed. In certain stages of *fever*, and in extensive *ulceration* and *gangrene*, this remedy, either alone, or conjoined with bark and opium, is often our main dependence. According to Dr. Stokes, of Dublin, the weakness or absence of the first sound of the heart is an indication for the use of wine in *typhus fever*. When given in low *febrile affections*, if it increase the fulness and lessen the frequency of the pulse, mitigate delirium, and produce a tendency to sleep, its further use may be deemed proper; but if it render the pulse quicker, augment the heat and thirst, produce restlessness, or increase delirium, it should be immediately laid aside as injurious. In some convulsive diseases, as, for example, *tetanus*, wine, liberally given, has often proved useful.

Wine, when used medicinally, should be good of its kind; for otherwise it will disagree with the stomach and prove detrimental rather than useful. The individual wine selected for internal exhibition must be determined by the nature of the disease and the particular object in view. Sherry, when in good condition, is a fine wine, and, as it contains very little acid, is to be preferred whenever the stomach is delicate or has a tendency to dyspeptic acidity. Port is generally used in cases of *pure debility*, especially when attended with a loose state of the bowels, unaccompanied with inflammation. In such cases it often acts as a powerful tonic as well as stimulant, giving increased activity to all the functions, especially digestion. Claret is much less heating, and is often useful on account of its aperient and diuretic qualities. Champagne is applicable to the sinking stage of *low fevers* with *irritable stomach*, and is often useful in the *debility of the aged*. All the acidulous wines are contra-indicated in the gouty and uric acid diathesis, as they are apt to convert the existing predisposition into disease.

The quantity of wine which may be given with advantage in disease is very variable. In low fevers it may be administered to the extent of a bottle or more in twenty-four hours, either pure, or in the form of *wine whey*. This is made by adding to a pint of boiling milk, removed from the fire, from a gill to half a pint of white wine, straining without pressure to separate the curd, and sweetening the clear whey with loaf-sugar.

VINA MEDICATA. Medicated Wines.

(VĪ'NĄ MĔD-Ị-CĀ'TĄ.)

Vins médicinaux, *Fr.;* Medicinische Weine, *G.*

The advantages of wine as a pharmaceutical menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change, while at the same time it is less stimulant than rectified or proof spirit, from its smaller proportion of alcohol. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition, and even the strongest acquire such a liability from the principles which they extract from vegetable substances: so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them were formerly of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, from wine of proper strength, and should be kept in a cool place.

VINUM ANTIMONII. U. S. (Br.) Wine of Antimony.

(VĪ'NŲM ĂN-TĮ-MŌ'NĮ-Ī.)

Vinum Antimoniale, *Br.;* Antimonial Wine; Vinum Stibiatum, s. Emeticum, *P. G.;* Vin antimonié, Vin stibié, *Fr.;* Brechwein, *G.*

"Antimony and Potassium Tartrate, *four grammes* [or 62 grains]; Boiling Distilled Water,

sixty-five cubic centimeters [or 2 fluidounces, 95 minims]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Alcohol with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of White Wine. Dissolve the Antimony and Potassium Tartrate in the Boiling Distilled Water, and add the solution to the mixture. When the liquid is cold, filter it through paper, and add enough White Wine, through the filter, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Tartarated Antimony, 40 *grains* or 4 grammes; Distilled Water, boiling, 1 *fl. ounce* (Imperial measure) or 44 cubic centimetres; Sherry, *a sufficient quantity*. Dissolve the Tartarated Antimony in the Distilled Water; mix the solution with sufficient Sherry to form *one pint* (Imp. meas.) or eight hundred and seventy-five cubic centimetres of Antimonial Wine." *Br.*

The Br. Ph. 1898 formula contains 2 grains of tartar emetic in the fluidounce, the U. S. preparation slightly less, about 1·8 grains in a fluidounce.

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains potassium bitartrate and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the antimony. Dr. Paris stated that he had seen the decomposition of the tartar emetic so complete that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan adopted in the U. S. Pharmacopœia of first dissolving the antimonial in water and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound wine, which make a permanent solution. To obviate the risk of decomposition, the Dublin College directed water and rectified spirit in about the proportion in which these exist in the wines just mentioned. The only objection to this menstruum is the want of color, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are that it affords the means of administering minute doses of tartar emetic, and that it is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or an expectorant, or as an emetic in infantile cases. When a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine, as an expectorant or a diaphoretic, is from ten to thirty drops (0·6–1·9 C.c.), given frequently; as an emetic for children, from thirty drops to a fluidrachm (1·9–3·75 C.c.), repeated every fifteen minutes till it operates.

VINUM AURANTII. Br. Orange Wine.

(VĪ'NUM ÂU-RĂN'TI-Ī—âw-răn'shę-ī.)

"Wine made by the fermentation of a saccharine solution to which Fresh Bitter-Orange Peel has been added." *Br.*

This is officially described as "a vinous liquid, having a golden sherry color, and a taste and aroma derived from the Bitter-Orange Peel. It contains 10 to 12 per cent. by volume of ethyl hydroxide. It is but slightly acid to *litmus-paper*. When a mixture of 50 cubic centimetres of this Wine and 50 cubic centimetres of *water*, acidulated with 5 cubic centimetres of the *volumetric solution of sulphuric acid*, is distilled, the distillate, after the rejection of the first 10 cubic centimetres, shaken with *ether*, and the ethereal liquid separated and its ether removed by evaporation, the residue should not yield a violet coloration when mixed with *test-solution of ferric chloride* (absence of salicylic acid). It should yield not more than the slightest reactions with the tests for sulphites." *Br.*

This wine is used as a vehicle, and when the feeble, tonic action of orange peel may be desirable.

VINUM COLCHICI RADICIS. U. S. (Br.) Wine of Colchicum Root.

(VĪ'NUM CŎL'ȼHI-CĪ RĄ-DĪ'CĬS.)

Vinum Colchici, *Br.;* Colchicum Wine; Vin de Bulbes de Colchique, *Fr.;* Zeitlosenknollenwein, *G.*

"Colchicum Root, in No. 30 powder, *four hundred grammes* [or 14 ounces av., 48 grains]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a*

sufficient quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Alcohol with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, pack it moderately in a conical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and afterwards enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

"Colchicum Corm, in No. 20 powder, 4 *ounces* (Imperial) or 200 grammes; Sherry, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Macerate as directed for tinctures." *Br.*

The British 1898 colchicum wine is only half the strength of the U. S. preparation. The latter is intended to be a saturated vinous tincture of colchicum. As the colchicum bulb imported into the United States is of variable strength, the only method by which an active preparation can be insured is to employ a large quantity of it in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss; while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. A wine made from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than our official preparation; but we have seldom been disappointed in obtaining the effects of colchicum from the wine prepared according to the directions of the U. S. Pharmacopœia. The dose of the official wine is from ten minims to a fluidrachm (0·6–3·75 C.c.), repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In *gout* it is frequently given in connection with magnesia and its sulphate; and in *neuralgic cases* we have found much advantage from combining it with the solution of morphine sulphate, especially when it has been desired to give it a direction rather to the skin than to the bowels. It has been employed externally with asserted advantage in *rheumatism*. In overdoses it may produce fatal effects. Death is said to have occurred in one instance from two drachms and a half (9·3 C.c.) of the wine; but much more would probably in general be requisite to produce this result.

VINUM COLCHICI SEMINIS. U. S. Wine of Colchicum Seed.

(VĪ'NUM CŎL'ØHI-CĪ SĔM'I-NĬS.)

Vinum Colchici, *P. G.;* Vin de Semences de Colchique, *Fr.;* Zeitlosensamenwein, *G.*

"Colchicum Seed, in No. 30 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Alcohol with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. Macerate the powder with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the mixture during seven days, in a closed vessel, with occasional agitation. Then filter through paper, adding, through the filter, first, the remainder of the menstruum, and afterwards enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a saturated tincture. Dr. Williams, who introduced the seeds into use, supposed that their active properties resided in their coating, and that it was, therefore, not advisable to bruise them in preparing the wine or tincture. But this has been shown to be an error by the experiments of Mr. Bonnewyn, who found a larger portion of colchicine in a tincture of the bruised than in a tincture of the unbruised seeds. (See *A. J. P.*, xxvi. 120.) Mr. L. I. Morris has shown, however, that by *digesting* instead of macerating the whole seeds the colchicine can be all extracted. (See *Tinctura Colchici.*) In order that the seeds may be properly comminuted, Prof. Maisch recommends that they be macerated for two or three days in a portion of the wine, before being bruised. (*Ibid.*, xxviii. 514.) It is stated that sometimes this tincture becomes turbid from the development of the yeast fungus in it. (Vulpius, *A. J. P.*, xliv. 212.) The dose is from thirty minims to two fluidrachms (1·9–7·5 C.c.). Two fluidounces (60 C.c.) have proved fatal.

VINUM ERGOTÆ. U. S. Wine of Ergot.

(VĪ'NŬM ĔR'GO-TÆ.)

Vin de Seigle, *Fr.;* Mutterkornwein, *G.*

"Ergot, recently ground, and in No. 30 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces,

390 minims]. Mix the Alcohol with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. Moisten the powder with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of the mixture, pack it moderately in a conical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and afterwards enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

The large proportion of fixed oil in ergot interferes with the solvent action of the menstruum, unless the grains are properly comminuted. They should not be bruised so as to "raise" the oil, but ground in a mill, which cuts them in minute pieces. The use of such ground ergot, and of fortified white wine, will insure a more reliable preparation than that formerly directed, which was a diluted fluid extract. The strength has also been increased from twelve and a half per cent. to fifteen per cent. of active ingredient. The dose of this wine is for a woman *in labor* from two to three fluidrachms (7·5–11·25 C.c.); for other purposes, from one to four fluidrachms (3·75–15 C.c.), to be repeated several times a day, and gradually increased if necessary.

VINUM FERRI. Br. Iron Wine.

(VĪ'NUM FĔR-RĪ.)

Vinum Chalybeatum, s. Martiatum; Vin chalybé, *Fr.;* Eisenwein, Stahlwein, *G.*

"Iron, in wire, 1 *ounce* (Imperial) or 50 grammes; Sherry, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Set aside for thirty days in a closed vessel, the Iron wire being almost, but not quite, immersed in the Sherry, the vessel being frequently shaken, and the stopper occasionally removed; filter." *Br.*

When wine is made to react on metallic iron with presence of air, the metal is oxidized, and then unites with the excess of acid of the potassium bitartrate, which is the characteristic salt of wines. The ferruginous salt, therefore, formed is iron and potassium tartrate, or the tartarated iron of the Br. Pharmacopœia; and this was the old method of preparing the Wine of Iron. But it is obvious that the strength in iron cannot be entirely uniform, as the quantity dissolved must depend on the proportion of the bitartrate in the wine, which is variable, and on various circumstances of the manipulation. In consideration of these objections, it was thought best, in the Br. formula of 1864, to substitute a simple solution in the wine of the iron and potassium tartrate already formed, and to abandon the old tedious formula. But it is obvious that a solution of the ferruginous salt in wine is not exactly the same as the wine of iron prepared with the metal, as it contains the potassium bitartrate unaltered. For this and other reasons, the Br. Pharmacopœia has returned to the old method. The dose of the wine of iron is from one to four fluidrachms (3·75–15 C.c.).

VINUM FERRI AMARUM. U. S. Bitter Wine of Iron.

(VĪ'NUM FĔR'RĪ Ą-MĀ'RUM.)

Vin Quinquina ferrugineux, *Fr.;* Bitter Eisenwein, *G.*

"Soluble Iron and Quinine Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Tincture of Sweet Orange Peel, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Syrup, *three hundred cubic centimeters* [or 10 fluidounces, 70 minims]; White Wine, a *sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Soluble Iron and Quinine Citrate in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of White Wine. Add to this the Tincture of Sweet Orange Peel and the Syrup, and, lastly, enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Set the mixture aside for several days, then filter, and pass enough White Wine through the filter to restore the original volume." *U. S.*

Bitter wine of iron, made official in the U. S. P. 1880, has been very largely used in this country, although the objections to the introduction of elixirs into the Pharmacopœia might be made with equal force to its acceptance. It is a mild ferruginous tonic, a fluidounce representing twenty-two grains of iron and quinine citrate of official strength.* The dose is from two to four fluidrachms (7·5–15 C.c.).

* *Bitter Wine of Iron.* The following formula, in which Calisaya bark and gentian are used, is said by Dr. Chas. L. Mitchell to yield an elegant preparation:

Take of ground Calisaya Bark 192 grains; ground Gentian Root 128 grains; Soluble Ferric Citrate 192 grains; Sherry Wine 13 fluidounces; Brandy 1 fluidounce; Alcohol 1 fluidounce; Oil of Orange 12 minims; Sugar 2 ounces; Solution of Iron Tersulphate 2 fluidounces; Ammonia Water q. s. Dissolve the Oil in the Alcohol and mix with the Sherry Wine and Brandy. Percolate with this the ground drugs, recover 15 fluidounces of tincture by pour-

VINUM FERRI CITRATIS. U. S., Br. Wine of Ferric Citrate.

(VĪ′NUM FĔR′RĪ CĪ-TRĀ′TĬS.)

Wine of Iron Citrate; Vin ferrugineux, *Fr.;* Eisenwein, *G.*

"Iron and Ammonium Citrate, *forty grammes* [or 1 ounce av., 334 grains]; Tincture of Sweet Orange Peel, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Syrup, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; White Wine, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Iron and Ammonium Citrate in *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of White Wine. Add to this Tincture of Sweet Orange Peel, and the Syrup, and, lastly, enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Set the mixture aside for several days, then filter, and pass enough White Wine through the filter to restore the original volume." *U. S.*

"Iron and Ammonium Citrate, 160 *grains* or 18·3 grammes; Orange Wine, *a sufficient quantity*. Dissolve the Iron and Ammonium Citrate in sufficient Orange Wine to form *one pint* (Imperial measure) or one thousand cubic centimetres. Agitate occasionally for three days; filter." *Br.* Dose, from one to four fluidrachms (3·75–15 C.c.).

This chalybeate preparation was made official by the U. S. P. 1880: previous to that time it had varied much in composition, from the lack of an authoritative formula. A fluidrachm (3·75 C.c.), the average dose, contains about two and a quarter grains of the iron salt.

VINUM IPECACUANHÆ. U. S., Br. Wine of Ipecac.

(VĪ′NUM ĬP-Ē-CĂC-Ū-ĂN′HÆ—ĭp-ē-kăk-ū-ăn′ē.)

Ipecacuanha Wine; Vin d'Ipécacuanha, *Fr.;* Brechwurzelwein, *G.*

"Fluid Extract of Ipecac, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; White Wine, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them. Set the mixture aside for a few days, then filter." *U. S.*

"Liquid Extract of Ipecacuanha, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Sherry, 19 *fl. ounces* (Imp. meas.) or 950 cubic centimetres. Mix; set aside for forty-eight hours; filter." *Br.*

The preparations of the two Pharmacopœias are not of the same strength,—the U. S. wine containing in a fluidounce the virtue of about 42 grains, the British of only somewhat more than 20 grains. Wine of ipecac possesses all the medical properties of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. As it is milder, without being less efficacious, than antimonial wine, it is preferable as an emetic. It is also much used as an expectorant and a diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum or other liquid preparation of opium. The dose as an emetic for an adult is a fluidounce (30 C.c.); as an expectorant and a diaphoretic, from ten to thirty minims (0·6–1·9 C.c.). A fluidrachm (3·75 C.c.) may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates.

VINUM OPII. U. S. Wine of Opium.

(VĪ′NUM Ō′PĬ-Ī.)

Sydenham's Laudanum; Tinctura Opii Crocata, *P. G.;* Vin d'Opium composé, *Fr.;* Safranhaltige Opiumtinktur, *G.*

"Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Cassia Cinnamon, in No. 60 powder, *ten grammes* [or 154 grains]; Cloves, in No. 30 powder, *ten grammes* [or 154 grains]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Alcohol with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. To the mixed powders add *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the menstruum, and macerate during seven days, with occa-

ing on water. Dilute the iron solution with twice its bulk of water, and add Ammonia in slight excess. Wash and drain the precipitate thoroughly. Mix this with the tincture, and agitate occasionally until a filtered portion has a light yellow color and does not precipitate with tincture of Ferric Chloride. Filter, dissolve the Ferric Citrate and Sugar, and bring up the measure with a little water to 16 fluidounces; a fluidounce represents 12 grains of Calisaya Bark, 8 grains of Gentian Root, and 12 grains of Ferric Citrate. Dose, from one to three fluidrachms.

sional agitation. Then transfer the mixture to a filter, and, when the liquid has drained off, gradually pass through the filter, first, the remainder of the menstruum, and afterwards enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. If 100 C.c. of Wine of Opium be assayed by the process given under *Tinctura Opii*, it should yield from 1·3 to 1·5 Gm. of crystallized morphine." *U. S.*

Wine of opium now contains the virtues of one grain of powdered opium in about 10 minims. The British wine of opium (1885) contained 22 grains of extract of opium, nearly, in 1 fluidounce, so that each fluidrachm contained about half a grain of morphine.

The wine made according to the directions of the U. S. Pharm. of 1890 is a vinous tincture of opium. The aromatic additions are thought to adapt it to certain states of the stomach or system in which laudanum is found to produce unpleasant effects. On being long kept it deposits insoluble matter, a sample of which M. Bihot, of Malines, has shown to consist mainly of narcotine, with possibly a little codeine, without any discoverable trace of morphine. (*Journ. de Pharm.*, xxx. 200.) Mr. Ware recommended it as a local application to the eye in the latter stages of *ophthalmia*, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of wine of opium is from fifteen to twenty drops (0·9–1·25 C.c.).*

VINUM QUININÆ. Br. Quinine Wine.

(VĪ'NUM QUĪ-NĪ'NÆ.)

Vin de Quinine, *Fr.;* Chininwein, *G.*

"Quinine Hydrochloride, 20 *grains* or 2 grammes; Orange Wine, 1 *pint* (Imperial measure) or 875 cubic centimetres. Dissolve; set aside; filter if necessary." *Br.* The Br. Ph. 1898 replaced quinine sulphate used in the 1885 process by quinine hydrochloride on account of the greater solubility of the latter. Each fluidounce contains one grain of quinine hydrochloride.

VITELLUS. U. S. Yolk of Egg.

(VĪ-TĔL'LUS.)

"The yolk of the egg of Gallus Bankiva, var. domesticus, Temminck (class, Aves; order, Gallinæ)." *U. S.*

The yolk of egg has been made official because of its use in the glycerite of yolk of egg.

XANTHOXYLUM. U. S. Xanthoxylum. [Prickly Ash.]

(XĄN-THŎX'Ȳ-LŬM.)

"The bark of Xanthoxylum americanum, Miller, and of Xanthoxylum Clava-Herculis, Linné (nat. ord. Rutaceæ)." *U. S.*

Toothache Tree, Angelica Tree, Suterberry, Pepper Wood, Tea Ash; Clavalier, Frêne épineux, *Fr.;* Zahnwehholz, *G.*

There has been much confusion in regard to the nomenclature of the prickly ashes. We give in a foot-note the synonyms of the two official species as worked out by Prof. C. S. Sargent.† *Aralia spinosa*, or angelica tree, which grows in the Southern States, is occasionally confounded with *X. Clava-Herculis*, L., in consequence partly of being sometimes called, like the latter, *prickly ash*. Its bark is nearly smooth externally, is beset with slender prickles in transverse rows, and has a taste different from that of *X. Clava-Herculis*, L. Besides the official trees, the bark of an *X. caribæum*, Lamarck, the *satin-wood* of semi-tropical Florida and the West Indies, has appeared in commerce under the name of *yellow Hercules club*, or *yellow-thorn*. This bark is thin, with an odor like that of Angustura bark, a bitter, disagreeable, acrid taste, and a canary-yellow color, which it imparts to the saliva when chewed. It

* *Rousseau's laudanum* is a tincture of opium made with very weak alcohol, according to the following formula: "Take of White Honey *twelve ounces;* Warm Water *three pounds*. Having dissolved the honey, set the solution aside in a warm place; and, as soon as fermentation begins, add of selected opium *four ounces*, previously dissolved in *twelve ounces* of water. Allow the mixture to stand for a month at the temperature of 24° Réaumur (86° F.); then strain, filter, and evaporate to *ten ounces;* finally strain, and add *four ounces and a half* of alcohol of 20° B. Seven drops contain about a grain of opium." (*Pharm. Univ.*, ii. 265.)

† *X. americanum*, Miller, is the Northern prickly ash, *X. Clava-Herculis*, Lamarck (not Linné); *X. fraxinifolium*, Marshall; *X. fraxineum*, Willdenow; *X. mite*, Willdenow; *X. ramiflorum*, Michaux; *X. tricarpum*, Hooker; and *Thylax fraxineum*, Rafinesque.

X. Clava-Herculis, Linné, the Southern prickly ash. *X. fraxinifolium*, Walter (not Marshall); *Fagara fraxinifolia*, Lamarck; *X. carolinianum*, Lamarck; *X. aromaticum*, Willdenow; *X. tricarpum*, Michaux; *Kampmannia fraxinifolia*, *Pseudopetalon glandulosum*, *P. tricarpum*, and *X. catesbianum*, the last four names being used by Rafinesque in his different writings.

would seem, also, that under the name of *prickly yellow-wood*, or *yellow-wood*, or *fustic*, the products of other West Indian Xanthoxylums and allied plants find their way into commerce.

X. americanum, Miller, *Gard. Dict.*, 8th ed., No. 2; Torrey and Gray, *Fl. of N. Am.* i. 214. The northern prickly ash is a shrub from five to twenty-five feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. The capsules are stipitate, oval, punctate, of a greenish-red color, with two valves, and one oval blackish seed. This species of Xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odor, recalling that of oil of lemon.

X. Clava-Herculis, L. *Sp. Pl.* (1753) 270; Chapman (*Flora of the Southern United States*, 2d ed., 66), varies in size from a large bush to a small tree. Its bark is armed with warty prickles, and large prickles occur on the branches and the petioles. The alternate leaves have from seven to nine ovate-lanceolate, crenate-serrulate, unequal-sided leaflets, smooth and shining on the upper surface. It grows on dry soil, westward as far as Western Texas, and perhaps into Mexico, eastward to the Atlantic coast, and northward to Southern Virginia, especially affecting the coast region.

Chemistry. *Xanthoxylum fraxineum*, now known as *X. americanum*, was first investigated by Dr. Edward Staples in 1829, and a crystalline principle extracted, to which he gave the name *xanthoxylin*. It was again examined by J. U. Lloyd in 1876, who obtained the same crystalline principle. Edward T. Moffet (*A. J. P.*, 1886, p. 417) also analyzed *X. fraxineum*, and obtained what he considered to be an alkaloid in yellow crystals, soluble in alcohol and chloroform, insoluble in benzin, ether, and benzene. Meanwhile, G. H. Colton (*A. J. P.*, 1880, p. 191) examined the Southern prickly ash, now known as *X. Clava-Herculis*, and obtained crystals forming tasteless, colorless, silky needles, soluble in alcohol, ether, and chloroform, less soluble in benzene, and insoluble in water. The identity of all these principles was assumed until E. G. Eberhardt (*A. J. P.*, 1890, 231) reinvestigated the *X. carolinianum* (*X. Clava-Herculis*) and obtained a colorless crystalline principle agreeing in solubilities with that obtained by Colton. On analysis it gave figures indicating the formula $C_{20}H_{19}O_6$ or $C_{30}H_{28}O_9$. At the same time he analyzed a sample of Lloyd's crystalline principle from *X. fraxineum* (*X. americanum*, Mill.), which had been preserved in the cabinet of the Philadelphia College of Pharmacy, and found for it the formula $C_{29}H_{27}O_8$. Numerous reactions also indicated that the two principles were different. Thus, Lloyd's crystals dissolve in concentrated sulphuric acid with light red color, and on the addition of an excess of water produce a whitish precipitate which is taken up by chloroform; the crystals from the *X. Clava-Herculis*, L., dissolve in concentrated sulphuric acid with dark red color, and on dilution separate a purplish precipitate, which is not taken up by chloroform. Lloyd's principle melts, moreover, at 129·5° C., while Eberhardt's melts at 119° C. The Caribbean *Xanthoxylum Clava-Herculis* was investigated by J. D. Perrin in 1863, and yielded an alkaloid which he considered to be *berberine*. This had also been described as early as 1826 by Chevallier and Pelletan under the name of *xanthopicrite*. *X. senegalense* (*artar root*) has been analyzed by Giacosa and Soave (*A. J. P.*, 1890, 500), who find a fixed oil, a neutral crystalline substance, melting at 120° C., and two alkaloids. The first of these they call *artarine*, and give to it the formula $C_{20}H_{17}NO_4$ (which makes it agree with *berberine*), or $C_{21}H_{23}NO_4$, in which case they consider that it may be *methylhydroberberine*. The second alkaloid, crystallizing in blood-red needles, they did not analyze.

Properties. Although the bark of the Southern prickly ash was not recognized by the U. S. Pharmacopœia until the revision of 1880, as long ago as 1864 Professor Bridges pointed out that it had entered commerce, and gave the physical characteristics separating it. (*Proc. A. P. A.*) The characteristics of the two barks are very well given in the following official description. "*Xanthoxylum Americanum* (Northern Prickly Ash) is in curved or quilled fragments, about 1 Mm. thick; outer surface brownish-gray, with whitish patches, and minute, black dots, faintly furrowed, with some brown, glossy, straight, two-edged spines, linear at the base, and about 5 Mm. long; inner surface whitish, smooth; fracture short, non-fibrous, green

in the outer and yellowish in the inner layer; inodorous; taste bitterish, very pungent. *Xanthoxylum Clava-Herculis* (Southern Prickly Ash) resembles the preceding, but is about 2 Mm. thick, and is marked by many conical, corky projections, sometimes 2 Cm. high, and by stout, brown spines, rising from a corky base. Xanthoxylum should not be confounded with the bark of *Aralia spinosa* Linné (nat. ord. *Araliaceæ*), which is nearly smooth externally, and beset with slender prickles in transverse rows." *U. S.* The bark is very light, brittle, nearly or quite inodorous, and of a taste which is at first sweetish and lightly aromatic, then bitterish, and ultimately acrid. The acrimony is imparted to boiling water and alcohol, which extract the virtues of the bark.

Medical Properties and Uses. Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereum and guaiac in its remedial action, and is given in the same complaints. As a remedy in *chronic rheumatism*, it enjoys some reputation in this country. The dose of the powder is from ten grains to half a drachm (0·65–1·95 Gm.), to be repeated three or four times a day. A decoction, prepared by boiling an ounce in three pints of water down to a quarter, may be given in the quantity of a pint (473 C.c.), in divided doses, during the twenty-four hours. The bark, used as a masticatory, is a popular remedy for *toothache*. Xanthoxylum is capable of being used as a counter-irritant, and great relief is sometimes afforded in various forms of chronic pelvic disease in women by means of a hot pack, applied to the lower part of the trunk, of two to four ounces of fluid extract of xanthoxylum and an ounce of tincture of cayenne pepper to two quarts of hot water.

ZEA. U. S. Zea. [Corn Silk.]

(ZĒ'Ą.)

"The styles and stigmas of Zea Mays, Linné (nat. ord. Gramineæ)." *U. S.*

The ordinary Indian corn of our fields is too well known to need description. The portion which is used in medicine is that which is commonly known as the "silk" of the "ear," being the elongated styles and stigmas of the female flower. It is officially described as "thread-like; about 15 Cm. long, and 0·5 Mm. broad, yellowish or greenish, soft-silky, finely hairy, and delicately veined longitudinally; inodorous; taste sweetish." *U. S.*

Rademaker and Fischer (*A. J. P.*, 1886, p. 369) determined the presence of 2·25 per cent. of *maizenic acid* in dried corn-silk. It was first described, however, by Dr. Vautier. It is freely soluble in water, alcohol, and ether, but insoluble in benzin. Rademaker and Fischer found, in addition to the acid, fixed oil, resin, chlorophyll, sugar, gum, extractive, albuminoids, phlobaphene, salt, cellulose, and water.

Medical Properties and Uses. Zea has been highly recommended by various surgeons as a mild stimulant diuretic, useful in *acute* and *chronic cystitis*, and in the bladder irritation of *uric acid and phosphatic gravel*. It has also been employed in *gonorrhœa*, and has been affirmed by M. Landreux to be a useful diuretic and even cardiac stimulant in the *dropsy of heart disease*. It has been commonly used in the form of infusion, two ounces to the pint of boiling water, taken almost *ad libitum;* but the fluid extract, dose one to two fluidrachms every two or three hours, is an excellent preparation. A solid aqueous extract would probably represent all the activity of the drug, and may be given in doses of five to ten grains three to six times a day. Maizenic acid has been used in doses of one-eighth of a grain (0·008 Gm.).

ZINCUM. U. S., Br. Zinc.

Zn; 65·1. (ZĬN'CŲM.) Zn; 64·9.

"Metallic Zinc in the form of thin sheets, or in irregular, granulated pieces, or moulded into thin pencils, or in a state of fine powder." *U. S.* "The laminated or granulated metal." *Br.*

Spelter; Spelter, Zinc, *Fr.;* Zink, *G.;* Zinco, *It., Sp.*

Zinc occurs native in two principal states,—as a sulphide, called *blende*, and as a carbonate or silicate, to which two the name of *calamine* is applied indiscriminately. In this country there are two additional ores that are worked for zinc. They both occur at Franklin and Mine Hill, New Jersey, and are characteristic of those localities. They are the native oxide, called *red oxide* or *zincite*, and a mixture of zinc oxide with manganese and iron oxide, known as *franklinite*. Zinc has been detected in the vegetable kingdom in a peculiar violet, *Viola calamina*, growing on the calamine hills of Rhenish Prussia. It is largely produced in Belgium, Germany, and this country, the chief American localities being the southwestern section of Mis-

souri, together with the neighboring counties of Kansas, the New Jersey localities before mentioned, Lehigh County, Pennsylvania, Virginia, and Wisconsin. The metal is extracted generally from blende or calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to condense the volatilized metal. The metal is then melted and run into moulds, and forms *spelter*, or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends, its upper extremity reaching a little more than half-way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below. In the arts zinc is purified sufficiently for commercial purposes without volatilization.

The production of spelter in the United States for the year 1897 was 100,387 short tons, valued at $8,271,889, and for 1898 was 112,334 short tons, valued at $10,267,327. The world's production of zinc for 1897 was 445,650 metric tons, of which the United States furnished 91,071 metric tons. The largest producing countries are Germany and Belgium.

Properties. Zinc has a bluish-white color, a peculiar taste, and a perceptible smell when rubbed. Its texture is laminated, and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 100° C. and 148·8° C. (212° F. and 300° F.) to render it sufficiently malleable to be rolled into sheets. The softness of zinc is peculiar, as is shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence to have it in the divided form it is necessary to melt it, and triturate it at the moment of solidification. Subjected to heat it fuses at 398° C. (773° F.). According to Dr. A. von Riemsdyk, it volatilizes to some extent before fusion at a temperature of 268·3° C. (515° F.). (*A. J. P.*, 1869, p. 424.) At full redness it boils, and in close vessels may be distilled over; but in open vessels it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state or in that of oxide. It forms but one oxide (a monoxide) and but one sulphide. The monoxide is official, and will be described under another head. (See *Zinci Oxidum.*)

The official zinc is described as "a bluish-white metal, showing a crystalline fracture, and having a specific gravity ranging from 6·9 when it is cast, to 7·2 after it is rolled. Soluble in diluted sulphuric or hydrochloric acid with evolution of hydrogen gas. When heated above 100° C. (212° F.), and not above 150° C. (302° F.), the metal becomes malleable and ductile; above 200° C. (392° F.), it becomes sufficiently brittle to be powdered in an iron mortar; at 412° to 415° C. (773·6° to 779° F.), it melts, and at 940° C. (1724° F.) it boils and may be readily distilled. When zinc is dissolved in diluted hydrochloric acid, the hydrogen gas which is evolved should not have any disagreeable odor, nor should it color a strip of paper moistened with lead acetate test-solution (absence of *sulphur*), or with silver nitrate test-solution (absence of *arsenic*, *antimony*, *phosphorus*). The solution should be clear and colorless, and should yield a pure white precipitate with potassium ferrocyanide test-solution, and with ammonium sulphide test-solution. If an equal volume of hydrogen sulphide test-solution be added to the solution, neither color nor turbidity should be perceptible (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). If ammonia water be added to the solution, a white precipitate should form, which should redissolve completely in an excess of the reagent, yielding a clear, colorless solution (absence of more than traces of *iron*, *lead*, *copper*, etc.)." *U. S.*

Zinc of good quality dissolves in dilute sulphuric acid, with the exception of a scanty grayish-black residue. If absolutely pure, it would be wholly dissolved. The solution is colorless, and yields white precipitates with potassium ferrocyanide and ammonium sulphydrate. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess.

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper or carbon, for galvanic combinations. Its solution in dilute sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms *brass*, and, in the form of *sheet zinc*, it is employed to cover the roofs of houses, and for other purposes. It is also applied to the covering of iron, to protect it from oxidation, in the same manner as tin,

forming what is known commercially as *galvanized iron*. A fine powder, known as *zinc dust*, obtained by the condensation of zinc vapor in the distillation of zinc from its ores, is much used in chemical laboratories as a convenient reducing agent in many reactions. Zinc should never be used for culinary vessels, as it is soluble in the weakest acids. Zinc and its oxide are dissolved to a certain extent by water containing common salt, a double zinc and sodium chloride being produced in solution. (*Journ. de Pharm.*, Nov. 1867, p. 397.)

The compounds of zinc are poisonous, but not to the same extent as those of lead. The zinc oxide, used in painting as a substitute for white lead, is said to be capable of producing a colic resembling that caused by lead, and called *zinc colic*. It attacks workmen exposed to the dust of the oxide while engaged in packing it in barrels, and yields to the remedies appropriate to the treatment of lead colic. (See *Chem. Gaz.*, Sept. 16, 1850.) This latter statement, however, is, to say the least, very questionable.

Pharmaceutical Uses. Zinc is never used as a medicine in the metallic state, but is employed in this state to prepare zinc sulphate and zinc chloride, and the Reduced Iron of the Br. Pharmacopœia. In combination it forms a number of important preparations.*

ZINCUM GRANULATUM. Br. 1885. Granulated Zinc.

(ZĬN'CŬM GRĂN-Ū-LĀ'TŬM.)

"Take of Zinc of commerce *one pound*. Heat it in an earthen crucible, and immediately the metal is fused remove the crucible from the fire and pour the fluid in a thin stream into a vessel containing about two gallons of cold water. Drain off the water and dry the granulated zinc." *Br.* 1885.

ZINCI ACETAS. U. S., Br. Zinc Acetate.

$Zn(C_2H_3O_2)_2.2H_2O$; 218·74. (ZĬN'CĪ Ą-CĒ'TĂS.) $Zn(C_2H_3O_2)_2.2H_2O$; 218·9.

"Zinc Acetate should be kept in well-stoppered bottles." *U. S.* "Zinc Acetate, $Zn(C_2H_3O_2)_2,3H_2O$, is prepared by neutralizing acetic acid with zinc carbonate." *Br.*

Zinci Acetícum, *P. G.;* Acetas Zincicus; Acétate de Zinc, *Fr.;* Essigsaures Zinkoxyd, *G.*

In the U. S. process of 1870† the zinc oxide is acted upon directly by the acetic acid. During the evaporation of the solution of the zinc acetate, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. Though not economical, these processes have the recommendation of being easily performed, and of yielding a pure product. In relation to the zinc acetate, see a paper by Mr. Ambrose Smith, *A. J. P.* (vii. 14.).

Properties. Zinc acetate is in "soft, white, six-sided, monoclinic plates, of a pearly lustre, having a faintly acetous odor, and an astringent, metallic taste. Exposed to the air, the salt

* *Zinc Nitrate* is sometimes used as a caustic either in the form of *paste* or in *pencils*. M. Lefort prepares it by dissolving commercial zinc with heat in equal volumes of nitric acid and water, maintaining an excess of zinc, and concentrating until a slight basic precipitate is formed, which carries down any iron present. Boiling water is then added, and, when cool, the solution is filtered, and evaporated at a gentle heat until slight ebullition takes place; if then left to cool, it forms a cake, which should be broken up and drained in a glass funnel. Of the zinc nitrate so prepared, 100 grammes are dissolved in 50 grammes of water, and afterwards incorporated with 50 grammes of wheaten flour. This forms a homogeneous paste, which remains soft, spreads easily over surfaces without afterwards contracting, and does not spread at the edges through absorption of moisture. When made into cylinders, it should not be dried by heat, as it slightly decomposes and becomes yellow and friable; it may be kept dry by placing it in a tin box with some pieces of quicklime, but not in contact with them. (*London Medical Record*, June 18, 1873; *A. J. P.*, Dec. 1873.) Dr. Chas. Rice prepares pencils by pouring fused zinc nitrate into paper cylinders which are made by rolling paper around a lead-pencil and sealing with wax. (See *N. R.*, 1876, p. 44; also *Hydrargyri et Zinci Cyanidum*, PART II.) The mixed *mercury and zinc cyanide* was originally suggested as a practical antiseptic by Prof. Lister, who claimed for it the advantages of being non-volatile, unirritating, insoluble in water, and soluble only in three thousand parts of blood serum; so that it is not easily washed off the gauze by discharge from wounds. Its germicidal value is said to be very slight, but its inhibitory power to be such that a one-twelve-hundredth solution will permanently prevent putrefaction in animal fluids. *Cyanide gauze* may be made actively germicidal by impregnation with a solution of one to four thousand of corrosive sublimate. One great objection to the preparation is the difficulty of making gauze with it. The statements of Lister in regard to the best method of preparing the gauze are devoid of the accuracy essential to pharmaceutical success. His method is by "mixing a pretty strong solution of starch with the double cyanide powder, and adding to this a quantity of ground potassium sulphate. The resultant precipitate is dried, and when used is diffused in water in a trough, at the bottom of which the absorbed gauze is placed in layers; when soaked the gauze is drawn out and dried, or if to be used immediately is folded for a moment or two in a towel. When used the gauze may be wet with the corrosive sublimate solution, one to four thousand." (See *Brit. Med. Journ.*, ii. 1889; also *Annals of Surgery*, Jan. 1891.)

† Take of Commercial Zinc Oxide *two troyounces;* Acetic Acid *eight fluidounces and a half;* Distilled Water *five fluidounces*. Mix the Acid and Water, and digest the Zinc Oxide in the mixture for half an hour, then heat to the boiling point, filter while hot, and set aside to crystallize. Drain the crystals in a funnel, and dry them upon bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother-liquor to one-half, slightly acidulating with acetic acid, and crystallizing." *U. S.* 1870.

gradually effloresces, and loses some of its acid. Soluble, at 15° C. (59° F.), in 2·7 parts of water, and in 36 parts of alcohol; in 1·5 parts of boiling water, and in somewhat less than 3 parts of boiling alcohol. Protracted boiling with water renders the salt less soluble, acid being lost and a basic salt formed. When heated, the salt is partially fused, losing water and acid. At a higher temperature it is decomposed, evolving acetone and other combustible vapors, and leaving a residue of zinc oxide. The aqueous solution reddens litmus paper. In the aqueous solution (1 in 20) of the salt hydrogen sulphide test-solution, as well as ammonium sulphide test solution, produces a pure white precipitate; potassium ferrocyanide test-solution also causes a white precipitate. Potassium hydrate test-solution, or ammonium carbonate test-solution, when added in small quantity, produces a white precipitate, which dissolves upon the addition of an excess of the reagent. The addition of a little ferric chloride test-solution produces a red color. The aqueous solution (1 in 20), acidulated with hydrochloric acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). If the aqueous solution be completely precipitated by hydrogen sulphide test solution (without having been acidulated), the filtrate should, after evaporation, leave no fixed residue (absence of *aluminum*, *iron*, *alkalies*, *alkaline earths*, etc.). The aqueous solution should remain perfectly clear after the addition of either barium chloride test-solution (absence of *sulphate*), or silver nitrate test-solution (absence of *chloride*)." *U. S.*

"In thin translucent and colorless crystalline plates, of a pearly lustre, with a sharp unpleasant taste; soluble in 2·5 parts of *water*. It affords the reactions characteristic of zinc and of acetates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, chlorides, or sulphates." *Br.*

The Br. Pharmacopœia gives in its formula for zinc acetate three molecules of water. Although the U. S. Pharmacopœia of 1880 adopted the formula giving to zinc acetate three molecules of water, Dibbit states that it contains but two molecules. Franchimont has confirmed this, and proved that both of these two molecules are lost at the temperature of 100° C. (212° F.). (*Ber. d. Deutsch. Chem. Ges.*, 1879, p. 11; *A. J. P.*, May, 1879.) The U. S. P. 1890 has adopted this view, and recognizes two molecules. The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant; but if ferric oxide be present it will be left undissolved. Zinc acetate is decomposed by the mineral acids, with the escape of acetous vapors.

Medical Properties. Zinc acetate is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in *ophthalmia*, and as an injection in *gonorrhœa*, after the acute stage in these affections has passed. The strength of the solution usually prescribed is one or two grains to a fluidounce (0·065–0·13 Gm. to 30 C.c.) of distilled water.

ZINCI BROMIDUM. U. S. Zinc Bromide.

$ZnBr_2$; 224·62. (ZĬN'CĪ BRŌ'MĮ-DŬM.) $ZnBr_2$; 224·5.

"Zinc Bromide should be kept in small, glass-stoppered vials." *U. S.*

Bromure de Zinc, *Fr.*; Bromzink, *G.*

Bromide of Zinc may be made either by the direct combination of zinc and bromine, or by dissolving zinc in a solution of hydrobromic acid. Mr. L. Lyons proposes to make this salt by dissolving potassium bromide and crystallized zinc sulphate, each, in the smallest quantity of hot water, and mixing while hot. When the mixture has cooled, twice its bulk of alcohol is added, and the whole filtered through asbestos to separate the potassium sulphate. The filtrate is then evaporated to dryness.

Properties. It is officially described as "a white, granular powder, odorless, and having a sharp, saline, and metallic taste. Very deliquescent. Readily soluble in water and alcohol. When heated to 394° C. (741·2° F.), the salt fuses, and, with careful increase of heat, may be sublimed in the form of needle-shaped prisms. The aqueous solution gives a slightly acid reaction with litmus paper. A 5-per-cent. aqueous solution of the salt yields a pure white precipitate with hydrogen sulphide test-solution, ammonium sulphide test-solution, or potassium ferrocyanide test-solution. Silver nitrate test-solution produces a yellowish-white precipitate insoluble in ammonia water. If a few drops of copper sulphate test-solution be mixed with 5 C.c. of the aqueous solution (1 in 20) of Zinc Bromide, and then some sulphuric acid be carefully poured into the mixture so as to form a separate layer, a deep brownish-red color will appear at the line of contact, and will disappear when the mixture is shaken. If to the aque-

ous solution (1 in 20) a little starch test-solution be added, and then some chlorine water, drop by drop, the liquid should assume a pure yellow color, free from any shade of blue (absence of *iodine*). After acidulation with hydrochloric acid, the aqueous solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). On adding ammonium carbonate test-solution to the aqueous solution of Zinc Bromide, a white precipitate is produced which should completely redissolve in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). If from this solution in ammonium carbonate test-solution all the zinc be precipitated by ammonium sulphide test-solution, the filtrate should leave no fixed residue on evaporation (absence of *alkalies*, *magnesium*, etc.). If 0·3 Gm. of the dry salt be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, it should require 26·7 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to not less than 99·95 per cent. of the pure salt)." *U. S.*

Medical Properties. Zinc bromide is capable in excessive doses of acting as an irritant poison. It has been commended in *epilepsy*, but its value is very problematical. Dose, from one to two grains (0·065–0·13 Gm.).

ZINCI CARBONAS PRÆCIPITATUS. U. S. (Br.) Precipitated Zinc Carbonate.

(ZĬN'CĪ CĂR'BŌ-NĂS PRÆ-CĬP-Ĭ-TĀ'TŬS.)

"Zinc Carbonate or zinc hydroxycarbonate, $ZnCo_3(ZnH_2O_2)_2,H_2O$, is produced by the interaction of zinc sulphate and sodium carbonate." *Br.*

Zinci Carbonas, *Br.*, Zinc Carbonate; Zinci Carbonas Præcipitata, *U. S.* 1870; Carbonate of Zinc; Zincum Carbonicum, Carbonas Zincicus; Carbonate de Zinc, *Fr.*; Kohlensaures Zinkoxyd, *G.*

Calamina, U. S. 1850, was dropped from the U. S. Pharmacopœia in 1860 on account of its impurities, and in the 1880 revision the formula for its substitute was also omitted. In the U. S. formula of 1870* a double decomposition takes place between the salts employed, resulting in the formation of sodium sulphate in solution, and basic zinc carbonate which precipitated. Sodium carbonate is preferable to potassium carbonate for decomposing the sulphate, since the former gives rise to sodium sulphate, which is more easily washed away than the potassium sulphate derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. When a solution of zinc sulphate is precipitated by an excess of acid potassium carbonate, a normal zinc carbonate is obtained. With normal sodium carbonate, on the other hand, taken as a precipitant, a basic salt results.

Properties. It is officially described as "an impalpable, white powder, of somewhat variable chemical composition, without odor or taste. Permanent in the air. Insoluble in water or alcohol; soluble in diluted acids with copious effervescence; also soluble in ammonia water, and in ammonium carbonate test-solution. When strongly heated, the salt loses water and carbon dioxide, and leaves a residue of zinc oxide, which is yellow while hot, but becomes white on cooling. When a small portion of the salt is moistened with a drop of cobaltous nitrate test-solution, and heated before the blowpipe, it will assume a vivid green color. For making tests of identity and purity, add 10 C.c. of diluted sulphuric acid and 10 C.c. of water to 1·25 Gm. of the salt, and, after effervescence has ceased, remove the undissolved excess by filtration. In a portion of the filtrate a pure white precipitate is produced by potassium ferrocyanide test-solution, or by ammonium sulphide test-solution. In another portion of the filtrate, acidulated with hydrochloric acid, no color or turbidity should be produced by the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). Another portion of the filtrate should yield, with ammonium carbonate test-solution, a white precipitate, which should redissolve completely in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). No insoluble residue should be left, if 0·5 Gm. of Zinc Carbonate be dissolved in 10 C.c. of diluted sulphuric acid (absence of *lead*). If 1 Gm. of the salt be placed in a flask with 10 C.c. of boiling water and 2 drops of phenolphtalein test-solution be added, not more than 1 C.c. of oxalic acid decinormal volumetric solution should

* "Take of Sulphate of Zinc, Carbonate of Sodium, each, *twelve troyounces*; Water, *eight pints*. Dissolve the salts separately, with the aid of heat, each in four pints of the Water. Then mix the solutions, and, having stirred the mixture, set it by that the powder may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water until the washings are nearly tasteless, and dry it with a gentle heat." *U. S.* 1870.

be required to discharge the red color (limit of *alkali*)." *U. S.* "A white, tasteless, inodorous powder, insoluble in *water*, entirely soluble in *diluted nitric acid*. It affords the reactions characteristic of zinc and of carbonates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, or ammonium, and only the slightest reactions with the tests for chlorides or sulphates." *Br.* If adulterated with chalk it will be only partly soluble in oxalic acid solution. Precipitated zinc carbonate is often sold under the incorrect name of *flowers of zinc*, a name which properly belongs only to the oxide, as obtained by combustion. When obtained from solutions of zinc sulphate and sodium carbonate it has a variable composition, as different hydrated basic carbonates are formed, according to the temperature used, etc.: the higher the temperature and the larger the quantity of water used, the more basic the carbonate becomes. According to the Br. Pharmacopœia, it consists, as thus prepared, of one mol. of zinc carbonate and two mols. of zinc oxide, with three mols. of water ($ZnCO_3 + 2ZnO + 3H_2O$). Its composition is sometimes stated as $(ZnCO_3)_2 3Zn(HO)_2$; 546·96. The basic character of the salt official in the U. S. P. 1870 is explained by the fact that effervescence of carbonic acid takes place on mixing the solutions. It is employed for the same purposes as prepared calamine, and is gradually superseding the spurious article usually sold under that name. The U. S. P. 1870 ordered a cerate made from it as a substitute for calamine cerate.

ZINCI CHLORIDUM. U. S., Br. Zinc Chloride.

$ZnCl_2$; 135·84. (ZĬN'CĪ ȻHLŌ'RĮ-DŬM.) **$ZnCl_2$; 135·7.**

"Zinc Chloride should be kept in small, glass-stoppered bottles." *U. S.* "Zinc Chloride, $ZnCl_2$, is produced by the interaction of hydrochloric acid and zinc." *Br.*

Butter of Zinc; Zincum Chloratum, *P. G.;* Chloruretum Zincicum; Chlorure de Zinc, *Fr.;* Chlorzink, *G.*

The British Pharmacopœia does not give a detailed process for making this salt; that of the Br. Ph. 1885 follows.

"Take of Granulated Zinc *one pound* [avoirdupois]; Hydrochloric Acid *forty-four fluid-ounces* [Imperial measure]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [av.], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Put the Zinc into a porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Test a few drops of the resulting liquid for iron or lead by adding excess of ammonia and then sulphydrate of ammonium, when a black precipitate will be produced if iron or lead be present.

"In the latter case, filter the remainder of the product into a gallon bottle, and pour in the solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears, and the whole of the iron or lead is thus precipitated. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely-stoppered bottles. If no iron or lead be present, filter and evaporate, etc., at once." *Br.* 1885.

In the U. S. process of 1870 * the zinc chloride is obtained by evaporating the previously formed solution. The British first prepares the zinc chloride in solution, and in order to get rid of the iron uses chlorine, which combines with the iron to form ferric chloride; and, the zinc carbonate being added, the zinc combines with the chlorine to increase the product of zinc chloride, whilst ferric oxide is deposited and carbonic acid is set free. As this preparation is used chiefly as a caustic, it is melted and cast into moulds as the last step in the Br. process. In relation to this chloride, the reader is referred to a paper by Mr. B. J. Crew in *A. J. P.*, 1853. M. Rhighini prepares this chloride by double decomposition between solutions of barium chloride and zinc sulphate. Barium sulphate is precipitated, and zinc chloride remains in solution, from which it is obtained in white flaky crystals by due evaporation.

Properties. It is officially described as "a white, granular powder, or porcelain-like masses, irregular, or moulded into pencils, odorless, of such intensely caustic properties as to

* "Take of Solution of Chloride of Zinc *a convenient quantity*. Evaporate the Solution to dryness in an evaporating dish, fuse the dry mass, pour the liquid on a flat stone, and when it has congealed, break the mass in pieces, and keep the fragments in a well-stopped bottle." *U. S.* 1870.

make tasting dangerous, unless the salt be dissolved in much water, when it has an astringent, metallic taste. Very deliquescent. Soluble in about 0·3 part of water at 15° C. (59° F.), forming a clear solution, which, on protracted boiling, deposits a basic salt; very soluble in alcohol. When heated to 115° C. (239° F.), Zinc Chloride fuses to a clear liquid. At a higher temperature it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide. The aqueous solution reddens blue litmus paper. A 5-per-cent. aqueous solution of the salt yields with potassium ferrocyanide test-solution a pure white precipitate, and with ammonium carbonate test-solution a white precipitate, which redissolves in an excess of the reagent. Silver nitrate test-solution produces a white precipitate insoluble in nitric acid. The aqueous solution (1 in 20) should be clear, or at most only very slightly opalescent; and, if it be mixed with an equal volume of alcohol, a single drop of hydrochloric acid should suffice to render 10 C.c. of the mixture perfectly clear (limit of *oxychloride*). If to the aqueous solution, acidulated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, it should not become colored or turbid (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). If ammonium carbonate test-solution be added to the solution, the precipitate should be of a pure white color, and redissolve completely in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). If from this solution in ammonium carbonate test-solution the zinc be completely precipitated by ammonium sulphide test-solution, the filtrate should leave no fixed residue on evaporation (absence of *alkalies*, *magnesium*, etc.). The aqueous solution should not be rendered turbid by the addition of barium chloride test-solution (absence of *sulphate*). If 0·3 Gm. of dry Zinc Chloride be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, it should require 44·1 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color (corresponding to not less than 99·84 per cent. of the pure salt)." *U. S.* "In colorless opaque rods or tablets, very deliquescent and caustic; almost entirely soluble in *water*, *alcohol* (90 per cent.), and *ether*. It affords the reactions characteristic of zinc and of chlorides. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, or sulphates." *Br.*

When pure, it is wholly soluble in water, alcohol, and ether; but as prepared by the U. S. formula it contains some oxychloride, which is left undissolved by water. According to M. Lassaigne, commercial zinc chloride sometimes contains as much as 12 per cent. of zinc arsenate, which, being insoluble in solution of zinc chloride, will be left undissolved when the chloride is treated with water. By filtration, however, it may be entirely separated. It yields with ammonia and potassa a white precipitate, soluble in those reagents when added in excess. It tends to form basic insoluble compounds, the so-called *oxychlorides*, of which Sorel's mass, $Zn\begin{cases} OH \\ Cl \end{cases}$, is an example. These are used for cements and as a filling for teeth. The potassium and sodium carbonates also throw down white precipitates, which are not dissolved by an excess of the precipitants. Zinc chloride has a strong tendency to combine with organic bases, forming crystallizable compounds, as with strychnine, morphine, quinine, cinchonine, etc., in this respect resembling certain other metallic chlorides, as platinum, palladium, gold, and mercury chlorides. (*Journ. de Pharm.*, 4e sér., iii. 56.) When exposed to heat, zinc chloride first melts and then sublimes. It has been obtained in small deliquescent octahedrons of the formula $ZnCl_2 + H_2O$, by evaporating its hydrochloric acid solution to a syrup, and then adding a little concentrated hydrochloric acid. It consists of one atom of zinc and two of chlorine.*

Medical Properties and Uses. Zinc chloride was introduced into medicine by Dr. Papenguth, of St. Petersburg, and subsequently recommended by Prof. Hancke, of Breslau, and Dr. Canquoin, of Paris. Internally it has been given as an alterative and antispasmodic in *scrofula*, *epilepsy*, *chorea*, and other nervous diseases, but is of little or no value. Its chief use has been as an escharotic in *cancerous affections*. As a caustic it has the advantage of not causing constitutional disorder from absorption. Dr. Canquoin prepares zinc chloride as an escharotic by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride incorporated with two, three, four, and five ounces of flour, fifteen drops of water being added for every ounce of flour, or sufficient to form the paste.† According to the French Codex, *Pâte de*

* For the chemistry of its influence on camphor, see *Chem. News*, xx., 1869, p. 229.

† *Dr. Felix's Caustic Paste* (*Lancet*, vol. ii., 1887) is made according to the following formula: Starch, 37 grammes; Wheat Flour, 112 grammes; Mercuric Chloride, 1 gramme; Dry Zinc Chloride, 110 grammes; pure Iodol, 10 grammes;

*Canquoin** (*Canquoin's Paste*) is prepared by triturating an equal weight of flour with the chloride dissolved in a very little water. It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness and strength of the paste, the length of the application, and the nature of the part acted on. The strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second, to *carcinomatous tumors*, and very painful *cancers* which have not much thickness; and the third, to *cancerous affections* in persons who have a dread of the use of the knife. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, with the aid of an emollient poultice, between the eighth and twelfth days. To destroy thick cancerous tumors having an uneven surface and situated in fleshy parts, Dr. Canquoin uses a caustic formed of one part of zinc chloride, half a part of antimony chloride, and two and a half parts of flour, made into a paste with water. In all cases the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. When the skin is unbroken, it is usual to destroy not merely the cuticle, but the true skin also, by means of acid mercuric nitrate, to the extent to which the chloride is desired to operate. This is applied spread on lint, and the dressing is covered with a portion of cotton wadding, to absorb any discharge and to preserve a uniform temperature. The surrounding skin should be protected from the caustic by a thickly-spread dressing of simple cerate. M. Bonnet has applied the paste of zinc chloride to the treatment of *aneurism*. He has reported the complete cure of one case of *subclavian aneurism* from a penetrating wound by a continued series of applications of the paste. Every two or three days the superficial layers of the slough were removed by a bistoury. At the end of the second month the eschar began to detach itself without any hemorrhage, and the clot came away with the eschar. Zinc chloride has also been used successfully by MM. Bonnet and Gensoul in the treatment of aneurism by anastomosis. (*Med. Times and Gaz.*, July 23, 1853.) Instead of flour, Dr. Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous calcium sulphate in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Mr. Cock, of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action and does not run. It may be prepared as a caustic seton by thickly covering a waxed cotton wick with Dr. Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of M. Ancrénis, of Lyons. A thread is wound spirally round the cylinder to give it firmness. Mr. Calloway, of Guy's Hospital, has employed zinc chloride with considerable success in the treatment of *nævi materni*. He rubs it, at intervals, on the part until the skin becomes slightly discolored. The late Mr. Guthrie used it with advantage for penetrating the hard case of new bone which forms over a sequestrum, in order to expose the latter and permit its convenient extraction.

For internal exhibition, the most convenient form is a solution in the spirit of ether, in the proportion of half an ounce to three fluidounces. Of this from four to eight drops (0·24–0·5 C.c.) may be given twice a day. Dr. Lloyd, of London, has found zinc chloride useful as an injection in the acute stage of *gonorrhœa*, made of the strength of about two grains to three fluidounces of distilled water, and employed once in five or six hours. A solution of one grain to the fluidounce is used by Mr. Critchett, of the Royal Ophthalmic Hospital, London, as a collyrium in *vascular and thickened conjunctiva*, forming a sort of gleet of the eye.

In overdoses, zinc chloride acts as a corrosive poison, producing burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. The antidotes are alkalies, or their carbonates, and, if these be not immediately at hand, soap. Dr. Letheby reports a fatal case of poisoning in a child by this chloride. The form of chloride swallowed was Burnett's disinfecting fluid. (See *Liquor Zinci Chloridi*.) Its local effect was that of a corrosive on the lips, mouth, and fauces. Among the constitutional

Croton Chloral, 10 grammes; Camphor Bromide, 10 grammes; Crystallized Carbolic Acid, 10 grammes; Distilled Water, sufficient to form a stiff homogeneous paste. The hand should be wetted when applying it. The paste is allowed to remain on from six to twenty-four hours, according to the amount of eschar it is desired to form.

* P. Carles states that the official paste is too hygroscopic: he triturates in a mortar 10 grammes of fused zinc chloride with 2 grammes of 60-per-cent. alcohol, and incorporates, with constant trituration, 15 grammes of wheat flour. This mass may be formed into cylinders of suitable size, and when once dry is but little affected by atmospheric humidity. (*L'Union Pharm.*, Avril, p. 100.)

effects were paralysis of the voluntary muscles, coldness of the surface, dilated pupils, and coma.*

ZINCI IODIDUM. U. S. Zinc Iodide.

ZnI_2; 318·16. (ZĬN'CĪ Ī-ŌD'Ĭ-DŬM.) ZnI_2; 318·1.

Iodure de Zinc, *Fr.*; Jodzink, *G.*

This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and, by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of zinc sulphate. It may also be obtained by heating in a flask a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. Thus prepared, it is in the form of white needles. This salt is very liable to spontaneous decomposition. "Zinc Iodide should be kept in small, glass-stoppered bottles." *U. S.*

Properties. The U. S. Pharmacopœia of 1890 describes it as "a white, granular powder, odorless, and having a sharp, saline and metallic taste. Very deliquescent, and liable to absorb oxygen from the air, and to become brown from liberated iodine. Readily soluble in water, alcohol, or ether. When heated to about 446° C. (834·8° F.), the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decomposed and leaves a residue of zinc oxide. The aqueous solution reddens blue litmus paper. A 5-per-cent. aqueous solution of the salt yields a pure white precipitate with potassium ferrocyanide test-solution, or with ammonium sulphide test-solution. With silver nitrate test-solution it yields a pale yellow precipitate, insoluble in ammonia water; with mercuric chloride test-solution a scarlet-red precipitate, soluble in potassium iodide test-solution. The aqueous solution, acidulated with hydrochloric acid, should not be colored or rendered turbid by hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.); nor by barium chloride test-solution (absence of *sulphate*). If ammonium carbonate test-solution be added to the aqueous solution, a pure white precipitate will form, which should redissolve completely in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). If from the solution in ammonium carbonate test-solution all the zinc be precipitated by ammonium sulphide test-solution, the filtrate should leave no fixed residue on evaporation (absence of *alkalies*, *magnesium*, etc.). If 0·5 Gm. of dry Zinc Iodide be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, not more than 31·4 C.c. nor less than 31·0 C.c. of silver nitrate decinormal volumetric solution should be required to produce a permanent red color (31·4 C.c. corresponding to 100 (99·9) per cent., and 31·0 C.c. to 98·62 per cent., of pure Zinc Iodide)." *U. S.*

Medical Properties. Zinc iodide was proposed by Dr. Barlow as an alterative remedy in *chorea*, *scrofula*, and *hysteria* (*Med. Times and Gaz.*, Nov. 1853), but has failed to come into general use. The best form of administration is in *syrup*, to protect it from change. The dose is from one-half to two grains (0·03–0·13 Gm.).† Zinc iodide has been used for many years as an external application. Dr. J. J. Ross, of Scotland, employed a solution containing from ten to thirty grains to the fluidounce of water, with great advantage, in *enlarged tonsils*, applied by means of a piece of sponge tied to a quill. After the use of the solution for some time, he applied the iodide, rendered liquid by deliquescence, by means of a camel's-hair brush. A solution containing from one to two grains (0·065–0·13 Gm.) to the fluidounce (30 C.c.) of water has been used as an astringent injection in *gonorrhœa*. An ointment made with a drachm (3·9 Gm.) of the iodide to an ounce (31·1 Gm.) of lard has been commended by Dr. Ure in the treatment of *tumors*, applied in the quantity of a drachm twice a day.

* *Solution of Zinc Hypochlorite.* This may be prepared by the process of R. F. Fairthorne, as follows. "Take of Chlorinated Lime, 12 troyounces; Zinc Sulphate, 24 troyounces; Water, 12 pints. Dissolve the zinc sulphate in three pints of water. Triturate the chlorinated lime, a little at a time, with portions of the water added slowly, and mix thoroughly with the remainder of the water. Allow it to stand until the lime has subsided. Pour off the clear liquid. Transfer the sediment to a muslin strainer, and allow it to drain until sufficient liquid has passed to measure 8 pints with the decanted portion of the solution. Mix this with the solution of zinc sulphate, and, having set it aside for twelve hours, pour off the clear portion of the liquid and place the remaining portion on a piece of muslin to drain. Mix these liquids, and pour more water on the precipitate, if necessary, so as to make 11 pints and a half of the finished product." (*A. J. P.*, March, 1881.) This solution is recommended as having advantages over solution of chlorinated soda, in not being alkaline, and as combining astringent and antiseptic properties, and thus useful as an ingredient in gargles, injections, or lotions.

† Mr. A. B. Taylor, of Philadelphia, prepares a syrup of zinc iodide by gently heating, in an evaporating dish, *twelve drachms and two scruples* of iodine, and *an ounce* of finely granulated zinc, with *nine fluidounces* of water, until they unite, filtering the solution, while hot, on *a pound* (av.) of sugar, contained in a wide-mouthed bottle holding a little more than a pint, and adding, through the filter, sufficient water to make the whole measure a pint. This syrup is perfectly clear and colorless, is styptic to the taste, and contains a drachm of zinc iodide in each fluidounce. (*A. J. P.*, Jan. 1852, p. 33.) The dose of this syrup is from twenty to fifty drops (1·25–3·12 C.c.), sufficiently diluted with water, three times a day.

ZINCI OXIDUM. U. S., Br. Zinc Oxide.

ZnO; 81·06. (ZĬN'CĪ ŎX'Ĭ-DŬM.) ZnO; 80·9.

"Zinc Oxide, ZnO, may be prepared by exposing zinc carbonate to a dull red heat, or from metallic zinc by combustion." *Br.*

Zincum Oxydatum Purum, *P. G.;* Oxydum Zincicum; Oxyde de Zinc, *Fr.;* Philosophenwolle Zinkblumen, Zinkoxyd, *G.*

The British Pharm. 1885 and the U. S. P. 1870* prepared the zinc oxide from the carbonate already formed. By referring to the article on Precipitated Zinc Carbonate, it will be found that it is obtained in the process from zinc sulphate, by the decomposing influence of sodium carbonate. Other methods of obtaining the zinc carbonate are by the mutual decomposition of the sodium chloride and carbonate and the ammonium sulphate and carbonate; but the official plan is to be preferred. M. Lefort found it to furnish a carbonate which is washed with facility and is convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*Journ. de Pharm.*, 3e sér., xi. 329.) It is, besides, more economical. The zinc carbonate, in whatever way obtained, is exposed to heat to drive off the carbonic acid and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary, a temperature between 280° and 300° C. (536° and 572° F.) being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

Zinc oxide may be obtained by the combustion of the metal; and in this way it was formerly prepared by the Dublin College. Zinc melts at 433° C. (801·4° F.), and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. The late Mr. G. D. Midgely, of London, several years ago, called attention to the production of zinc oxide by combustion, and gave a description of the apparatus by which he was enabled to prepare from one to two hundred-weight of the oxide at one operation. It consisted of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeded. The necessary draught of air was conveyed from the muffle by a tube passing through the top of the furnace and terminating in a vessel of water, in which the portion of oxide carried up by the current was retained. The resulting oxide was freed from particles of metallic zinc by being passed through a sieve. Zinc oxide has been very largely produced from calamine by the so-called "furnace and bag" process, at Bethlehem, Pa., by the Lehigh Zinc Company. The process is as follows. The ore is first ground fine by a stone crusher, and then carefully mixed with coal known as "buckwheat," next in grade to "pea." It is then transferred to the furnaces, of which there are fifty-four, with 1390 feet of grate-surface. Within these the mixed coal and ore are reduced by the direct action of heat and the cold blast upon a furnace-bed having a multiplicity of small holes, each producing the reducing flame of the blow-pipe. The zinc oxide rises, and passes through a huge combustion-flue to a large circular tower, 50 feet high, in which the oxide and ashes separate. The ashes being heavier than the oxide, the velocity of the fans which impel the product forward lifts the oxide to the top, and the ashes drop to the bottom. The oxide is forced onward through a cooling-room, size 80 by 40 feet, and heated to from 400° to 700° F. Thence the oxide is blown through large flues into the "bag" room. This is a large building, devoid of furniture, except bags of muslin, 45 feet long, in which the oxide is deposited. It is now very white, and, after being kiln-dried and bolted, is by heavy pressure reduced in bulk and barrelled, ready for shipment. The production of zinc oxide for pigment purposes has assumed large proportions, amounting in 1897 to 26,262 tons, valued at $1,686,020, and in 1898 to 32,747 tons, valued at $2,226,796.

Properties. The official zinc oxide is "an amorphous, white powder, without odor or taste. It gradually absorbs carbon dioxide from the air. Insoluble in water or alcohol. Soluble, without effervescence, in diluted acids; also in ammonia water, and in ammonium carbonate test-solution. When heated, it assumes a yellow color, which disappears again on cooling. If a small portion of the Oxide be moistened with a drop of cobaltous nitrate test-solution, and heated before the blow-pipe, it will assume a vivid green color. For making tests of identity and purity digest 1 Gm. of Zinc Oxide, during one hour, with occasional agitation, in a mixture of 10 C.c. of diluted sulphuric acid and 10 C.c. of water; then remove the undissolved zinc oxide by filtration. In

* "Take of Precipitated Carbonate of Zinc *twelve troyounces*. Expose it, in a shallow vessel, to a low red heat until the water and carbonic acid are wholly expelled." *U. S.* 1870.

a portion of the filtrate a pure white precipitate is produced by potassium ferrocyanide test-solution, or by ammonium sulphide test-solution. In another portion of the filtrate, acidulated with hydrochloric acid, no color or turbidity should be produced by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). Another portion of the filtrate should yield, with ammonium carbonate test-solution, a pure white precipitate, which should redissolve completely in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). If from this solution in ammonium carbonate test-solution the zinc be completely precipitated by ammonium sulphide test-solution, the filtrate should, on evaporation, leave no fixed residue (absence of *alkalies*, *magnesium*, etc.). In another portion of the filtrate silver nitrate test-solution should not produce a turbidity (absence of *chloride*). If Zinc Oxide be agitated for some time with water, and a drop of phenolphtalein test-solution be added, no red color should appear (absence of *alkaline carbonate*, etc.). If 10 C.c. of diluted sulphuric acid be added to 0·5 Gm. of Zinc Oxide, no effervescence should occur (absence of *carbonate*), and a perfectly clear solution should result (absence of *lead*, *silicate*, etc.). If Zinc Oxide be dissolved in diluted hydrochloric acid, the solution should remain perfectly clear after the addition of barium chloride test-solution (absence of *sulphate*)." *U. S.* "Prepared from the carbonate it is a soft, nearly white, tasteless and inodorous powder, becoming pale yellow when heated; prepared by combustion it is white. It affords the reactions characteristic of zinc. It should be entirely soluble when rubbed, and, if necessary, warmed, with *solution of ammonia* mixed with *strong solution of ammonia* (absence of metallic zinc). It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, carbonates, chlorides, or sulphates." *Br.* As obtained by combustion, it is perfectly white. It dissolves in potassa and soda, but not in their carbonates. Being anhydrous, it is insoluble in ammonia; but the impure oxide found in commerce, being generally hydrated, is soluble in that alkali. At a low white heat it fuses, and at full whiteness sublimes. When prepared by combustion it was formerly called *pompholix*, *nihil album*, *lana philosophica*, and *flowers of zinc*. Prepared by the old official process,—namely, by precipitating zinc sulphate with ammonia,—it contains the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid and precipitating by barium nitrate. Sometimes it is obtained by precipitating zinc chloride with ammonia, in which case the oxide contains subchloride, easily detected by silver nitrate. If it contain white lead or chalk, it will not be entirely soluble in dilute sulphuric acid, but an insoluble lead or calcium sulphate will be left. If iron be present, brownish-red flocks of ferric oxide will remain undissolved when the hydrochloric acid solution of the oxide is treated with ammonia in excess.

The powder sold in commerce as zinc oxide is often very impure. Sometimes the carbonate is substituted for it, showing that the exposure to a red heat has been omitted. In this case the preparation will effervesce with acids. Some samples contain a large proportion of subsulphate, showing that the discarded but productive process of precipitating the solution of zinc sulphate by ammonia has been employed. Again, other samples contain oxychloride. These impure oxides are pointed out by Mr. Redwood, of London, as occurring in the English market, and no doubt are sold in the United States. (See *P. J. Tr.*, 1855, p. 301.) A sample of commercial zinc oxide is noticed in *N. R.*, Aug. 1878, which proved to be powdered gypsum. Unfortunately, a white oxide is preferred by purchasers, though whiteness is generally a sign of impurity: the yellowish-white official oxide should be exclusively used by pharmacists.

Medical Properties and Uses. This oxide is antispasmodic and astringent. It has been given in *chorea*, *epilepsy*, *whooping-cough*, and *gastric* and *intestinal catarrhs*. Externally it is employed as an exsiccant to excoriated surfaces, sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi*.) It has also been used in *gonorrhœa*. (*N. R.*, July, 1874.) The dose is from two to eight grains (0·13–0·52 Gm.) or more, repeated several times a day, and given in the form of pill. As a cosmetic it has the great advantage over the preparations of lead of not being poisonous.

Zinc oxide, prepared by combustion, called commercial zinc oxide, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discolored by hydrogen sulphide. It is stated that it has greater covering power as a color than white lead, 10 parts being equal to 13 of white lead. It is, however, dearer, so that the pure oxide has not replaced white lead. The oxide thus prepared, even though pure, should not be substituted for the official, as it has not the smoothness and freedom from gritty particles possessed by the latter. There is an English preparation known as *Griffith's zinc-white*, or *zincolith*, made by precipitating zinc sulphate by barium sulphide: it is, therefore, a mixture of zinc sulphide

and barium sulphate. If this be roasted in a current of superheated steam the zinc sulphide will be converted into zinc oxide. This process has been patented in Germany by Meissner. (Wagner's *Chem. Technol.*, 11th ed., p. 159.) It has, moreover, the merit of not producing injurious effects on the workmen at all comparable to those caused by white lead. It is, indeed, usually considered innocuous; but a case of chronic poisoning by it has been reported by Prof. Botkin. (*Brit. and For. Med.-Chir. Rev.*, ii., 1873.)

ZINCI PHOSPHIDUM. U. S. Zinc Phosphide.

Zn_3P_2; 257·22. (ZĬN'CĪ PHŎS'PHĮ-DŬM.) Zn_3P_2; 256·7.

Phosphure de Zinc, *Fr.;* Phosphorzink, *G.*

According to Hager, zinc phosphide was first prepared by Marggraf in 1740. It was formerly made by fusing, in a bath of iron filings, 74 parts of pure zinc, and adding gradually, in small pieces, 26 parts of dry phosphorus. This process gives good results only in small quantities (10 to 20 Gm.). A more recent process is to pass vapors of phosphorus in a current of dry hydrogen over fused zinc. The product is a spongy, gray mass, of metallic appearance, containing rhomboidal crystals, and when powdered resembling somewhat reduced iron. The metallic particles of zinc should be separated. Its sp. gr. is 4·72. "Zinc Phosphide should be kept in small, glass-stoppered vials." *U. S.*

Properties. It is thus described in the U. S. Pharmacopœia of 1890. "A gritty powder of a dark gray color, or crystalline fragments of a dark, metallic lustre, and having a faint odor and taste of phosphorus. In contact with the air it slowly emits phosphorous vapor. Insoluble in water or alcohol. Soluble in diluted hydrochloric or sulphuric acid with evolution of hydrogen phosphide. When strongly heated with exclusion of air, it melts, and finally sublimes. When heated it air, it becomes oxidized to zinc phosphate. If 0·5 Gm. of Zinc Phosphide be dissolved in 15 C.c. of diluted hydrochloric acid, heat being applied to expel all of the hydrogen phosphide gas, a clear solution should result, leaving no residue (absence of *insoluble impurities*). A portion of this solution should yield a pure, white precipitate with potassium ferrocyanide test-solution (absence of *iron* or *copper*); or with ammonium sulphide test-solution (absence of *lead* or *copper*). If another portion of this solution be mixed with an equal volume of hydrogen sulphide test-solution, no color or turbidity should appear (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.)." *U. S.* For a method of assay of zinc phosphide, see *N. R.*, June, 1879.

Medical Properties. It has been proved by direct experiment upon animals, as well as by clinical experience, that zinc phosphide affects the system physiologically and therapeutically in exactly the same manner as does phosphorus, and it is now very frequently employed in medicine as a substitute for that element. Theoretically, each grain of the phosphide contains nearly a quarter of a grain of phosphorus. It is asserted in the journals to have been administered in doses of one or even two grains; but of the pure salt such amounts would be extremely dangerous: the commencing dose is one-twentieth of a grain (0·003 Gm.).

ZINCI SULPHAS. U. S., Br. Zinc Sulphate.

$ZnSO_4.7H_2O$; 286·64. (ZĬN'CĪ SŬL'PHĂS.) $ZnSO_4.7H_2O$; 286·9.

"Zinc Sulphate, $ZnSO_4,7H_2O$, is formed by the interaction of diluted sulphuric acid and zinc." *Br.*

Zincum Sulfuricum, *P. G.;* Sulfas Zincicus, Vitriolum Album; Sulfate de Zinc, Vitriol blanc, *Fr.;* Schwefelsaures Zinkoxyd, Weisser Vitriol, Galitzenstein, *G.*

The Pharmacopœias no longer give detailed processes for preparing this salt. The Br. Ph. 1885 process will be found in the foot-note.*

Strong sulphuric acid is very little acted upon by zinc, some hydrogen sulphide being evolved by the reduction of the acid; but when it is *diluted*, water is instantly decomposed, and, while

* "Take of Granulated Zinc *sixteen ounces* [avoirdupois]; Sulphuric Acid *twelve fluidounces* [Imperial measure]; Distilled Water *four pints* [Imp. meas.]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [av.], or *a sufficiency*. Pour the sulphuric acid previously mixed with the water on the zinc contained in a porcelain basin, and, when effervescence has nearly ceased, aid the action by heat. Test a few drops of the resulting liquid for iron by adding excess of ammonia and then sulphydrate of ammonium, when a black precipitate will be produced if iron be present. In the latter case filter the remainder of the fluid into a gallon bottle, and add gradually with constant agitation the solution of chlorine until the fluid acquires a permanent odor of chlorine. Add now with continued agitation the carbonate of zinc until a brown precipitate appears and the whole of the iron is thus precipitated. Let the precipitate subside, filter the solution, evaporate till a pellicle forms on the surface, and set aside to crystallize. Dry the crystals by exposure to the air on filtering paper placed on porous tiles. More crystals may be obtained by again evaporating the mother-liquor. If no iron be present, filter, and evaporate, etc., at once." *Br.* 1885.

hydrogen escapes with rapid effervescence, oxygen combines with the zinc and the acid, generating zinc sulphate. From this it will be perceived that *hydrogen* is a collateral product of the process. The proportion of the zinc to the strong acid in the process is as 4 to 5·53. The molecular weights give the ratio of 4 to 6 almost exactly,—which indicates that the metal is somewhat in excess. If the materials are mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This may be avoided by commencing the solution of zinc with a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger by the addition, at intervals, of small portions of fresh acid. As the zinc of commerce generally contains iron, this would contaminate the product, unless precautions were taken to prevent it. Hence the addition of chlorine, which reacts with ferrous sulphate to form ferric sulphate and ferric chloride, which, upon the addition of zinc carbonate, yield sulphuric acid and chlorine to the zinc, ferric oxide being deposited and carbonic acid set free. The former is separated by filtration, the latter escapes during the evaporation, the additional zinc sulphate crystallizes with that first formed, and the zinc chloride remains in the mother-waters.

Preparation on the Large Scale. Impure zinc sulphate, as it occurs in commerce, is called *white vitriol.* It is manufactured by roasting *blende* (native zinc sulphide) in a reverberatory furnace. This mineral, besides zinc sulphide, contains small quantities of iron, copper, and lead sulphides, and by roasting is converted, in consequence of the oxidation of its constituents, into zinc sulphate, mixed with iron, copper, and lead sulphates. The roasted matter is then lixiviated; and the solution obtained, after having been allowed to settle, is concentrated by evaporation, so that, on cooling, it may concrete into a white crystalline mass. In this state it always contains ferrous sulphate, and sometimes a small proportion of copper sulphate. It may be purified from these metals by dissolving it in water and boiling the solution with zinc oxide, which converts the iron and copper sulphates, by precipitating their bases, into zinc sulphate. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron. Prof. F. Stolba recommends a process which has been used successfully for the purification of zinc sulphate by the use of zinc carbonate and zinc permanganate. (See *A. J. P.*, 1877, p. 72.)

Properties. Zinc sulphate is in "colorless, transparent, rhombic crystals, without odor, and having an astringent, metallic taste. Efflorescent in dry air. Soluble in 0·6 part of water at 15° C. (59° F.), and in 0·2 part of boiling water; also soluble in about 3 parts of glycerin; insoluble in alcohol. When rapidly heated, the salt melts. At a higher temperature it is partly decomposed, losing both water and sulphuric acid. When very gradually heated to 50° C. (122° F.), it loses 5 molecules of its water (31·3 per cent.), without melting. At 100° C. (212° F.), a sixth molecule is lost, while the last may be removed by a current of dry air at 110° C. (230° F.). The aqueous solution gives an acid reaction with litmus paper. A 5-per-cent. aqueous solution yields a pure white precipitate with potassium ferrocyanide test-solution, also with ammonium sulphide test-solution, and with barium chloride test-solution. If a small portion of the salt be moistened with a drop of cobaltous nitrate test-solution, and heated before the blowpipe, it will assume a vivid green color. No residue should be left on dissolving 1 Gm. of the salt in 20 C.c. of water (absence of *lead* and *other insoluble matters*). The aqueous solution (1 in 20), after being acidulated with hydrochloric acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *copper*, etc.). The aqueous solution should yield with ammonium carbonate test-solution a pure white precipitate, which should redissolve completely in an excess of the reagent (absence of *iron*, *aluminum*, *calcium*, etc.). If from this solution in ammonium carbonate test-solution the zinc be completely precipitated by ammonium sulphide test-solution, the filtrate should leave no fixed residue on evaporation (absence of *alkalies*, *magnesium*, etc.). The aqueous solution (1 in 20) should not be rendered turbid by silver nitrate test-solution (absence of *chloride*). If 1 Gm. of Zinc Sulphate, in small fragments, be agitated for some time with 10 C.c. of alcohol, the filtrate should not redden moistened blue litmus paper (absence of *free acid*)." *U. S.* "Colorless transparent prismatic crystals with a strong metallic styptic taste. Soluble in less than an equal weight of cold *water*. It affords the reactions characteristic of zinc and of sulphates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, aluminium,

calcium, magnesium, sodium, potassium, ammonium, or acetates, and only the slightest reactions with the tests for iron or chlorides." *Br.* Its crystals have considerable resemblance to those of magnesium sulphate. It effloresces slightly in dry air, and, though neutral in composition, reddens vegetable blues. When heated it dissolves in its water of crystallization, which gradually evaporates; and by a prolonged ignition the whole of the acid is expelled, and the zinc oxide left. The alkaline carbonates precipitate the metal in the state of white carbonate. Pure zinc sulphate is precipitated white by potassium ferrocyanide and ammonium sulphydrate. What is thrown down by barium chloride or lead acetate (barium sulphate or lead sulphate) is not dissolved by nitric acid. If copper be present, ammonia will produce a blue tinge; if iron, the potassium ferrocyanide will cause a bluish-white precipitate instead of a white one, and tincture of galls a purple color. Cadmium and arsenic may be detected by acidulating the solution with sulphuric acid and passing a stream of hydrogen sulphide through it; when, if either of these metals be present, it will be thrown down as a yellow sulphide. Zinc sulphate is incompatible with alkalies and alkaline carbonates, sulphides, lime water, the soluble lead salts, and astringent infusions.

The impure commercial variety of zinc sulphate is in the form of irregular white masses having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by ferric oxide. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition. Crystallized zinc sulphate consists of one sulphuric acid group SO_4, one atom of zinc, and seven molecules of water. The white vitriol of commerce contains but three molecules of water.

Medical Properties and Uses. This salt is tonic, astringent, and, in large doses, a prompt emetic, producing very little depression, and much used when it is desired simply to evacuate the stomach. In *gastric catarrh* it is sometimes useful, in the dose of one-quarter of a grain (0·016 Gm.) before meals, in pill. It was formerly used in *night-sweats*, *epilepsy*, *chorea*, and other nervous diseases, but has now entirely passed out of vogue as a remedy in such affections. As an astringent it is chiefly employed externally. Its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in *fluor albus* and *gonorrhœa*, and as a collyrium in *ophthalmia*, also as a stimulant application to *ulcers* both of the mucous membrane and of the skin. Dose, from one-quarter to one-half grain (0·018–0·037 Gm.); as an emetic, from ten to thirty grains (0·65–1·95 Gm.). When used as a collyrium, an injection, or a gargle, or as a wash for indolent ulcers, from one to three grains (0·065–0·2 Gm.) or more may be dissolved in a fluidounce (30 C.c.) of water. For medicinal purposes the crystallized salt only should be used. Prof. Simpson, of Edinburgh, employed dried zinc sulphate in the form of powder, paste, or ointment, as a powerful, rapid, manageable, and safe caustic in indurated inflammatory ulcers of the cervix uteri; in *lupus;* in *ulcerous forms of skin diseases;* and in removing *urethral caruncles*, *condylomata*, *warty excrescences*, etc. The dried salt should be finely levigated. The caustic paste is made by incorporating an ounce of the powder with a drachm of glycerin; and the caustic ointment, by thoroughly mixing the same quantity of the powder with two drachms of lard. (See *Am. Journ. Med. Sci.*, April, 1857, p. 485.)

Zinc sulphate, in an overdose, acts as an irritant poison. Besides vomiting and incessant retching, it produces anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt, the patient being generally relieved by its prompt expulsion in vomiting. Death is said to have been caused, however, by an ounce and a half. The treatment consists in the free administration of bland drinks, the use of opium to allay irritation, and the employment of the usual antiphlogistic remedies should symptoms of inflammation arise.

ZINCI SULPHOCARBOLAS. Br. Zinc Sulphocarbolate.

$Zn(C_6H_5SO_4)_2, H_2O$. (ZĬN'CĪ SŬL-PHŌ-CĂR'BŌ-LĂS.)

"Zinc Sulphocarbolate, or zinc phenol-para-sulphonate, $Zn(OH.C_6H_4SO_3)_2,H_2O$, may be obtained by heating a mixture of phenol and sulphuric acid, and saturating the product with zinc oxide." *Br.*

It is officially described as in "colorless, transparent, tabular, efflorescent crystals; soluble in 2·5 parts of *alcohol* (90 per cent.), and in 2 parts of *water*. The aqueous solution is colored violet by *test-solution of ferric chloride*, and affords a white precipitate with *solution of ammonium hydrosulphide*. It should yield no characteristic reaction with the tests for lead, copper,

cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, acetates, or chlorides, and only the slightest reactions with the tests for sulphates." *Br.*

Medical Properties. Zinc sulphocarbolate is not used internally, but has been employed as an antiseptic astringent stimulant to indolent or foul *ulcers*, and in subacute inflammations of the mucous membrane. The solutions used may be a little stronger than those of zinc sulphate employed for similar purposes.

ZINCI VALERIANAS. U. S., Br. Zinc Valerianate.

$Zn(C_5H_9O_2)_2.2H_2O$; 302·56. (ZĬN'CĪ VA-LĒ-RI-Ā'NĂS.) $Zn(C_5H_9O_2)_2.2H_2O$; 302·9.

"Zinc Valerianate should be kept in small, well-stoppered bottles." *U. S.* "Zinc Valerianate, or zinc iso-valerianate, $Zn(C_5H_9O_2)_2$, may be prepared by saturating iso-valerianic acid with zinc carbonate, or by the interaction of zinc sulphate and sodium iso-valerianate." *Br.*

Zincum Valerianicum, *P. G.;* Valerianas Zincicus; Valérianate de Zinc, *Fr.;* Baldriansaures, Zinkoxyd, *G.*

Zinc valerianate was formerly included among the preparations of the U. S. Pharmacopœia, but at the revision of 1880 no process was inserted. The British Pharmacopœia no longer gives a formula for its preparation: for former formulæ, see foot-note.*

Properties. This salt is in "white, pearly scales, having the odor of valerianic acid, and a sweetish, astringent, and metallic taste. On exposure to the air, it slowly loses valerianic acid. Soluble, at 15° C. (59° F.), in about 100 parts of water, and in 40 parts of alcohol; somewhat more soluble in absolute alcohol. Boiling renders the solution turbid from loss of acid and formation of a basic salt. When heated, the salt melts. At a higher temperature it is decomposed, giving off inflammable vapors, and finally leaving a residue of zinc oxide. The aqueous solution reddens blue litmus paper. If 0·5 Gm. of Zinc Valerianate be dissolved in a mixture of 0·5 C.c. of hydrochloric acid and 4·5 C.c. of water, the valerianic (isovalerianic) acid will be liberated, and float as an oily layer on the surface of the liquid. After its removal, the clear solution should be neither colored nor rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.). Zinc Valerianate should dissolve without residue in ammonia water (absence of *iron*, etc.). If from this solution the zinc be completely precipitated by ammonium sulphide test-solution, the precipitate should have a pure white color, and the filtrate should leave no fixed residue on evaporation (absence of *alkalies*, *magnesium*, etc.). If 0·5 Gm. of Zinc Valerianate be triturated with 2 C.c. of water and 0·2 C.c. of ferric chloride test-solution added, the filtrate should not show a red color (absence of *acetate*). If a concentrated solution of copper acetate in water be added to a concentrated, aqueous solution of Zinc Valerianate, the mixture should remain perfectly clear (absence of *butyrate*)." *U. S.* "In white pearly tabular crystals, with a disagreeable odor, and a metallic taste; very slightly soluble in cold *water* or in *ether*, soluble in hot *water* and *alcohol* (90 per cent.). On heating to redness, after moistening with a small quantity of *nitric acid*, it should yield not less than 26 nor more than 30 per cent. of zinc oxide. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, acetates, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates. When heated with *diluted sulphuric acid* it gives a distillate which, when mixed with *solution of copper acetate*,

* "Take of Valerianate of Soda *two troyounces and a half;* Sulphate of Zinc *two troyounces and four hundred and twenty grains;* Distilled Water *a sufficient quantity.* Dissolve the salts separately, each in twenty fluidounces of Distilled Water, and, having heated the solutions to 212° F., mix them, and set the mixture aside to crystallize. Decant the mother-water from the crystals, and put them upon a filter in a funnel to drain. Mix the mother-water and the drainings, evaporate at a heat not exceeding 200° F. to four fluidounces, and again set aside to crystallize. Add the crystals, thus obtained, to those in the funnel, wash the whole with a little Distilled Water, and, having removed them with the filter, spread them on bibulous paper, and dry them with a heat not exceeding 200° F." *U. S.* 1870.

"Take of Sulphate of Zinc *five ounces and a half* [avoirdupois]; Valerianate of Sodium *five ounces* [av.]; Distilled Water *a sufficiency.* Dissolve the Sulphate of Zinc and the Valerianate of Sodium, each, in two pints [Imperial measure] of the Water; heat both solutions to near the boiling point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-liquor at a heat not exceeding 200° F., till it is reduced to four [fluid]ounces; cool again, remove the crystals which have formed, and add them to those which have been already obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold Distilled Water, till the washings give but a very feeble precipitate with chloride of barium. Let them now be again drained, and dried on filtering paper at ordinary temperatures." *Br.*

These formulas are essentially the same as the formula of the late Dublin Pharmacopœia. In the formation of the salt a double decomposition takes place between the reacting salts, resulting in the production of zinc valerianate and sodium sulphate. Upon mixing the hot solutions, crystals of the sparingly soluble zinc valerianate form on the surface of the liquid; and during the progress of its concentration to one-tenth, more of them are successively produced. These are then washed with cold distilled water to separate adhering sodium sulphate, drained on a filter, and dried.

does not immediately affect the transparency of the liquid, but forms after a little time oily drops, which gradually pass into a bluish-white crystalline deposit (absence of butyrates)." *Br.* The salt, as obtained by the British 1885 and U. S. P. 1870 formulas, contained one mol. of water; but when formed by saturating zinc carbonate, made into a paste with water, with valerianic acid, it contains six mols. of water, and, when dried at 50° C. (122° F.), perfectly resembles the official salt. (Wittstein.) Other authorities (Flückiger, *Pharm. Chem.*, and Roscoe and Schorlemmer's *Chem.* vol. iii. part i.) give the formula of the stable crystallized salt as $Zn(C_5H_9O_2)_2 + 2H_2O$. Zinc acetate impregnated with oil of valerian has been substituted for this salt; but at present, from the relative costliness of the oil, there is no inducement to this fraud. Zinc butyrate has been sold in Paris for the valerianate, and is so like it as not to be distinguished by its physical properties. The two salts, however, may be discriminated by adding a concentrated solution of the acid of the suspected salt, obtained by distillation with sulphuric acid, to a concentrated solution of copper acetate. If the acid be the butyric, its addition to the solution of the acetate will disturb the transparency of the latter, by the formation of a bluish-white precipitate; if it be the valerianic, no change will be produced. (Larocque and Huraut, *Journ. de Pharm.*, 3e sér., ix. 430.)

Medical Properties. Zinc valerianate was proposed as a remedy, on theoretical grounds, by Prince Louis-Lucien Bonaparte. Upon trial it was found to possess antispasmodic properties, and has been used in *diabetes insipidus*. By some of the Italian physicians it has been extolled as a remedy in *neuralgia*. Dr. F. Devay, of Lyons, found it useful in *epilepsy*, and in the nervous affections which accompany *chlorosis*. The dose is from one to two grains (0·065–0·13 Gm.), repeated several times a day, and given in the form of pill.

ZINGIBER. U. S., Br. Ginger.

(ZĬN'ĢI-BĘR.)

"The rhizome of Zingiber officinale, Roscoe (nat. ord. Scitamineæ)." *U. S.* "The scraped and dried rhizome of Zingiber officinale, Roscoe."* *Br.*

Rhizoma Zingiberis, *P. G.;* Gingembre, *Fr.;* Ingwer, *G.;* Zenzero, *It.;* Gengibre, *Sp.*

Zingiber officinale. Roscoe, *Trans. Lin. Soc.* (1807) viii. 348; Carson, *Illust. of Med. Bot.* ii. 55, pl. 98.—*Amomum zingiber.* L. *Sp. Plant.* 1753, 1; *B. & T.* 270. The ginger plant has a biennial or perennial, creeping rhizome, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and, like it, is clothed with oval acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow color, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East, and at Sierra Leone in Africa. The flowers have an aromatic smell, and the stems when bruised are slightly fragrant; but it is in the rhizome that the virtues of the plant reside. This is fit to be dug up when a year old. In the West Indies the ginger crop is gathered in January and February, after the stems have withered. After having been properly cleansed, the root is scalded in boiling water, in order to destroy its vitality, and is then rapidly dried. Thus prepared, it constitutes the ordinary ginger of commerce, or *black ginger*, as it is sometimes called, from the darkish color acquired in the process. It is imported chiefly from Calcutta, and is known to the druggists by the name of East India ginger; but recently considerable quantities have been brought from Africa, and some probably reaches us from the West Indies. In Jamaica another variety is prepared by selecting the best roots, depriving them of their epidermis, and drying them separately and carefully in the sun. This is called in the books *white ginger*, and is most highly valued. It reaches us from England, where it is said to undergo some further preparation, by which its appearance is improved. It is usually called in our markets *Jamaica ginger*. The root is also at present imported from the East Indies deprived of the

* A ginger-like root occurs in Siam, which was supposed in 1887, by Sir J. Hooker, to be yielded by a new species of Alpinia, *A. zingiberina*. According to Mr. J. G. Baker, however, this plant is not distinct from *A. galanga*, which yields the greater or Java galangal root of commerce. It was long ago pointed out that ordinary so-called preserved ginger from China has larger rhizomes than are common with *Zingiber officinale;* and Mr. C. Ford, Director of the Botanical Garden at Hong-Kong, has finally succeeded in getting the ginger plant of China to flower, and in identifying it as *Alpinia galanga*. (See *Kew Bulletin*, 1891.)

epidermis. Considerable quantities are brought immediately from the West Indies in a recent state, and sold by the confectioners. A preserve is made from ginger by selecting the roots while young and tender, depriving them of their cortical covering, and boiling them in syrup. This is occasionally imported from the East and West Indies. This *preserved ginger*, when good, is translucent and tender. An interesting paper describing the collection of Jamaica ginger, by F. B. Kilmer, will be found in *A. J. P.*, 1898, 65.

The *recent root* is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash color with circular rugæ, internally yellowish white and fleshy. It sometimes begins to grow when kept in a damp atmosphere. The *common* or *black ginger* is of the same general shape, but has a dark ash-colored wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black color, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown color. This variety is most extensively used. The *Jamaica* or *white ginger* differs in being entirely deprived of epidermis, and white or yellowish white on the outside. The pieces are rounder and thinner, in consequence of the loss of substance in their preparation. They afford when pulverized a beautiful yellowish-white powder, which is brought from Liverpool in jars. This variety is firm and resinous, and has more of the sensible qualities of ginger than the black. The uncoated ginger of the East Indies resembles the Jamaica, but is darker, being gray rather than white. As the Jamaica commands a much higher price than even the uncoated East India production, the latter is occasionally altered to simulate the former. This is sometimes done by coating the exterior with calcium sulphate or carbonate, sometimes by bleaching, by which not only the exterior but also the internal parts are rendered whiter than in the unprepared root. Trommsdorff found, in a specimen which he examined, evidences of the presence of chlorides, sulphates, and calcium, and concluded that the bleaching was effected by chlorine, or by calcium chloride and sulphuric acid. Having macerated some black ginger in water, deprived it of the cortical portion, treated it for twenty-four hours with sulphuric acid diluted with nine times its weight of water, and finally placed it in a mixture of calcium chloride and water, in which it was allowed to remain for two days, he found it, upon being washed and dried, to present an appearance closely resembling that of the finest white ginger, both on the surface and internally. (*Ann. der Pharm.*, xvii. 98.) According to Brande, ginger is often washed in whiting and water; and Pereira states that it is sometimes bleached by exposure to the fumes of burning sulphur.* There is good reason to believe that ginger is sometimes sent into commerce after it has been partially exhausted of its activity by treatment with alcohol. For methods of detecting this fraud, see *The Analyst*, 1893, 197; *A. J. P.*, 1894, 342.

* Clifford Richardson has published in *Bulletin No. 13*, Part 2, of the U. S. Department of Agriculture, 1887, some accurate analyses of whole ginger root from various sources, which are here given:

Source.	Water.	Ash.	Volatile Oil.	Fixed Oil and Resin.	Starch.	Crude Fibre.	Albuminoids.	Undetermined.	Total.
Calcutta	9·60	7·02	2·27	4·58	49·34	7·45	6·30	13·44	100·00
Cochin	9·41	3·39	1·84	4·07	53·33	2·05	7·00	18·91	100·00
Unbleached Jamaica	10·49	3·44	2·03	2·29	50·58	4·74	10·85	15·58	100·00
Bleached Jamaica, London	11·00	4·54	1·89	3·04	49·34	1·70	9·28	19·21	100·00
Bleached Jamaica, American	10·11	5·58	2·54	2·69	50·67	7·65	9·10	11·66	100·00
Bleached Jamaica	9·10	4·36	0·96	3·09	46·16	3·15	5·25	27·93	100·00

African and Indian gingers are stronger than Jamaica ginger. In an assay by Mr. Frank M. Siggins (*A. J. P.*, June, 1888), various commercial varieties yielded resin as below:

I. Jamaica, unbleached	5·0 per cent.
II. Jamaica, bleached	4·8 per cent.
III. East India	6·65 per cent.
IV. East India	6·57 per cent.
V. African	6·17 per cent.
VI. African	7·0 per cent.

The yield of resin forms a fair basis for estimating the strength of the varieties.

See also a table of percentages of moisture, ash, and oleoresin by Glass. (*A. J. P.*, 1897, 320.)

General Properties. The U. S. Pharmacopœia describes ginger as "about 5 to 10 Cm. long, 10 to 15 Mm. broad, and 4 to 8 Mm. thick, flattish, on one side lobed or clavately branched; deprived of the corky layer; pale buff-colored, striate, breaking with a mealy, rather fibrous fracture, showing numerous small, scattered resin-cells and fibro-vascular bundles, the latter enclosed by a nucleus sheath; agreeably aromatic, and of a pungent and warm taste." *U. S.* The odor of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost, by exposure. The virtues of ginger are extracted by water and alcohol.

The peculiar flavor of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of pure white starch may be obtained from it. The volatile oil, examined by A. Papousek, was yellow, of the odor of ginger, and of a hot aromatic taste. Its sp. gr. was 0·893, and its boiling point 246·1° C. (475° F.). Deprived of water by distillation over phosphoric oxide, it consisted of carbon and hydrogen, with the formula $C_{10}H_{16}$, and therefore belongs to the terpenes. Thresh considers that the essential oil is mainly made up of a hydrocarbon, $C_{15}H_{24}$, or isomers of it, which boil at from 245° to 270° C. (*Pharm. Journ. Trans.*, No. 586, 1881.) Schimmel & Co., in a recent report (April, 1897), state that the essential oil contains *camphene* and *phellandrene*, and hence the terpenes have the formula $C_{10}H_{16}$, as first stated. Flückiger obtained from one hundred and twelve pounds of Jamaica ginger four and a half ounces of the oil, or about one-quarter of one per cent. He states, however, that Messrs. Schimmel & Co., of Leipsic, informed him that they obtained as much as 2·2 per cent. from good ginger. (*Pharmacographia*, 2d ed., p. 637.) Those pieces of ginger which are very fibrous, light and friable, or worm-eaten, should be rejected. The commercial powder of ginger is very frequently adulterated, rice starch, powdered ginger which has been exhausted in making preparations, and even brick-dust and chalk, being used, and the loss of pungency made good by the addition of capsicum or mustard.

Medical Properties and Uses. Ginger is a grateful stimulant and carminative, and is often given in *dyspepsia*, *flatulent colic*, and the feeble state of the alimentary canal attendant upon *atonic gout*. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. When chewed it produces much irritation of the mouth, and a copious flow of saliva; and when snuffed up the nostrils in powder it excites violent sneezing. Externally it is rubefacient. Dr. Archibald G. Thomson (*Phila. Polyclinic*, vi. 1897) reports a case of complete blindness following the ingestion of one and a half quarts of Jamaica ginger essence, and ending in permanent amblyopia. It may be given in powder or in infusion. The dose of the former is from ten grains to a scruple (0·65–1·3 Gm.) or more. The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces (30–60 C.c.). A fluid extract and an oleoresin of ginger are now official, and are very convenient preparations. (See *Extractum Zingiberis Fluidum* and *Oleoresina Zingiberis*.) The dose of the former may be from ten to thirty minims (0·6–1·9 C.c.), that of the latter from two to five minims (0·12–0·3 C.c.). There is also an official tincture, the dose of which is about a fluidrachm (3·7 C.c.).

PART II.

SECTION I.

NATIONAL FORMULARY OF UNOFFICIAL PREPARATIONS.

THE American Pharmaceutical Association, realizing the necessity for greater uniformity in the formulas of many well-known and largely used preparations, has issued a formulary (1896), which is here reproduced, in the hope that it will be universally accepted by pharmacists and physicians, and a much-needed reform thus inaugurated. In prescriptions these formulas should be designated **N. F.** to distinguish them. The abbreviation F. placed before a number—thus, (F. 250)—means a reference to the number of the formula,—*i.e.*, 250.

1. ACETUM AROMATICUM. *N. F.*

Aromatic Vinegar.

Oil of Lavender	0.5 Cc.
Oil of Rosemary	0.5 Cc.
Oil of Juniper	0.5 Cc.
Oil of Peppermint	0.5 Cc.
Oil of Cinnamon (Cassia)	0.5 Cc.
Oil of Lemon	1 Cc.
Oil of Cloves	1 Cc.
Alcohol	175 Cc.
Acetic Acid (U. S. P.)	175 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Oils in the Alcohol, add the Acetic Acid, and, lastly, enough Water to make *one thousand* (1000) *cubic centimeters*. Warm the turbid mixture during several hours, at a temperature not exceeding 70° C. (158° F.), taking care that it shall not suffer loss by evaporation. Then set it aside for a few days, occasionally agitating, and filter.

2. ACETUM LOBELIÆ. *N. F.*

(U. S. P., 1880.)

Vinegar of Lobelia.

Lobelia, in No. 30 powder	100 Gm.
Diluted Acetic Acid (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Moisten the powder with *fifty* (50) *cubic centimeters* of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

3. ACETUM SANGUINARIÆ. *N. F.*

(U. S. P., 1880.)

Vinegar of Sanguinaria.

Sanguinaria, in No. 30 powder	100 Gm.
Diluted Acetic Acid (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Moisten the powder with *fifty* (50) *cubic centimeters* of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until *one thousand* (1000) *cubic centimeters* of percolate are obtained.

4. ACIDUM CARBOLICUM IODATUM. *N. F.*

Iodized Carbolic Acid.

Phenol Iodatum. Iodized Phenol.

Iodine, reduced to powder	20 Gm.
Carbolic Acid	60 Gm.
Glycerin	20 Gm.

Introduce the Iodine into a flask, add the Carbolic Acid, previously melted, then the Glycerin, and digest the mixture at a gentle heat, frequently agitating, until the Iodine is dissolved.

Keep the product in glass-stoppered vials, in a dark place.

5. ACIDUM CITRICUM SACCHARATUM. *N. F.*

Saccharated Citric Acid.

Citric Acid (U. S. P.), in very fine powder	625 Gm.
Sugar, in very fine powder	375 Gm.

Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles.

Note.—This Saccharate, when dissolved in water with an equal weight of Saccharated Sodium Bicarbonate (F. 341), will form a neutral solution, and it is introduced into this Formulary for the convenient preparation of Effervescent Powders (F. 319).

This Saccharate contains 62.5 per cent. of Crystallized Citric Acid.

6. ACIDUM HYPOPHOSPHOROSUM DILUTUM. *N. F.*

Diluted Hypophosphorous Acid.

Potassium Hypophosphite	208 Gm.
Tartaric Acid	300 Gm.
Distilled Water	588 Gm.
Diluted Alcohol (U. S. P.)	600 Gm.

Dissolve the Potassium Hypophosphite in the Distilled Water and the Tartaric Acid in the Diluted Alcohol. Mix the two solutions in a flask, cork the latter well, and put it aside in a cold place during twelve hours. Then carefully decant the liquid into a funnel, the neck of which contains a pellet of absorbent cotton, or, if necessary, pass the liquid through a filter, care being taken that it shall not suffer loss by evaporation. Weigh the filtrate, which contains *ten* (10) *per cent.* of hypophosphorous acid, in a tared capsule, and evaporate the alcohol by means of a water-bath, at a temperature not exceeding 60° C. (140° F.). Then allow the liquid to cool, and add enough Distilled Water to restore the original

weight of the filtrate. Preserve the product in well-stoppered bottles.

Note.—This acid is now official in the U. S. P.; but the formula is retained because it may be now and then convenient or necessary to make it. If a 50 per cent. acid is required, the concentration may be cautiously continued until the desired percentage has been attained. A 50 per cent. acid has a specific gravity of about 1.406 at 15° C. (59° F.).

7. ACIDUM METAPHOSPHORICUM DILUTUM. *N. F.*

Diluted Metaphosphoric Acid.

Acidum Phosphoricum Glaciale Dilutum. Diluted Glacial Phosphoric Acid.

Glacial Phosphoric Acid	100 Gm.
Distilled Water, *enough to make*	1000 Cc.

Dissolve the Acid in the Water, without heat.

This preparation should be kept in a cool and dark place, and should not be prepared in larger quantity than may be consumed within a few months.

Note.—The resulting product contains about 10 per cent. of metaphosphoric acid, provided the glacial acid was free from impurities. That which is sold in form of glassy lumps is usually of sufficient purity. The variety in form of round sticks is more or less impure, containing generally more than 15 per cent. of phosphate of sodium. If this variety is alone available, a proportionately larger quantity must be taken, to be determined, if time permits, by an assay of the free acid present. If no special accuracy is required, about 115 Gm. of this variety of the acid may be reckoned to be equivalent to the quantity directed in the above given formula.

8. ACIDUM TARTARICUM SACCHARATUM. *N. F.*

Saccharated Tartaric Acid.

Tartaric Acid (U. S. P.), in very fine powder	675 Gm.
Sugar, in very fine powder	325 Gm.

Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles.

Note.—This Saccharate, when dissolved in water with an equal weight of Saccharated Sodium Bicarbonate (F. 341), will form a neutral solution, and it is introduced into the Formulary for the convenient preparation of Effervescent Powders (F. 319).

This Saccharate contains 67.5 per cent. of Tartaric Acid.

9. AMYLUM IODATUM. *N. F.*

(U. S. P., 1880.)

Iodized Starch.

Starch	95 Gm.
Iodine	5 Gm.
Distilled Water	a sufficient quantity.

Triturate the Iodine with a little Distilled Water; add the starch gradually and continue triturating until the compound assumes a uniform blue color, approaching to black. Dry it at a temperature not exceeding 40° C. (104° F.), and rub it to a fine powder.

Iodized Starch should be preserved in glass-stoppered vials.

10. AQUA HAMAMELIDIS SPIRITUOSA. *N. F.*

Hamamelis Water.

Witchhazel Water. Witchhazel Extract.

Hamamelis, shoots and twigs	10,000 Gm.
Water	20,000 Cc.
Alcohol	1,500 Cc.

Place the Hamamelis in a still, add the Water and Alcohol, and allow the mixture to macerate during twenty-four hours. Distil *ten thousand* (10,000) *cubic centimeters* by applying direct heat, or preferably, by means of steam.

Note.—This preparation should be made only from the fresh young twigs of Hamamelis, which are collected for this purpose preferably, when the plant is in flower, in the late autumn of the year.

11. AQUA SEDATIVA. *N. F.*

Sedative Water.

Lotio Ammoniacalis Camphorata (Codex). *Eau Sédative de Raspail.*

Ammonia Water (U. S. P.)	125 Cc.
Spirit of Camphor (U. S. P.)	12 Cc.
Sodium Chloride	65 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Chloride in about *five hundred* (500) *cubic centimeters* of Water, add the Ammonia Water and Spirit of Camphor, and finally enough Water to make *one thousand* (1000) *cubic centimeters*.

Shake the liquid when it is to be dispensed.

12. BALSAMUM TRAUMATICUM. *N. F.*

Traumatic Balsam.

Turlington's Balsam. Friar's Balsam.

Benzoin, in coarse powder	100 Gm.
Storax	35 Gm.
Balsam of Tolu	35 Gm.
Balsam of Peru	16 Gm.
Aloes, in coarse powder	8 Gm.
Myrrh, in coarse powder	8 Gm.
Angelica Root, in moderately coarse powder	4 Gm.
Alcohol	1000 Cc.

Macerate the substances with the Alcohol during ten days, frequently agitating; then filter.

Note.—The official *Tinctura Benzoini Composita* is a simplified preparation intended to replace the above compound.

13. BISMUTHI OXIDUM HYDRATUM. *N. F.*

Hydrated Oxide of Bismuth.

Bismuth Subnitrate	300 Gm.
Nitric Acid (U. S. P.)	500 Gm.
Ammonia Water (U. S. P.)	600 Gm.
Sodium Bicarbonate	50 Gm.
Distilled Water	a sufficient quantity.

Mix the Bismuth Subnitrate with *two hundred* (200) *cubic centimeters* of Distilled Water in a quart flask, add *four hundred and fifty* (450) *cubic centimeters* of Nitric Acid, and promote the solution of the salt by agitation, and, if necessary, by a gentle heat. Pour the solution into *six thousand* (6000) *cubic centimeters* of Distilled Water previously acidulated with *fifty* (50) *grammes* of Nitric Acid, and filter the liquid through absorbent cotton. Mix the Ammonia Water with *twelve thousand* (12,000) *cubic centimeters* of Distilled Water in a glazed vessel of double that capacity, and pour into it, slowly and with constant stirring, the bismuth solution. Let the mixture stand during four hours, so that the precipitate may subside, then pour off the supernatant liquid, and wash the precipitate four times more by decantation with Distilled Water, the Sodium Bicarbonate being dissolved in the last wash-water. Pour the precipitate upon a wetted muslin strainer, and wash it with Distilled Water, until the washings run off tasteless. Transfer the strainer to a warm place, so that the precipitate may dry. Then rub the latter to powder, and keep it in well-stoppered bottles.

Note.—Hydrated Oxide of Bismuth is sometimes demanded in the form of a creamy mixture with water, under the name of *Cremor Bismuthi* or *Cream of Bismuth*. This may be prepared by triturating 20 parts of the Oxide with 80 parts of Water.

14. BOROGLYCERINUM. *N. F.*

Boroglycerin.

Glyceryl Borate. Boroglyceride.

Boric Acid, in powder	620 Gm.
Glycerin	920 Gm.

Heat the Glycerin in a tared porcelain capsule to a temperature not exceeding 150° C. (302° F.), and add the Boric Acid in portions, constantly stirring. When

all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has become reduced to a weight of *one thousand* (1000) *grammes*, pour it out on a flat surface previously coated with a very small quantity of petrolatum, let it cool, cut it into pieces and transfer them immediately to bottles or jars, which should be well-stoppered.

Note.—The official Glycerite of Boroglycerin may be made from this by adding an equal weight of Glycerin to the finished Boroglycerin while it is still warm.

15. CAFFEINÆ SODIO-BENZOAS. *N. F.*

Caffeine Sodio-Benzoate.

Caffeine	50 Gm.
Sodium Benzoate	50 Gm.
Alcohol	a sufficient quantity.

Triturate the Caffeine with the Sodium Benzoate and a sufficient quantity of Alcohol to a smooth paste, and dry this by exposure in a moderately warm place. Rub the dry mass to powder, and keep it in well-stoppered bottles.

Note.—The product contains 50 per cent. of Caffeine, and is soluble in 2 parts of water.

16. CAFFEINÆ SODIO-SALICYLAS. *N. F.*

Caffeine Sodio-Salicylate.

Caffeine	50 Gm.
Sodium Salicylate	50 Gm.
Alcohol	a sufficient quantity.

Triturate the Caffeine with the Sodium Salicylate and a sufficient quantity of Alcohol to a smooth paste, and dry this by exposure in a moderately warm place. Rub the dry mass to powder, and keep it in well-stoppered bottles.

Note.—The product contains 50 per cent. of Caffeine, and is soluble in 2 parts of water.

17. CARBASUS CARBOLATA. *N. F.*

Carbolized Gauze.

Resin, in coarse powder	40 Gm.
Castor Oil	5 Gm.
Carbolic Acid	10 Gm.
Alcohol	225 Gm.
Gauze muslin	a sufficient quantity.

Dissolve the Resin, Castor Oil, and Carbolic Acid in the Alcohol. Immerse in the mixture loosely-folded pieces of gauze muslin, allow them to become thoroughly saturated, then take them out and press out the excess of liquid, until the weight of the impregnated gauze amounts to *one hundred and seventy* (170) *grammes*, for every *one hundred* (100) *grammes* of the original fabric. Spread out the pieces horizontally, and as soon as the Alcohol has nearly all evaporated, fold and wrap the pieces in paraffin paper, and preserve them in air-tight receptacles.

The impregnated Gauze, when dry, contains about 2.5 per cent. of Carbolic Acid.

Note.—The most suitable brands of gauze muslin for making carbolized or other antiseptic gauze are those known in the market as "Stillwater," or "Lehigh E."

18. CARBASUS IODOFORMATA. *N. F.*

Iodoform Gauze.

Iodoform	10 Gm.
Ether (U. S. P.)	40 Gm.
Alcohol	40 Gm.
Tincture of Benzoin (U. S. P.)	5 Gm.
Glycerin	5 Gm.
Gauze Muslin	a sufficient quantity.

Dissolve the Iodoform in the Ether, then add the Alcohol, Tincture of Benzoin, and Glycerin. Immerse in a weighed quantity of this solution, contained in a suitable vessel, the exact amount of Gauze Muslin required to absorb the whole of it, to produce a product of a prescribed percentage of iodoform, work it about with a pestle so as to impregnate it uniformly; then take it out, and hang it up to dry, in a horizontal position, and in a dark place. Lastly, wrap it in paraffin paper and preserve it in air-tight receptacles.

Note.—To calculate the amount of muslin and of iodoform solution required to obtain a product approximately of any required p-rcentage of iodoform, let x denote this required percentage. Then take of the above Iodoform Solution *ten* (10) *times* this quantity (or 10 x). Also multiply the required percentage (x) by *three* (3), divide the resulting product by *two* (2), and subtract the quotient from *one hundred* (100). The remainder represents the number of parts by weight of Gauze Muslin to be used. Regarding the most suitable kind of gauze muslin, see note to *Carbasus Carbolata* (F. 17).

19. CERATUM CAMPHORÆ COMPOSITUM. *N. F.*

Compound Camphor Cerate.

Ceratum Camphoratum. Camphor Ice.

Camphor, in coarse powder	107 Gm.
White Wax	150 Gm.
Castor Oil	250 Gm.
Spermaceti	480 Gm.
Carbolic Acid, liquefied by warming	2 Gm.
Oil of Bitter Almond	1 Gm.
Benzoic Acid	10 Gm.

Melt the White Wax and Spermaceti on a water-bath, add the Castor Oil, and afterwards the Camphor, and continue heating and stirring until the Camphor is dissolved. Then withdraw the heat, cover the vessel, and when the mixture has somewhat cooled, add the remaining ingredients, and thoroughly incorporate them by stirring. Lastly, pour the Cerate into suitable moulds.

20. CERATUM EXTRACTI CANTHARIDIS. *N. F.*

(U. S. P., 1880.)

Cerate of Extract of Cantharides.

Cantharides, in No. 60 powder	300 Gm.
Resin	150 Gm.
Yellow Wax	350 Gm.
Lard	350 Gm.
Alcohol	a sufficient quantity.

Moisten the Cantharides with *one hundred and eighty* (180) *cubic centimeters* of Alcohol, and pack firmly in a cylindrical percolator; then gradually pour on Alcohol until *one thousand eight hundred* (1800) *cubic centimeters* of percolate are obtained, or until the Cantharides are exhausted. Distil off the Alcohol by means of a water-bath, transfer the residue to a tared capsule, and evaporate it, on a water-bath, until it weighs *one hundred and fifty* (150) *grammes*. Add to this the Resin, Wax, and Lard, previously melted together, and keep the whole at a temperature of 100° C. (212° F.), for fifteen minutes. Lastly, strain the mixture through muslin, and stir it constantly until cool.

21. CERATUM SABINÆ. *N. F.*

(U. S. P., 1880.)

Savine Cerate.

Fluid Extract of Savine	25 Cc.
Resin Cerate	90 Gm.

Melt the Resin Cerate by means of a water-bath, add the Fluid Extract of Savine, and continue the heat until the Alcohol has evaporated; then remove the heat, and stir constantly until cool.

22. CHARTA CANTHARIDIS. *N. F.*

(U. S. P., 1880.)

Cantharides Paper.

White Wax	80 Gm.
Spermaceti	30 Gm.
Olive Oil	40 Gm.
Canada Turpentine	10 Gm.
Cantharides, in No. 40 powder	10 Gm.
Water	100 Cc.

Mix all the substances in a tinned vessel, and boil gently for two hours, constantly stirring. Strain through a woollen strainer without expressing, and, by means of a water-bath, keep the mixture in a shallow, flat-bottomed ves-

sel with an extended surface. Coat strips of sized paper with the melted plaster, on one side only, by passing them successively over the surface of the liquid; when dry, cut the strips into rectangular pieces.

23. CHLORAL CAMPHORATUM. *N. F.*

Camphorated Chloral.

Chloral et Camphora. Chloral and Camphor.

Chloral	50 Gm.
Camphor	50 Gm.

Mix them by agitation in a bottle, or by trituration in a warm mortar, until they are liquefied and combined.

24. COLLODIUM IODATUM. *N. F.*

Iodized Collodion.

Iodine, reduced to powder	5 Gm.
Flexible Collodion (U. S. P.)	95 Gm.

Introduce the Iodine into a bottle, add the Flexible Collodion, and agitate until the Iodine is dissolved.

25. COLLODIUM IODOFORMATUM. *N. F.*

Iodoform Collodion.

Iodoform	5 Gm.
Flexible Collodion (U. S. P.)	95 Gm.

Dissolve the Iodoform in the Flexible Collodion by agitation.

26. COLLODIUM TIGLII. *N. F.*

Croton Oil Collodion.

Croton Oil	10 Gm.
Flexible Collodion (U. S. P.)	90 Gm.

Mix them.

27. COLLODIUM SALICYLATUM COMPOSITUM. *N. F.*

Compound Salicylated Collodion.

Corn Collodion.

Salicylic Acid	11 Gm.
Extract of Indian Hemp	2 Gm.
Alcohol	10 Gm.
Flexible Collodion (U. S. P.), a sufficient quantity	
To make	100 Gm.

Dissolve the Extract of Indian Hemp in the Alcohol, and the Salicylic Acid in about *fifty* (50) *grammes* of Flexible Collodion contained in a tared bottle. Then add the former solution to the latter, and finally add enough Flexible Collodion to make *one hundred* (100) *grammes.*

28. CORDIALE RUBI FRUCTUS. *N. F.*

Blackberry Cordial.

Blackberry Juice	1875 Cc.
Cinnamon, in No. 40 powder	100 Gm.
Cloves, in No. 40 powder	25 Gm.
Nutmeg, in No. 40 powder	25 Gm.
Diluted Alcohol (U. S. P.)	a sufficient quantity.
Syrup (U. S. P.)	1875 Cc.

Percolate the powdered spices with Dilute Alcohol to obtain *twelve hundred and fifty* (1250) *cubic centimeters* of tincture and add to this the Blackberry Juice. Then add *thirty* (30) *grammes* of Purified Talcum, set the mixture aside for twenty-four hours, occasionally shaking, and filter. Wash the filter with sufficient Diluted Alcohol to obtain *thirty-one hundred and twenty-five* (3125) *cubic centimeters* of filtrate: lastly, add the Syrup, and mix well.

29. DECOCTUM ALOES COMPOSITUM. *N. F.*

Compound Decoction of Aloes.

Extract of Aloes (U. S. P.)	10 Gm.
Myrrh	7.5 Gm.
Saffron	7.5 Gm.
Potassium Carbonate	5 Gm.
Extract of Glycyrrhiza, in powder	35 Gm.
Compound Tincture of Cardamom (U. S. P.)	250 Cc.
Water, a sufficient quantity	
To make	1000 Cc.

Reduce the Myrrh and Extract of Aloes to a coarse powder, mix this with the Potassium Carbonate and Extract of Liquorice in a suitable covered vessel, and pour on *six hundred* (600) *cubic centimeters* of Water; boil for five minutes, and add the Saffron. When cool, add the Compound Tincture of Cardamom, and allow the mixture to macerate for two hours. Then filter through flannel, and add enough Water to make the product measure *one thousand* (1000) *cubic centimeters.*

This preparation should be freshly made when wanted.

30. ELIXIR ACIDI SALICYLICI. *N. F.*

Elixir of Salicylic Acid.

Salicylic Acid	85 Gm.
Potassium Citrate	125 Gm.
Glycerin	500 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Potassium Citrate in the Glycerin with the aid of a gentle heat. Add the Salicylic Acid, and continue the heat until it is dissolved. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters.*

This Elixir should be freshly made when wanted.

Each fluidrachm contains 5 grains of Salicylic Acid.

31. ELIXIR ADJUVANS. *N. F.*

Adjuvant Elixir.

Sweet Orange Peel, recently dried	75 Gm.
Wild Cherry	150 Gm
Glycyrrhiza, Russian, peeled	300 Gm.
Coriander	40 Gm.
Caraway	40 Gm.
Syrup (U. S. P.)	1500 Cc.
Alcohol, Water, of each, a sufficient quantity	
To make	5000 Cc.

Grind the Wild Cherry to a moderately coarse (No. 40) powder, moisten it with *one hundred and fifty* (150) *cubic centimeters* of Water and set it aside for twelve hours. Reduce the other solids also to a moderately coarse (No. 40) powder, mix this intimately with the Wild Cherry, and having mixed *one* (1) *volume* of Alcohol with *two* (2) *volumes* of Water, moisten the powder with *one hundred and fifty* (150) *cubic centimeters* of the mixture, and pack tightly in a percolator. Then gradually pour menstruum on top until *thirty-five hundred* (3500) *cubic centimeters* of percolate are obtained. Mix this with *fifteen hundred* (1500) *cubic centimeters* of Syrup, and filter.

32. ELIXIR AMMONII BROMIDI. *N. F.*

Elixir of Ammonium Bromide.

Ammonium Bromide	85 Gm.
Citric Acid	4 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ammonium Bromide and the Citric Acid in about *five hundred* (500) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter, if necessary.

Each fluidrachm contains 5 grains of Ammonium Bromide.

33. ELIXIR AMMONII VALERIANATIS. *N. F.*

Elixir of Ammonium Valerianate.

Ammonium Valerianate	35 Gm.
Chloroform	0.8 Cc.
Tincture of Vanilla (U. S. P.)	16 Cc.
Compound Tincture of Cudbear (F. 419)	16 Cc.
Ammonia Water (U. S. P.), Aromatic Elixir (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Dissolve the Ammonium Valerianate in about *seventy-five* (75) *cubic centimeters* of Aromatic Elixir, in a graduated vessel, and add enough Ammonia Water, in drops, until a faint excess of it is perceptible in the liquid. Then add the Chloroform, Tincture of Vanilla, and Compound Tincture of Cudbear, and finally enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains 2 grains of Ammonium Valerianate.

Note.—Should the odor of valerianic acid become perceptible after the Elixir has been kept for some time, it may be overcome by slightly supersaturating with Ammonia Water.

34. ELIXIR AMMONII VALERIANATIS ET QUININÆ. *N. F.*

Elixir of Ammonium Valerianate and Quinine.

Quinine Hydrochlorate	4.25 Gm.
Elixir of Ammonium Valerianate (F. 33)	1000 Cc.

Dissolve the Quinine Hydrochlorate in the Elixir by agitation, and, if necessary, by occasionally immersing the bottle containing the ingredients in hot water, until solution has been effected. Finally filter.

Each fluidrachm contains ¼ grain of Quinine Hydrochlorate and 2 grains of Ammonium Valerianate.

35. ELIXIR ANISI. *N. F.*

Elixir of Anise.

Aniseed Cordial.

Anethol	3.5 Cc.
Oil of Fennel	0.5 Cc.
Spirit of Bitter Almond (U. S. P.)	12 Cc.
Deodorized Alcohol	240 Cc.
Syrup (U. S. P.)	625 Cc.
Water	125 Cc.
Magnesium Carbonate	15 Gm.

Mix the Anethol, the Oil, and the Spirit of Bitter Almond with the Deodorized Alcohol, add the Syrup and Water, and set the mixture aside for twelve hours. Then mix it intimately with the Magnesium Carbonate, and filter it through a wetted filter, returning the first portions of the filtrate until it runs through clear.

Note.—This Elixir is liable to become cloudy, from separation of essential oils, when it is exposed to a temperature lower than that at which it has been filtered. In general, it is recommended that it be cooled to, and filtered at a temperature of about 15° C. (59° F.). In the northern sections of this country, or in winter time, it should be cooled to a proportionately lower temperature, previous to filtration.

Anethol is the stearopten of oil of anise, and possesses a finer and purer aroma and taste than any commercial variety of oil of anise. If it cannot be readily obtained, the so-called Saxon oil of anise may be substituted for it. Oil of star-anise, which is usually supplied by dealers when "oil of anise" without specification is ordered, does not answer well for this purpose. The oil of fennel should be that from the seed ("sweet"), and not that from the chaff.

36. ELIXIR APII GRAVEOLENTIS COMPOSITUM. *N. F.*

Compound Elixir of Celery.

Fluid Extract of Celery Seed (F. 139)	62 Cc.
Fluid Extract of Coca (U. S. P.)	62 Cc.
Fluid Extract of Kola (F. 175)	62 Cc.
Fluid Extract of Viburnum Prunifolium (U. S. P.)	62 Cc.
Alcohol	125 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Alcohol with *two hundred and fifty* (250) *cubic centimeters* of Aromatic Elixir. To this add the Fluid Extract of Celery Seed in several portions, shaking after each addition, and afterwards the other Fluid Extracts. Finally add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, allow the mixture to stand twenty-four hours, and filter.

Note.—If this preparation is prescribed or quoted under its Latin title, it is recommended that the full title be given, so that the word "Apii" may not be mistaken for "Opii."

37. ELIXIR BISMUTHI. *N. F.*

Elixir of Bismuth.

Bismuth and Ammonium Citrate	35 Gm.
Water, hot	60 Cc.
Ammonia Water (U. S. P.), Aromatic Elixir (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Dissolve the Bismuth and Ammonium Citrate in the hot Water, allow the solution to stand until any undissolved matter has subsided; then decant the clear liquid, and add to the residue just enough Ammonia Water to dissolve it. Then mix it with the decanted portion and add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm represents 2 grains of Bismuth and Ammonium Citrate.

38. ELIXIR BUCHU. *N. F.*

Elixir of Buchu.

Fluid Extract of Buchu (U. S. P.)	125 Cc.
Alcohol	62 Cc.
Syrup (U. S. P.)	62 Cc.
Magnesium Carbonate	15 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the fluid Extract of Buchu with the Alcohol, then add *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir, and the Syrup. Incorporate with it the Magnesium Carbonate, and filter. Finally, pass enough Aromatic Elixir through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents about 7½ grains of Buchu.

39. ELIXIR BUCHU COMPOSITUM. *N. F.*

Compound Elixir of Buchu.

Compound Fluid Extract of Buchu (F. 144)	250 Cc.
Alcohol	62 Cc.
Syrup (U. S. P.)	62 Cc.
Magnesium Carbonate	15 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Compound Fluid Extract of Buchu with the Alcohol, then add *five hundred* (500) *cubic centimeters* of Aromatic Elixir, and the Syrup. Incorporate with it the Magnesium Carbonate, and filter. Finally, pass enough Aromatic Elixir through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 15 *minims of Compound Fluid Extract of Buchu.*

40. ELIXIR BUCHU ET POTASSII ACETATIS. *N. F.*

Elixir of Buchu and Potassium Acetate.

Potassium Acetate	85 Gm.
Elixir of Buchu (F. 38), a sufficient quantity	
To make	1000 Cc.

Dissolve the Potassium Acetate in about *seven hundred and fifty* (750) *cubic centimeters* of Elixir of Buchu, filter, if necessary, and add enough Elixir of Buchu to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 5 grains of Potassium Acetate and about 7 grains of Buchu.

41. ELIXIR CAFFEINÆ. *N. F.*

Elixir of Caffeine.

Caffeine	17.5 Gm.
Diluted Hydrobromic Acid (U. S. P.)	4 Cc.
Syrup of Coffee (F. 367)	250 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Rub the Caffeine, in a mortar, with the Diluted Hydrobromic Acid and about *one hundred and twenty-five* (125) *cubic centimeters* of Aromatic Elixir, until solution is effected. Then add the Syrup of Coffee, and lastly, enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters.* Filter, if necessary.

Each fluidrachm contains 1 grain of Caffeine.

42. ELIXIR CALCII BROMIDI. *N. F.*

Elixir of Calcium Bromide.

Calcium Bromide	85 Gm.
Citric Acid	4 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Calcium Bromide and the Citric Acid in about *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters,* and filter, if necessary.

Each fluidrachm contains 5 grains of Calcium Bromide.

43. ELIXIR CALCII HYPOPHOSPHITIS. *N. F.*

Elixir of Calcium Hypophosphite.

Calcium Hypophosphite	35 Gm.
Citric Acid	4 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Calcium Hypophosphite in *nine hundred* (900) *cubic centimeters* of Aromatic Elixir, and filter. Dissolve the Citric Acid in the filtrate and pass enough Aromatic Elixir through the filter to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains 2 grains of Calcium Hypophosphite.

44. ELIXIR CALCII LACTOPHOSPHATIS. *N. F.*

Elixir of Calcium Lactophosphate.

Calcium Lactate	17.5 Gm.
Phosphoric Acid (U. S. P., 85%)	8 Cc.
Water	60 Cc.
Syrup (U. S. P.)	60 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Calcium Lactate with the Phosphoric Acid, the Water, and the Syrup, until the salt is dissolved. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters,* and filter.

Each fluidrachm represents 1 grain of Calcium Lactate, or about 1¼ grains of so-called Calcium Lactophosphate.

45. ELIXIR CATHARTICUM COMPOSITUM. *N. F.*

Compound Cathartic Elixir.

Fluid Extract of Senna (U. S. P.)	125 Cc.
Fluid Extract of Podophyllum (U. S. P.)	62 Cc.
Fluid Extract of Leptandra (U. S. P.)	50 Cc.
Fluid Extract of Jalap (F. 162)	50 Cc.
Potassium and Sodium Tartrate	125 Gm.
Sodium Bicarbonate	16 Gm.
Compound Elixir of Taraxacum (F. 111)	250 Cc.
Elixir of Glycyrrhiza (F. 76), a sufficient quantity	
To make	1000 Cc.

Mix the fluid extracts with the Compound Elixir of Taraxacum; in the mixture, dissolve the salts by agitation, and add enough Elixir of Glycyrrhiza to make *one thousand* (1000) *cubic centimeters.*

The product should not be filtered, and should be shaken up whenever any of it is dispensed.

The average dose for an adult is 2 fluidrachms.

46. ELIXIR CHLOROFORMI COMPOSITUM. *N. F.*

Compound Elixir of Chloroform.

Chloroform	190 Cc.
Tincture of Opium (U. S. P.)	190 Cc.
Spirit of Camphor (U. S. P.)	190 Cc.
Aromatic Spirit of Ammonia (U. S. P.)	190 Cc.
Alcohol	235 Cc.
Oil of Cinnamon (Cassia)	5 Cc.

Mix the Chloroform with the Alcohol, then add the Oil of Cinnamon, Aromatic Spirit of Ammonia, Spirit of Camphor, and Tincture of Opium. Allow the mixture to stand a few hours, and filter in a well-covered funnel.

Each fluidrachm represents about 1 grain of Opium and 11 minims of Chloroform.

Note.—This preparation is called Chloroform Paregoric in some sections of the country. It is recommended that this title be abandoned, to prevent confusion with the official Paregoric or *Tinctura Opii Camphorata.*

47. ELIXIR CINCHONÆ. *N. F.*

Elixir of Cinchona.

Elixir of Calisaya.

Tincture of Cinchona (U. S. P.)	150 Cc.
Syrup (U. S. P.)	125 Cc.
Glycerin	125 Cc.
Aromatic Elixir (U. S. P.)	600 Cc.

Mix the liquids, allow to stand as long as convenient, and filter through a wetted filter.

Each fluidounce represents about fourteen (14) *grains of Yellow Cinchona.*

48. ELIXIR CINCHONÆ DETANNATUM. *N. F.*

Detannated Elixir of Cinchona.

Detannated Elixir of Calisaya.

Detannated Tincture of Cinchona (F. 403)	150 Cc.
Syrup (U. S. P.)	125 Cc.
Glycerin	125 Cc.
Aromatic Elixir (U. S. P.)	600 Cc.

Mix the Liquids, and filter, if necessary.

Each fluidounce represents about fourteen (14) *grains of Yellow Cinchona.*

Note.—This preparation may be used when *Elixir Cinchonæ* is directed in combination with preparations of Iron, but may be replaced by *Compound Elixir of Quinine* (F. 98), colored by the addition of *fifteen* (15) *cubic centimeters* of Compound Tincture of Cudbear (F. 419) to *one thousand* (1000) *cubic centimeters.*

49. ELIXIR CINCHONÆ ET HYPOPHOSPHITUM. *N. F.*

Elixir of Cinchona and Hypophosphites.

Elixir of Calisaya and Hypophosphites.

Calcium Hypophosphite	17.5	Gm.
Sodium Hypophosphite	17.5	Gm.
Citric Acid	4	Gm.
Water	125	Cc.
Elixir of Cinchona (F. 47), a sufficient quantity		
To make	1000	Cc.

Dissolve the Hypophosphites and the Citric Acid in the Water, add enough Elixir of Cinchona to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 1 grain, each, of the Hypophosphites of Calcium and Sodium.

50. ELIXIR CINCHONÆ ET FERRI. *N. F.*

Elixir of Cinchona and Iron.

Elixir of Calisaya and Iron. Ferrated Elixir of Calisaya.

Soluble Ferric Phosphate (U. S. P.)	35	Gm.
Water, boiling	60	Cc.
Compound Elixir of Quinine (F. 98), a sufficient quantity		
To make	1000	Cc.

Dissolve the Soluble Ferric Phosphate in the boiling Water, then add enough Compound Elixir of Quinine to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 2 grains of Soluble Ferric Phosphate.

51. ELIXIR CINCHONÆ, FERRI, BISMUTHI, ET STRYCHNINÆ. *N. F.*

Elixir of Cinchona, Iron, Bismuth, and Strychnine.

Elixir of Calisaya, Iron, Bismuth, and Strychnine.

Strychnine Sulphate	0.175	Gm.
Water, hot	10	Cc.
Elixir of Cinchona, Iron, and Bismuth (F. 52)	990	Cc.

Dissolve the Strychnine Sulphate in the hot Water, add the Elixir of Cinchona, Iron, and Bismuth, and filter, if necessary.

52. ELIXIR CINCHONÆ, FERRI, ET BISMUTHI. *N. F.*

Elixir of Cinchona, Iron, and Bismuth.

Elixir of Calisaya, Iron, and Bismuth.

Bismuth and Ammonium Citrate	17.5	Gm.
Water, hot	30	Cc.
Ammonia Water (U. S. P.) a sufficient quantity.		
Elixir of Cinchona and Iron (F. 50), a sufficient quantity		
To make	1000	Cc.

Dissolve the Bismuth and Ammonium Citrate in the hot Water, allow the solution to stand until any undissolved matter has subsided; then decant the clear liquid, and add to the residue enough Ammonia Water to dissolve it, carefully avoiding an excess. Then mix the solution with enough Elixir of Cinchona and Iron to make *one thousand* (1000) *cubic centimeters.* Let the mixture stand twenty-four hours, if convenient, and filter.

Each fluidrachm contains 1 grain of Bismuth and Ammonium Citrate, and nearly 2 grains of Ferric Phosphate.

53. ELIXIR CINCHONÆ, FERRI, ET CALCII LACTOPHOSPHATIS. *N. F.*

Elixir of Cinchona, Iron, and Calcium Lactophosphate.

Elixir of Calisaya, Iron, and Calcium Lactophosphate.

Calcium Lactate	8.5	Gm.
Phosphoric Acid (U. S. P., 85 %)	4	Cc.
Ammonia Water (U. S. P.)	32	Cc.
Citric Acid	16	Gm.
Elixir of Cinchona and Iron (F. 50), a sufficient quantity		
To make	1000	Cc.

Dissolve the Calcium Lactate in *four hundred and fifty* (450) *cubic centimeters* of Elixir of Cinchona and Iron, with the aid of the Phosphoric Acid. Then add the Citric Acid, and, when this is dissolved, the Ammonia Water. Finally add enough Elixir of Cinchona and Iron to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains ½ grain of Calcium Lactate (or about ⅔ grain of so-called Calcium Lactophosphate), and nearly 2 grains of Ferric Phosphate.

54. ELIXIR CINCHONÆ, FERRI, ET PEPSINI. *N. F.*

Elixir of Cinchona, Iron, and Pepsin.

Elixir of Calisaya, Iron, and Pepsin.

Pepsin (U. S. P.)	17.5	Gm.
Hydrochloric Acid (U. S. P.)	4	Cc.
Water	175	Cc.
Elixir of Cinchona and Iron (F. 50), a sufficient quantity		
To make	1000	Cc.

Dissolve the Pepsin in the Water mixed with the Hydrochloric Acid; then add enough Elixir of Cinchona and Iron to make *one thousand* (1000) *cubic centimeters.* Let the mixture stand a few days, if convenient, and filter.

Each fluidrachm represents 1 grain of Pepsin and about 1½ grains of Ferric Phosphate.

55. ELIXIR CINCHONÆ, FERRI, ET STRYCHNINÆ. *N. F.*

Elixir of Cinchona, Iron, and Strychnine.

Elixir of Calisaya, Iron, and Strychnine.

Strychnine Sulphate	0.175	Gm.
Water	15	Cc.
Elixir of Cinchona and Iron (F. 50), a sufficient quantity		
To make	1000	Cc.

Dissolve the Strychnine Sulphate in the Water and add enough Elixir of Cinchona and Iron to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains $\frac{1}{100}$ grain of Strychnine Sulphate, and about 2 grains of Ferric Phosphate.

56. ELIXIR CINCHONÆ, PEPSINI, ET STRYCHNINÆ. *N. F.*

Elixir of Cinchona, Pepsin, and Strychnine.

Elixir of Calisaya, Pepsin, and Strychnine.

Quinine Sulphate	2	Gm.
Cinchonine Sulphate	1	Gm.
Strychnine Sulphate	0.175	Gm.
Elixir of Pepsin (F. 88), a sufficient quantity		
To make	1000	Cc.

Dissolve the alkaloidal salts in the Elixir, and filter, if necessary.

Each fluidrachm represents small quantities of Cinchona Alkaloids, $\frac{1}{100}$ grain of Strychnine Sulphate, and 1 grain of Pepsin.

57. ELIXIR CORYDALIS COMPOSITUM. *N. F.*

Compound Elixir of Corydalis.

Fluid Extract of Corydalis (F. 154)	60 Cc.
Fluid Extract of Stillingia (U. S. P.)	60 Cc.
Fluid Extract of Xanthoxylum (U. S. P.)	30 Cc.
Fluid Extract of Iris (U. S. P.)	90 Cc.
Alcohol	125 Cc.
Potassium Iodide	50 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Alcohol with the Fluid Extracts, dissolve the Potassium Iodide in the mixture, and add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Let the mixture stand a few days, if convenient, and filter.

Each fluidrachm contains 3 grains of Potassium Iodide, and small quantities of the several Fluid Extracts.

58. ELIXIR CURASSAO. *N. F.*

Elixir of Curaçao.

Curaçao Cordial.

Spirit of Curaçao (F. 348)	16 Cc.
Orris Root, in fine powder	4 Gm.
Deodorized Alcohol	250 Cc.
Citric Acid	7 Gm.
Syrup (U. S. P.)	500 Cc.
Magnesium Carbonate	15 Gm.
Water, a sufficient quantity	
To make	1000 Cc.

Mix the Spirit of Curaçao with the Alcohol, add the Orris Root, the Magnesium Carbonate, and *one hundred and eighty-five* (185) *cubic centimeters* of Water. Allow the mixture to stand twelve hours, occasionally agitating; then pour it on a wetted filter, returning the first portions of the filtrate until it runs through clear, and pass enough Water through the filter to make the filtrate measure *five hundred* (500) *cubic centimeters*. In this dissolve the Citric Acid, and finally add the Syrup.

59. ELIXIR DIGESTIVUM COMPOSITUM. *N. F.*

Compound Digestive Elixir.

Compound Elixir of Pepsin.

Pepsin (U. S. P.)	10 Gm.
Pancreatin (U. S. P.)	1 Gm.
Diastase	1 Gm.
Lactic Acid	3 Gm.
Hydrochloric Acid (U. S. P.)	6 Cc.
Glycerin	250 Cc.
Water	125 Cc.
Tincture of Cudbear (F. 418)	15 Cc.
Purified Talcum (F. 395)	15 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Acids with the Glycerin and Water, add the Pepsin, Pancreatin, and Diastase to this mixture, and macerate with occasional shaking, until solution is apparently effected. Then add the Tincture of Cudbear and enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Incorporate the Purified Talcum thoroughly with the mixture, and filter.

Note.—The best commercial variety of Diastase, capable of converting the largest amount of starch into dextrin and glucose, should be used for this preparation.

60. ELIXIR ERIODICTYI AROMATICUM. *N. F.*

Aromatic Elixir of Eriodictyon.

Aromatic Elixir of Yerba Santa; Elixir Corrigens.

Fluid Extract of Eriodictyon (U. S. P.)	62.5 Cc.
Syrup (U. S. P.)	500 Cc.
Pumice, in fine powder	30 Gm.
Magnesium Carbonate	11 Gm.
Compound Elixir of Taraxacum (F. 111), a sufficient quantity	
To make	1000 Cc.

Mix *four hundred and fifty* (450) *cubic centimeters* of Compound Elixir of Taraxacum with the Syrup and Pumice, then add the Fluid Extract, and mix the whole thoroughly by agitation. Shake the mixture occasionally during two hours, then allow it to settle, and carefully decant the liquid into a funnel, the neck of which contains a small pellet of absorbent cotton. Afterwards add the dregs and allow them to drain. To the filtrate add the Magnesium Carbonate, and shake occasionally during several hours. Let the mixture stand at rest during twelve hours, if convenient, then decant the liquid and filter it through paper. To the filtrate add enough Compound Elixir of Taraxacum, if necessary, to make *one thousand* (1000) *cubic centimeters*.

61. ELIXIR ERYTHROXYLI. *N. F.*

Elixir of Erythroxylon.

Elixir of Coca.

Fluid Extract of Coca (U. S. P.)	125 Cc.
Alcohol	62.5 Cc.
Syrup (U. S. P.)	125 Cc.
Tincture of Vanilla (U. S. P.)	16 Cc.
Purified Talcum (F. 395)	15 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Mix the Fluid Extract with the Alcohol, the Syrup, and *six hundred and fifty* (650) *cubic centimeters* of Aromatic Elixir, add the Purified Talcum and incorporate the latter thoroughly. Let the mixture stand during forty-eight hours, if convenient, shaking occasionally; then filter, add the Tincture of Vanilla to the filtrate, and pass enough Aromatic Elixir through the filter to make the product measure *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 7½ grains of Erythroxylon (Coca).

62. ELIXIR ERYTHROXYLI ET GUARANÆ. *N. F.*

Elixir of Erythroxylon and Guarana.

Elixir of Coca and Guarana.

Fluid Extract of Coca (U. S. P.)	125 Cc.
Fluid Extract of Guarana (U. S. P.)	125 Cc.
Purified Talcum (F. 395)	15 Gm.
Compound Elixir of Taraxacum (F. 111)	750 Cc.

Mix the liquids, and thoroughly incorporate the Purified Talcum with the mixture. Let it stand during forty-eight hours, if convenient, occasionally agitating, then filter.

Each fluidrachm represents 7½ grains each of Erythroxylon (Coca) and Guarana.

63. ELIXIR EUCALYPTI. *N. F.*

Elixir of Eucalyptus.

Fluid Extract of Eucalyptus (U. S. P.)	125 Cc.
Alcohol	125 Cc.
Magnesium Carbonate	16 Gm.
Syrup of Coffee (F. 367)	375 Cc.
Compound Elixir of Taraxacum (F. 111)	375 Cc.

Mix the Fluid Extract with the Alcohol, then add the other ingredients, shake the mixture occasionally during forty-eight hours, and filter.

Each fluidrachm represents 7½ grains of Eucalyptus.

64. ELIXIR EUONYMI. *N. F.*

Elixir of Euonymus.

Elixir of Wahoo.

Fluid Extract of Euonymus (U. S. P.)	150 Cc.
Water	125 Cc.
Syrup of Coffee (F. 367)	125 Cc.
Compound Elixir of Taraxacum (F. 111)	600 Cc.

Mix them, let the mixture stand forty-eight hours, and filter.

Each fluidrachm represents about 9½ grains of Euonymus.

65. ELIXIR FERRI HYPOPHOSPHITIS. *N. F.*

Elixir of Ferric Hypophosphite.

Solution of Ferric Hypophosphite (F. 219)	100 Cc.
Aromatic Elixir (U. S. P.)	900 Cc.

Mix, allow the mixture to stand a few days in a cool place, and filter if necessary.

Each fluidrachm contains 1 grain of Ferric Hypophosphite.

66. ELIXIR FERRI LACTATIS. *N. F.*

Elixir of Ferrous Lactate.

Ferrous Lactate, in crusts	17.5 Gm.
Potassium Citrate	52.5 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Ferrous Lactate with the Potassium Citrate and about *two hundred and fifty* (250) *cubic centimeters* of Aromatic Elixir, gradually added, until solution has been effected. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 1 grain of Ferrous Lactate.

67. ELIXIR FERRI PHOSPHATIS. *N. F.*

Elixir of Ferric Phosphate.

Ferric Phosphate (U. S. P.)	35 Gm.
Water	60 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferric Phosphate in the Water with the aid of heat; then mix this solution with a sufficient quantity of Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains 2 grains of Ferric Phosphate.

68. ELIXIR FERRI PHOSPHATIS, CINCHONIDINÆ, ET STRYCHNINÆ. *N. F.*

Elixir of Ferric Phosphate, Cinchonidine, and Strychnine.

Ferric Phosphate (U. S. P.)	35 Gm.
Potassium Citrate	4.5 Gm.
Cinchonidine Sulphate	8.5 Gm.
Strychnine Sulphate	0.175 Gm.
Alcohol	65 Cc.
Water	50 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferric Phosphate and Potassium Citrate in the Water, using heat, if necessary. To *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir, contained in a bottle, add the Alcohol, and afterwards the alkaloidal salts, and agitate until the latter are dissolved, or nearly so. Then mix the two solutions, and, having shaken the mixture, add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Finally filter.

Each fluidrachm contains 2 grains of Ferric Phosphate, ½ grain of Cinchonidine Sulphate, and $\frac{1}{100}$ grain of Strychnine Sulphate.

69. ELIXIR FERRI PHOSPHATIS, QUININÆ, ET STRYCHNINÆ. *N. F.*

Elixir of Ferric Phosphate, Quinine, and Strychnine.

Ferric Phosphate (U. S. P.)	17.5 Gm.
Quinine (alkaloid)	8.75 Gm.
Strychnine (alkaloid)	0.275 Gm.
Alcohol	130 Cc.
Water	50 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the alkaloids in the Alcohol and add *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir, then dissolve the Ferric Phosphate in the Water, using heat, if necessary, and add to the previous mixture. Finally, add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains 1 grain of Ferric Phosphate, ½ grain of Quinine, and $\frac{1}{64}$ grain of Strychnine.

70. ELIXIR FERRI PYROPHOSPHATIS. *N. F.*

Elixir of Ferric Pyrophosphate.

Ferric Pyrophosphate (U. S. P.)	35 Gm.
Water	60 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferric Pyrophosphate in the Water, and add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains 2 grains of Ferric Pyrophosphate.

71. ELIXIR FERRI, QUININÆ, ET STRYCHNINÆ. *N. F.*

Elixir of Iron, Quinine, and Strychnine.

Tincture of Ferric Citro-Chloride (F. 407)	125 Cc.
Quinine Hydrochlorate	8.5 Gm.
Strychnine Sulphate	0.175 Gm.
Alcohol	30 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the alkaloidal salts in about *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir, then add the Tincture and the Alcohol, and, finally, enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm represents about 1 grain of Ferric Chloride, ½ grain of Quinine Hydrochlorate, and $\frac{1}{100}$ grain of Strychnine Sulphate.

72. ELIXIR FRANGULÆ. *N. F.*

Elixir of Frangula.

Elixir of Buckthorn.

Fluid Extract of Frangula (U. S. P.)	250 Cc.
Alcohol	60 Cc.
Compound Elixir of Taraxacum (F. 111)	250 Cc.
Aromatic Elixir (U. S. P.)	440 Cc.

Mix them, allow the mixture to stand during forty-eight hours, if convenient, and filter.

Each fluidrachm represents 15 *grains of Frangula.*

73. ELIXIR GENTIANÆ. *N. F.*

Elixir of Gentian.

Fluid Extract of Gentian (U. S. P.)	35 Cc.
Compound Spirit of Cardamom (F. 347)	25 Cc.
Solution of Ferric Sulphate (U. S. P.)	25 Cc.
Ammonia Water (U. S. P.)	28 Cc.
Alcohol,	
Water,	
Aromatic Elixir (U. S. P.), of each, a sufficient quantity	
To make	1000 Cc.

Dilute the Solution of Ferric Sulphate with *two hundred and fifty* (250) *cubic centimeters* of cold Water, and add it, constantly stirring, to the Ammonia Water, previously diluted with an equal volume of cold Water. Collect the precipitate on a well-wetted muslin strainer, allow it to drain completely, return it to the vessel, mix it intimately with *two hundred and fifty* (250) *cubic centimeters* of Water, and again drain. Repeat this operation once more with the same quantity of Water. When the precipitate has been completely drained for the third time, fold the strainer, and press it gently so as to remove the Water as completely as possible without loss of magma; then remove the magma into a tared bottle, and ascertain its weight. Now add to the magma *one-fifth* ($\frac{1}{5}$) of its weight of Alcohol, the Fluid Extract, the Compound Spirit, and *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir, and shake the mixture occasionally during twenty-four hours. Filter through paper, and pass enough Aromatic Elixir through the filter to make the product measure *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents about 2 *grains of Gentian.*

74. ELIXIR GENTIANÆ CUM TINCTURA FERRI CHLORIDI. *N. F.*

Elixir of Gentian with Tincture of Ferric Chloride.

Tincture of Ferric Citro-Chloride (F. 407)	100 Cc.
Elixir of Gentian (F. 73)	900 Cc.

Mix and filter, if necessary.

Each fluidrachm represents about $\frac{3}{4}$ *grain of Ferric Chloride and nearly* 2 *grains of Gentian.*

75. ELIXIR GENTIANÆ ET FERRI PHOSPHATIS. *N. F.*

Elixir of Gentian and Ferric Phosphate.

Elixir Gentianæ Ferratum. Ferrated Elixir of Gentian. Ferrophosphated Elixir of Gentian.

Ferric Phosphate (U. S. P.)	17.5 Gm.
Water	35 Cc.
Elixir of Gentian (F. 73), a sufficient quantity	
To make	1000 Cc.

Dissolve the Ferric Phosphate in the Water with the aid of heat, and add enough Elixir of Gentian to make *one thousand* (1000) *cubic centimeters.* Filter, if necessary.

Each fluidrachm represents 1 *grain of Ferric Phosphate, and nearly* 2 *grains of Gentian.*

76. ELIXIR GLYCYRRHIZÆ. *N. F.*

Elixir of Glycyrrhiza.

Elixir of Liquorice.

Fluid Extract of Glycyrrhiza (U. S. P.)	125 Cc.
Aromatic Elixir (U. S. P)	875 Cc.

Mix and filter, if necessary.

77. ELIXIR GLYCYRRHIZÆ AROMATICUM. *N. F.*

Aromatic Elixir of Glycyrrhiza.

Aromatic Elixir of Liquorice.

Fluid Extract of Glycyrrhiza (U. S. P.)	125 Cc.
Oil of Cloves	0.4 Cc.
Oil of Cinnamon (Ceylon)	0.4 Cc.
Oil of Nutmegs	0.25 Cc.
Oil of Fennel	0.75 Cc.
Magnesium Carbonate	15 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Oils with the Magnesium Carbonate, and gradually add *eight hundred and seventy-five* (875) *cubic centimeters* of Aromatic Elixir. Shake occasionally during an hour, filter, and pass enough Aromatic Elixir through the filter to make *eight hundred and seventy-five* (875) *cubic centimeters* of filtrate. Add the fluid extract to the filtrate, mix, and filter, if necessary.

78. ELIXIR GRINDELIÆ. *N. F.*

Elixir of Grindelia.

Fluid Extract of Grindelia (U. S. P.)	65 Cc.
Compound Spirit of Orange (U. S. P.)	10 Cc.
Deodorized Alcohol	115 Cc.
Compound Elixir of Taraxacum (F. 111)	810 Cc.

Mix them, allow the mixture to stand a few days, if convenient, then filter.

Each fluidounce represents 30 *grains of Grindelia.*

79. ELIXIR GUARANÆ. *N. F.*

Elixir of Guarana.

Fluid Extract of Guarana (U. S. P.)	200 Cc.
Aromatic Elixir (U. S. P.)	200 Cc.
Compound Elixir of Taraxacum (F. 111)	600 Cc.

Mix them; allow the mixture to stand during forty-eight hours, if convenient, and filter.

Each fluidrachm represents about 12 *grains of Guarana.*

80. ELIXIR HUMULI. *N. F.*

Elixir of Humulus.

Elixir of Hops.

Fluid Extract of Hops (F. 160)	125 Cc.
Magnesium Carbonate	15 Gm.
Tincture of Vanilla (U. S. P.)	30 Cc.
Compound Elixir of Taraxacum (F. 111)	125 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Fluid Extract of Hops with the Magnesium Carbonate, then gradually add the Compound Elixir of Taraxacum, Tincture of Vanilla, and enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters.* Allow the mixture to stand several days, if convenient, occasionally agitating; then filter.

Each fluidrachm represents $7\frac{1}{2}$ *grains of Humulus (Hops).*

81. ELIXIR HYPOPHOSPHITUM. *N. F.*

Elixir of Hypophosphites.

Calcium Hypophosphite	52.5 Gm.
Sodium Hypophosphite	17.5 Gm.
Potassium Hypophosphite	17.5 Gm.
Citric Acid	4 Gm.
Water	250 Cc.
Glycerin	30 Cc.

Compound Spirit of Cardamom (F. 347)	30	Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Hypophosphites and the Citric Acid in the Water; then add the Glycerin, Compound Spirit of Cardamom, and enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains 3 grains of Calcium Hypophosphite and 1 grain, each, of Sodium and Potassium Hypophosphites.

82. ELIXIR HYPOPHOSPHITUM CUM FERRO. *N. F.*

Elixir of Hypophosphites with Iron.

Calcium Hypophosphite	25	Gm.
Sodium Hypophosphite	17.5	Gm.
Potassium Hypophosphite	8.5	Gm.
Ferrous Sulphate, in clear crystals	13	Gm.
Citric Acid	4	Gm.
Water	250	Cc.
Syrup (U. S. P.)	250	Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Hypophosphites in *one hundred and seventy-five* (175) *cubic centimeters* of Water, and add the Syrup. Dissolve the Ferrous Sulphate in the remainder of the Water, and mix this with the other solution. Then add *three hundred and fifty* (350) *cubic centimeters* of Aromatic Elixir, set the mixture aside, in a cold place, for twelve hours, and filter from the deposited calcium sulphate. Finally dissolve the Citric Acid in the filtrate, and pass enough Aromatic Elixir through the filter to make *one thousand* (1000) *cubic centimeters*.

Each fluidrachm contains about ½ grain of Ferrous Hypophosphite, about 1 grain, each, of Calcium and Sodium Hypophosphites, and ½ grain of Potassium Hypophosphite.

83. ELIXIR LITHII BROMIDI. *N. F.*

Elixir of Lithium Bromide.

Lithium Bromide	85	Gm.
Citric Acid	4	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the solids in about *nine hundred* (900) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains about 5 grains of Lithium Bromide.

84. ELIXIR LITHII CITRATIS. *N. F.*

Elixir of Lithium Citrate.

Lithium Citrate	85	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Lithium Citrate in about *nine hundred* (900) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 5 grains of Lithium Citrate.

85. ELIXIR LITHII SALICYLATIS. *N. F.*

Elixir of Lithium Salicylate.

Lithium Salicylate	85	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Lithium Salicylate in about *nine hundred* (900) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm contains 5 grains of Lithium Salicylate.

86. ELIXIR MALTI ET FERRI. *N. F.*

Elixir of Malt and Iron.

Extract of Malt	250	Cc.
Ferric Phosphate (U. S. P.)	17.5	Gm.
Water	30	Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Ferric Phosphate in the Water by the aid of heat, mix the solution with the Extract of Malt previously introduced into a graduated bottle, and add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Set the mixture aside for twenty-four hours, and filter.

Each fluidrachm represents 1 grain of Ferric Phosphate and 15 minims of Extract of Malt.

Note.—Extract of Malt, most suitable for this preparation, should have about the consistence of Balsam of Peru at a temperature of about 15° C. (59° F.).

87. ELIXIR PARALDEHYDI. *N. F.*

Elixir of Paraldehyde.

(25 per cent.)

Paraldehyde	250	Cc.
Glycerin	125	Cc.
Alcohol	315	Cc.
Tincture of Cardamom (U. S. P.)	17.5	Cc.
Oil of Orange	2	Cc.
Oil of Cinnamon	2	Cc.
Compound Tincture of Cudbear (F. 419)	15	Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Mix the ingredients in the order given, and filter, if necessary.

Each teaspoonful contains about fifteen (15) *minims of Paraldehyde.*

88. ELIXIR PEPSINI. *N. F.*

Elixir of Pepsin.

Pepsin (U. S. P.)	17.5	Gm.
Hydrochloric Acid (U. S. P.)	4	Cc.
Glycerin	125	Cc.
Compound Elixir of Taraxacum (F. 111)	65	Cc.
Alcohol	175	Cc.
Purified Talcum (F. 395)	15	Gm.
Sugar	250	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Mix the Pepsin with *three hundred and fifty* (350) *cubic centimeters* of Water, add the Glycerin and Acid, and agitate until solution has been effected. Then add the Compound Elixir of Taraxacum, Alcohol, and the Purified Talcum, and mix thoroughly. Set the mixture aside for a few hours, occasionally agitating. Then filter it through a wetted filter, dissolve the Sugar in the filtrate, and pass enough water through the filter to make the whole product measure *one thousand* (1000) *cubic centimeters*.

Each fluidrachm represents 1 grain of Pepsin.

89. ELIXIR PEPSINI, BISMUTHI, ET STRYCHNINÆ. *N. F.*

Elixir of Pepsin, Bismuth, and Strychnine.

Strychnine Sulphate	0.175	Gm.
Elixir of Pepsin and Bismuth (F. 90)	1000	Cc.

Dissolve the Strychnine Sulphate in the Elixir.

Each fluidrachm represents $\frac{1}{100}$ *grain of Strychnine Sulphate,* 1 *grain of Pepsin, and* 2 *grains of Bismuth and Ammonium Citrate.*

90. ELIXIR PEPSINI ET BISMUTHI. *N. F.*

Elixir of Pepsin and Bismuth.

Pepsin (U. S. P.)	17.5	Gm.
Bismuth and Ammonium Citrate	35	Gm.
Ammonia Water (U. S. P.)	a sufficient quantity.	
Glycerin	125	Cc.
Alcohol	175	Cc.
Syrup (U. S. P.)	250	Cc.
Compound Elixir of Taraxacum (F. 111)	65	Cc.
Purified Talcum (F. 395)	15	Gm.
Water, a sufficient quantity		
To make	1000	Cc.

Dissolve the Pepsin in *two hundred and fifty* (250) *cubic centimeters* of Water. Dissolve the Bismuth and Ammonium Citrate in *sixty* (60) *cubic centimeters* of warm Water, allow the solution to stand until clear, if necessary; then decant the clear liquid, and add to the residue just enough Ammonia Water to dissolve it, carefully avoiding an excess. Then mix the two solutions, and add the Glycerin, Compound Elixir of Taraxacum, and Alcohol. Thoroughly incorporate the Purified Talcum with the mixture, filter it through a wetted filter, and pass enough Water through the filter to make the filtrate measure *seven hundred and fifty* (750) *cubic centimeters.* To this add the Syrup.

Each fluidrachm represents 1 *grain of Pepsin and* 2 *grains of Bismuth and Ammonium Citrate.*

91. ELIXIR PEPSINI ET FERRI. *N. F.*

Elixir of Pepsin and Iron.

Tincture of Ferric Citro-Chloride (F. 407)	75	Cc.
Elixir of Pepsin (F. 88)	925	Cc.

Mix, and filter, if necessary.

Each fluidrachm represents about $\frac{1}{2}$ *grain of Ferric Chloride and nearly* 1 *grain of Pepsin.*

92. ELIXIR PHOSPHORI ET NUCIS VOMICÆ. *N. F.*

Elixir of Phosphorus and Nux Vomica.

Tincture of Nux Vomica (U. S. P.)	35	Cc.
Elixir of Phosphorus (U. S. P.)	965	Cc.

Mix them. This preparation should be freshly made when wanted for use.

Each fluidrachm represents 2 *minims of Tincture of Nux Vomica and nearly* $\frac{1}{60}$ *grain of Phosphorus.*

93. ELIXIR PICIS COMPOSITUM. *N. F.*

Compound Elixir of Tar.

Syrup of Wild Cherry (U. S. P.)	200	Cc.
Syrup of Tolu (U. S. P.)	200	Cc.
Morphine Sulphate	0.35	Gm.
Methylic Alcohol	50	Cc.
Water, Wine of Tar (F. 451), of each, a sufficient quantity		
To make	1000	Cc.

Dissolve the Morphine Sulphate in about *eight* (8) *cubic centimeters* of hot Water, and add the solution to the two Syrups previously mixed. Then add the Methylic Alcohol and enough Wine of Tar to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm contains about $\frac{1}{60}$ *grain of Morphine Sulphate.*

94. ELIXIR PILOCARPI.

Elixir of Pilocarpus.

Elixir of Jaborandi.

Fluid Extract of Pilocarpus (U. S. P.)	65	Cc.
Syrup of Coffee (F. 367)	200	Cc.
Tincture of Vanilla (U. S. P.)	35	Cc.
Compound Elixir of Taraxacum (F. 111)	700	Cc.

Mix them. Allow the mixture to stand during four days, if convenient, and filter.

Each fluidrachm represents $3\frac{3}{4}$ *grains of Pilocarpus.*

95. ELIXIR POTASSII ACETATIS. *N. F.*

Elixir of Potassium Acetate.

Potassium Acetate	85	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Potassium Acetate in *nine hundred* (900) *cubic centimeters* of Aromatic Elixir, then add enough of the latter to make *one thousand* (1000) *cubic centimeters.* Filter, if necessary.

Each fluidrachm contains about 5 *grains of Potassium Acetate.*

96. ELIXIR POTASSII ACETATIS ET JUNIPERI. *N. F.*

Elixir of Potassium Acetate and Juniper.

Potassium Acetate	85	Gm.
Fluid Extract of Juniper (F. 164)	125	Cc.
Magnesium Carbonate	15	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Triturate the Fluid Extract of Juniper with the Magnesium Carbonate, then add *seven hundred and fifty* (750) *cubic centimeters* of Aromatic Elixir in which the Potassium Acetate has previously been dissolved. Filter, and add enough Aromatic Elixir, through the filter, to make *one thousand* (1000) *cubic centimeters.*

Each fluidrachm represents 5 *grains of Potassium Acetate and* $7\frac{1}{2}$ *grains of Juniper.*

97. ELIXIR POTASSII BROMIDI. *N. F.*

Elixir of Potassium Bromide.

Potassium Bromide	175	Gm.
Citric Acid	4	Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity		
To make	1000	Cc.

Dissolve the Potassium Bromide and the Citric Acid in about *eight hundred* (800) *cubic centimeters* of Aromatic Elixir by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters,* and filter.

Each fluidrachm contains 10 *grains of Potassium Bromide.*

98. ELIXIR QUININÆ COMPOSITUM. *N. F.*

Compound Elixir of Quinine.

Quinine Sulphate	2	Gm.
Cinchonidine Sulphate	1	Gm.
Cinchonine Sulphate	1	Gm.
Aromatic Elixir (U. S. P.)	1000	Cc.

Add the alkaloidal salts to the Aromatic Elixir, and dissolve them by agitation. Finally, filter.

Each fluidounce contains 1 *grain of Quinine Sulphate,*

and ½ grain, each, of Cinchonidine and Cinchonine Sulphates.

Note.—This preparation is intended as a substitute for Elixir of Cinchona in certain cases when the presence of other constituents of Cinchona is deemed unnecessary or objectionable.

If it is desired to impart a color to this Elixir, this may be effected by the addition of 16 Cc. of Compound Tincture of Cudbear (F. 419) to the above quantity.

99. ELIXIR QUININÆ ET PHOSPHATUM COMPOSITUM. *N. F.*

Compound Elixir of Quinine and Phosphates.

Quinine Sulphate	4 Gm.
Ferric Phosphate (U. S. P.)	17.5 Gm.
Potassium Citrate	17.5 Gm.
Syrup of Calcium Lactophosphate (U. S. P.)	250 Cc.
Water	30 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Quinine Sulphate in *six hundred* (600) *cubic centimeters* of Aromatic Elixir, if necessary, with the aid of a gentle heat. Dissolve the Ferric Phosphate and the Potassium Citrate in the Water, and add the solution to that first prepared. Then add the Syrup of Calcium Lactophosphate, and lastly, enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains ¼ grain of Quinine Sulphate, 1 grain of Ferric Phosphate, and about ¾ grain of so-called Calcium Lactophosphate.

100. ELIXIR QUININÆ VALERIANATIS ET STRYCHNINÆ. *N. F.*

Elixir of Quinine Valerianate and Strychnine.

Quinine Valerianate	17.5 Gm.
Strychnine Sulphate	0.175 Gm.
Compound Tincture of Cudbear (F. 419)	15 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Quinine Valerianate and the Strychnine Sulphate with about *five hundred* (500) *cubic centimeters* of Aromatic Elixir, until they are dissolved. Then add the Compound Tincture of Cudbear, and lastly, enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains 1 grain of Quinine Valerianate and $\frac{1}{100}$ grain of Strychnine Sulphate.

101. ELIXIR RHAMNI PURSHIANÆ. *N. F.*

Elixir of Rhamnus Purshiana.

Elixir of Cascara Sagrada.

Fluid Extract of Rhamnus Purshiana (U. S. P.)	250 Cc.
Compound Elixir of Taraxacum (F. 111)	750 Cc.

Mix them. Allow the mixture to stand a few days, if convenient, and filter.

Each fluidrachm represents 15 grains of Rhamnus Purshiana.

102. ELIXIR RHAMNI PURSHIANÆ COMPOSITUM. *N. F.*

Compound Elixir of Rhamnus Purshiana.

Compound Elixir of Cascara Sagrada; Elixir Laxativum; Laxative Elixir.

Fluid Extract of Rhamnus Purshiana (U. S. P.)	125 Cc.
Fluid Extract of Senna (U. S. P.)	75 Cc.
Fluid Extract of Juglans (F. 163)	65 Cc.
Compound Elixir of Taraxacum (F. 111)	735 Cc.

Mix them. Allow to stand a few days, if convenient, and filter.

The average dose of this preparation, for an adult, is one (1) to two (2) teaspoonfuls.

103. ELIXIR RHEI.

Elixir of Rhubarb.

Sweet Tincture of Rhubarb (U. S. P.)	500 Cc.
Deodorized Alcohol	65 Cc.
Water	185 Cc.
Glycerin	125 Cc.
Syrup (U. S. P.)	125 Cc.

Mix them, and filter.

Each fluidrachm represents about 2½ grains of Rhubarb.

104. ELIXIR RHEI ET MAGNESII ACETATIS. *N. F.*

Elixir of Rhubarb and Magnesium Acetate.

Elixir Rhei et Magnesiæ. Elixir of Rhubarb and Magnesia.

Magnesia, calcined	20 Gm.
Acetic Acid (U. S. P.)	a sufficient quantity.
Fluid Extract of Rhubarb (U. S. P.)	125 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Magnesia in *one hundred and fifty* (150) *cubic centimeters* of Acetic Acid, with the aid of a gentle heat, adding, if necessary, a little more Acetic Acid, drop by drop, until the solution is neutral to test-paper. Then add the Fluid Extract and enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter.

Each fluidrachm represents about 4 grains of Magnesium Acetate and 7½ grains of Rhubarb.

105. ELIXIR RUBI COMPOSITUM. *N. F.*

Compound Elixir of Blackberry.

Blackberry Root	160 Gm.
Galls	160 Gm.
Cinnamon, Saigon	160 Gm.
Cloves	40 Gm.
Mace	20 Gm.
Ginger	20 Gm.
Blackberry Juice, recently expressed	3750 Cc.
Syrup (U. S. P.)	1875 Cc.
Glycerin	1875 Cc.
Diluted Alcohol (U. S. P.), a sufficient quantity	
To make	10000 Cc.

Reduce the solids to a moderately coarse (No. 40) powder, moisten it with Diluted Alcohol, and percolate it with this menstruum in the usual manner, until *twenty-five hundred* (2500) *cubic centimeters* of percolate are obtained. To this add the Blackberry Juice, Syrup, and Glycerin, and mix thoroughly.

106. ELIXIR SODII BROMIDI. *N. F.*

Elixir of Sodium Bromide.

Sodium Bromide	175 Gm.
Citric Acid	4 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Bromide and the Citric Acid in about *eight hundred* (800) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter, if necessary.

Each fluidrachm contains 10 grains of Sodium Bromide.

107. ELIXIR SODII HYPOPHOSPHITIS. *N. F.*

Elixir of Sodium Hypophosphite.

Sodium Hyophosphite	35 Gm.
Citric Acid	4 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Hypophosphite and the Citric Acid in about *eight hundred* (800) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter, if necessary.

Each fluidrachm contains 2 grains of Sodium Hypophosphite.

108. ELIXIR SODII SALICYLATIS. *N. F.*

Elixir of Sodium Salicylate.

Sodium Salicylate	85 Gm.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Dissolve the Sodium Salicylate in about *eight hundred* (800) *cubic centimeters* of Aromatic Elixir, by agitation. Then add enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*, and filter, if necessary.

This preparation should be freshly prepared when required for use.

Each fluidrachm contains 5 grains of Sodium Salicylate.

109. ELIXIR STILLINGIÆ COMPOSITUM. *N. F.*

Compound Elixir of Stillingia.

Compound Fluid Extract of Stillingia (F. 176)	250 Cc.
Aromatic Elixir (U. S. P.)	750 Cc.

Mix them, allow the mixture to stand a few days, or longer, if convenient, and filter.

Each fluidrachm represents 15 *minims of Compound Fluid Extract of Stillingia.*

110. ELIXIR STRYCHNINÆ VALERIANATIS. *N. F.*

Elixir of Strychnine Valerianate.

Strychnine Valerianate	0.175 Gm
Acetic Acid (U. S. P.)	a sufficient quantity.
Tincture of Vanilla (U. S. P.)	15 Cc.
Compound Tincture of Cudbear (F. 419)	15 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.

Triturate the Strychnine Valerianate with about *sixty* (60) *cubic centimeters* of Aromatic Elixir, gradually added, and effect complete solution by the addition of one or more drops of Acetic Acid, avoiding an excess. Then add the Tinctures, and lastly, enough Aromatic Elixir to make *one thousand* (1000) *cubic centimeters*. Filter, if necessary.

Each fluidrachm contains $\frac{1}{100}$ *grain of Strychnine Valerianate.*

111. ELIXIR TARAXACI COMPOSITUM. *N. F.*

Compound Elixir of Taraxacum.

Fluid Extract of Taraxacum (U. S. P.)	35 Cc.
Fluid Extract of Wild Cherry (U. S. P.)	20 Cc.
Fluid Extract of Sweet Orange Peel (U. S. P.)	20 Cc.
Fluid Extract of Liquorice (U. S. P.)	60 Cc.
Tincture of Cinnamon (U. S. P.)	35 Cc.
Compound Tincture of Cardamom (U. S. P.)	30 Cc.
Aromatic Elixir (U. S. P.)	800 Cc.

Mix them, allow the mixture to stand several days, if convenient, and filter.

Note.—If a precipitate should make its appearance in this preparation, it ought to be removed by filtration. This Elixir is chiefly intended as a vehicle or corrigent, to cover the bitter taste of Quinine and similar substances.

112. ELIXIR TURNERÆ. *N. F.*

Elixir of Turnera.

Elixir of Damiana.

Fluid Extract of Turnera (F. 178)	150 Cc.
Magnesium Carbonate	30 Gm.
Alcohol	250 Cc.
Glycerin	65 Cc.
Aromatic Elixir (U. S. P.), a sufficient quantity	
To make	1000 Cc.
